Executive Summary

Session Law 2017-209, Section 12 tasked the NC Department of Environmental Quality (NCDEQ) with conducting a nutrient study of the Catawba River and its “major tributar(ies).” NCDEQ’s Division of Water Resources (DWR) monitored nutrients in the Catawba River basin from January to July 2018. DWR staff monitored nutrient concentrations at all 41 existing ambient monitoring stations in the Catawba River basin and added ten new monitoring stations to address data gaps and to respond to potential nutrient problems. Past nutrient monitoring data, watershed land use data, and input from DWR basin planners were used to locate the new stations. The highest mean concentrations for most nutrients were observed in the urbanized areas in the lower portions of the basin. Some streams north and south of Lake Hickory also experienced high mean ammonia concentrations. In general, monitoring stations immediately downstream of where major tributaries entered the mainstem of the Catawba River saw increases in nutrient concentrations while lakes typically acted as nutrient sinks. DWR has also developed a story map to present the findings of the study. The Catawba Nutrient Study story map can be found at the following link:

<https://ncdenr.maps.arcgis.com/apps/MapSeries/index.html?appid=fd48cb721ea2455682c10d79c397659c> or <https://arcg.is/1iyi9u>.

1.0 Introduction

The Catawba River is one of seventeen major river basins in NC. It originates in McDowell County just west of Marion, NC and runs west to east past Hickory, NC where it turns to the south and runs to the South Carolina border between Gastonia and Charlotte, NC (Figure 1). The NC portion of the Catawba River is approximately 225 miles long, and the watershed covers approximately 3,300 square miles. The river basin stretches across two NC Department of Environmental Quality (NCDEQ) regional offices, the Asheville Regional Office (ARO) and the Mooresville Regional Office (MRO). In 1999, due to water quality nutrient over enrichment concerns throughout the Catawba River Basin, the NC General Assembly ratified the Clean Water Act of 1999 (HB 1160, Part VII) which gave the Environmental Management Commission (EMC) the authority to adopt temporary rules to protect the Catawba River Basin. A temporary rule went into effect June 30, 2001 with the permanent *Catawba River Basin: Protection and Maintenance of Existing Riparian Buffers* rule (15A NCAC 02B .0243) taking effect August 1, 2004. This law established 50-foot protected riparian buffers along the mainstem of the Catawba River and its mainstem lakes.

Session Law 2017-209, House Bill 56, Section 12 tasks the NCDEQ with conducting a nutrient study of the Catawba River and its “major tributar(ies).” The language reads as follows:

WATER QUALITY TESTING

SECTION 12. *The Division of Water Resources of the Department of Environmental Quality shall conduct a water quality sampling program for nutrients along the mainstem of the Catawba River, which includes sampling for nutrients above, in, and below each major tributary of the Catawba River. No later than October 1, 2018, the Division shall report the results of the study to the Environmental Review Commission.*

2.0 Study Design

DWR began study development by attempting to define and enumerate major tributaries in the Catawba River basin. The Strahler stream order classification system was used to define a range of stream sizes

typically identified as major tributaries. Based on this range, the streams were enumerated by order. It was assumed that for each tributary included in the study there would be three monitoring stations, upstream of the tributary, downstream of the tributary, and within the tributary. Table 1 presents the order, number of streams by order, and the associated number of monitoring stations. Figure 1 shows the location of the different stream orders in the watershed.

Table 1 - Numbers of Catawba River tributaries by stream order.

Stream Order	Number of Tributaries	Mean Drainage Area (sq mi)	Number of Stations*
5 th	3	318	9
4 th	10	84	30
3 rd	18	23	54

*Assumed need for a station upstream, in, and downstream from each tributary.

The number of needed monitoring stations depended on the stream order and ranged from 9 to 54. At the time of the analysis, there were a total of 41 monitoring stations in the basin. Some existing stations could function as an up-, down-, or instream station, but the study would likely require new monitoring locations. Establishing new monitoring stations can be complicated due to difficulties in finding safe, accessible locations, and regional office staff who primarily conduct the ambient monitoring would have to give up existing duties to cover additional monitoring locations. Recent legislation in Session Law 2018-5 established funding available for sampling/monitoring per- and polyfluoroalkyl substances (PFAS) in North Carolina. One PFAS sampling/monitoring position is being established to reside in the Mooresville Regional Office, which could potentially contribute to future study needs.

Upon consultation with the NC General Assembly, DWR developed a study plan for satisfying the legislative mandate. DWR developed a focus area for the study that included the Catawba River mainstem and major tributaries upstream of Lake Norman and the South Fork Catawba River and major tributaries in Burke and Catawba Counties (See Figure 2). DWR staff conducted a preliminary desktop analysis of existing nutrient data in these areas and identified gaps in monitoring data. DWR focused on areas of concern as determined by land use and known elevated nutrient concentrations.

Figure 1 – Map of the Catawba River basin stream orders.

Figure 2 – Map of the focused study area in the Catawba River basin.

2.1 Existing Data

DWR looked at a variety of existing monitoring data. Where water quality changes over time could be statistically identified, DWR evaluated the data as well as the surrounding land use to determine if additional study was needed in the area. Table 2 details the stream locations in the Ambient Monitoring System (AMS) where DWR had sufficient data to run statistical analyses for total Kjeldahl nitrogen (TKN), nitrate+nitrite (NO_3+NO_2), ammonia as N (NH_3), and total phosphorus (TP), respectively. Seven locations in the focused study area had long term nutrient monitoring data. The locations, parameters, and respective changes over time are also provided in the table.

Figure 3 provides the locations of existing DWR ambient monitoring stations in the study area. At the time of study development, not all monitoring stations in the focused study area were monitored for nutrients and the majority of the monitoring data did not have adequate sample sizes to make a valid statistical analysis. Data from these locations along with chemical and physical parameters collected through the Ambient Lakes System Monitoring Program (ALMP), Fish Community Assessment program, and the Benthic Macroinvertebrate Assessment program were evaluated at the 10-digit hydrologic unit code (HUC) to provide a “big picture” view to help identify watersheds where nutrient concentrations may be higher. Data from all program areas were used with the understanding that they only provided a “snapshot” of the water quality conditions and were not conclusive in indicating where problems may or

may not exist. These data, combined with the AMS data, indicated that watersheds to the north of Lake Hickory and Rhodhiss Lake and the Clark Creek watershed south of Hickory and Newton have the potential for elevated nutrient concentrations. By evaluating the combined data sets to provide DWR a “big picture” view of the basin, it was also noted that there were very few monitoring stations in these portions of the Catawba River basin.

Figure 3 – Map of Existing monitoring stations.

Table 2 – Existing data for monitoring stations in the proposed study area.

Station	Changes Over Time by Parameter*			
	TKN	NO ₂ +NO ₃	NH ₃	TP
Catawba River at SR 1221 NR Pleasant Gardens	Increasing	Decreasing	No Change	No Change
North Fork Catawba River at SR 1552 NR Hankins	Increasing	Decreasing	No Change	Decreasing
Linville River at NC 126 NR Nebo	Increasing	No Change	Increasing	Increasing
Wilson Creek at US221 NR Gragg	Increasing	Decreasing	Increasing	Increasing
Lower Creek at SR 1142 NR Lenoir	No Change	Increasing	No Change	No Change
Lower Creek NR Morganton/Marion (deactivated)	Decreasing	Decreasing	Decreasing	No Change
Jacob Fork at SR 1924 at Ramsey	Increasing	No Change	No Change	Increasing

*Data shown in the table were developed using a seasonal and non-seasonal version of the non-parametric Mann-Kendal trend test to determine temporal trends in water quality. The dataset includes data from 1997-2016. Only stations that had at least 5 years of data and 40 samples during that time period were evaluated. The analysis is to be used as a screening tool and should not be used for other purposes outside of its intended use.

2.2 Additional Monitoring

A preliminary land use survey of the watershed and anecdotal evidence were used in combination with the existing nutrient data to identify data gaps and other streams of concern. Streams identified for closer study included the Upper, Middle, and Lower Little Rivers, and Gunpowder Creek to the north of Lake Hickory; Horseford Creek and Falling Creek near the City of Hickory; Lyle Creek and McLin Creek whose watersheds include portions of the City of Hickory, City of Newton, Town of Conover, Town of Claremont, and Town of Catawba. These streams drain a variety of land uses including agriculture and urban/suburban uses (Figure 4). During field reconnaissance, at least one suitable monitoring location was identified for each of these creeks. These locations (Figure 5) are listed below:

- Upper Little River at Petra Mill Rd. (USGS gage station)
- Middle Little River at Devil Track Rd.
- Lower Little River at Liledoun Rd.
- Gunpowder Creek at Dudley Shoals Rd. (least suitable, could require land owner permission)
- Horseford Creek at Glenn Hilton, Jr. Park
- Falling Creek at 29th Avenue NE and at Cloninger Mill Rd. NE
- Lyle Creek at Highway 70
- McLin Creek at Bethany Church Rd.

Figure 4 – Land use coverage in the Catawba River basin. (Source: National Land Cover Database 2011, www.mrlc.gov, Homer et al., 2015)

As discussed above, existing water quality data suggested that Clark Creek has elevated nutrient concentrations compared with other watersheds in the study area. DWR currently monitors Clark Creek at the confluence with South Fork Catawba River. An additional station was located further up in the watershed on Clark Creek at Rome Jones Rd.

DWR's AMS also had several stations in the focused study area that were not being monitored for nutrients. Nutrient monitoring was included at all stations in the river basin for the purposes of this study. In addition, DWR reached out to municipalities for assistance with nutrient monitoring. The City of Newton and the City of Hickory agreed to allow DWR staff to collect water quality samples at the raw water intakes for their respective water treatment plants. City of Newton has an intake on Jacobs Fork just west of US 321. City of Hickory's intake is on Lake Hickory northeast of US 321 near the Catawba County line.

Figure 5 – Map of new monitoring stations.

2.3 Parameters

For the purposes of this study, “nutrients” were determined to be TP, TKN, NO_3+NO_2 , and NH_3 . Note that $\text{TKN} + \text{NO}_3+\text{NO}_2 = \text{total nitrogen (TN)}$. However, additional parameters were added to the study for increased usability of the results: turbidity, fecal coliform and physical water quality parameters (water temperature, dissolved oxygen, pH, and conductivity). Monitoring for these parameters was conducted in accordance with DWR’s Ambient Monitoring System Quality Assurance Project Plan, July 2017 and Ambient Lakes Monitoring Program Quality Assurance Project Plan, March 2014. Per the respective plans, samples taken in rivers and streams were collected as grab samples while lake samples were collected as a composite of the water column photic zone, defined here as two times the secchi depth.

3.0 Results

Nutrient results and related data were collected from DWR reservoir, river, and stream monitoring station locations during 2007-2018. Appendix A includes a list of all monitoring stations.

Nutrient results from monitoring stations with historic (2007-2016) data were compared to results from the study timeframe, January-July 2018 (nutrient monitoring at some stations began in February 2018). The comparison was made to evaluate the likelihood of obtaining representative data during the study. Median concentrations were compared, as these are most indicative of typical conditions at a given location. Major changes in median nutrient concentrations were not observed between the two timeframes (Appendix B).

Although NC does not have water quality standards for nutrients, all nutrient results from 2007-2018 were compiled and summarized in a process similar to that applied during DWR's assessment of surface waters. It should be noted that the data did not meet all of the requirements for comparison with NC water quality standards. The comparison was conducted to supply a standardized summary of results for each station (Appendix C) only. It can also be used as a screening tool to inform future monitoring actions in the Catawba River basin.

3.1 Basinwide Nutrient Concentrations

Figure 6 presents the mean nutrient concentrations for all monitoring stations in the basin. Mean nutrient concentrations for the lakes and reservoirs were calculated using 2017 data and mean concentrations for streams were calculated using 2018 data. Mean values for most nutrients were highest around the urbanized areas in the lower portions of the watershed. Mean ammonia values were also elevated at the Horseford Creek and downstream Falling Creek and Lower Little River monitoring stations as compared to other watersheds in the basin.

Figure 6 – Mean nutrient values of 2017 ALMP data and 2018 AMS data.

3.2 Location-specific Nutrient Concentrations

Ammonia concentrations were generally below 0.2 mg/L during the study timeframe. Six results were greater than 0.2 mg/L, three of which were from stations in Charlotte and Gastonia at the lower end of the basin. The highest measured value was 0.47 mg/L in Sugar Creek (C9050000). Falling Creek (C2670000), located in Hickory, returned three results over 0.2 mg/L, the second highest study result, and the highest mean concentration (Table 3). In some streams with multiple monitoring stations, including Falling Creek and Lower Little River, average ammonia concentrations were higher at downstream stations (Figure 7).

Table 3 – Monitoring stations with maximum NH₃ concentration greater than 0.2 mg/L.

Station	Location	County	Stream Class	# of Results	Results >0.2 mg/L	Min (mg/L)	Median (mg/L)	Max (mg/L)	Mean (mg/L)

The majority of elevated NO₃+NO₂ concentrations occurred in the lower portion of the basin, where there were four stations that returned multiple results greater than 2.0 mg/L NO₃+NO₂ (Table 4). The highest values were observed at two stations in South Carolina, followed by Little Sugar Creek (C9210000) and Sugar Creek (C9050000) in Charlotte. Three of these stations averaged over 10 mg/L (Figure 7). Mid-basin Clark Creek (C4560000) was the only other project station with results over 2.0 mg/L, with a maximum value of 2.6 mg/L. NO₃+NO₂ results primarily represent nitrate concentrations, as nitrite quickly converts to nitrate in the presence of oxygen.

Table 4 – Monitoring stations with maximum NO₃+NO₂ concentrations greater than 2.0 mg/L.

Station	Location	County	Stream Class*	# of Results	Results >2.0 mg/L	Min (mg/L)	Median (mg/L)	Max (mg/L)	Mean (mg/L)

* Freshwaters (FW) is a South Carolina surface water classification. FW are defined as freshwaters suitable for primary and secondary contact recreation and as a source for drinking water supply after conventional treatment in accordance with the requirements of the Department. Suitable for fishing and the survival and propagation of a balanced indigenous aquatic community of fauna and flora. Suitable also for industrial and agricultural uses.

Several stations (five in NC) had single monitoring events with greater than 1.5 mg/L TKN during the study timeframe, but only two NC streams (Sugar Creek and Little Sugar Creek) returned averages over 1.0 mg/L

TKN (Table 5). In the upper- to mid-basin, individual results over 1.5 mg/L were seen at three stations: C3220000 (Lyle Creek), C2880000 (Lower Little River), and C4560000 (Clark Creek) (Figure 7).

Table 5 – Monitoring stations with maximum TKN concentrations greater than 1.5 mg/L.

*CA – Critical Area – The critical area is defined as extending either 1/2 mile from the normal pool elevation of the reservoir in which the intake is located or to the ridge line of the watershed (whichever comes first); or 1/2 mile upstream from and draining to the intake (or other appropriate downstream location associated with the water supply) located directly in the stream or river (run-of-the-river), or to the ridge line of the watershed (whichever comes first).

Seven stations (five in NC) had at least one result greater than or equal to 0.50 mg/L, and a mean of greater than 0.15 mg/L, total phosphorus (Table 6, Figure 7). C9210000 (Little Sugar Creek) was the only station with a majority of results greater than 1.0 mg/L.

Table 6 – Monitoring stations with maximum TP concentrations greater than or equal to 0.50 mg/L.

Figure 7 – Maps of stations with elevated concentrations by nutrient parameter.

3.3 Major Tributary Influence

Based on the language of the session law, a main goal of the study is to understand the influence major tributaries have on the mainstem of the Catawba River. Figures 8 and 9 show the median and maximum nutrient concentrations, respectively, at monitoring stations along the mainstem of the Catawba River. Moving left to right on the horizontal axes of the graphs represents moving downstream along the river. The confluences of major tributaries are shown by arrows, and bracketed station codes represent lakes. In general, stations immediately downstream of where a major tributary enters the mainstem experience an increase in nutrient concentrations. This is not surprising considering that headwater and smaller order streams which feed the major tributaries make up approximately 75% of stream channel length in a watershed (Snyder et al., 2013). They have a high ratio of stream edge to watershed area and collect the majority of the nonpoint source pollutants entering the watershed (Richardson and Danehy, 2007). The graphs also show that mainstem lakes often act as nutrient sinks. As nutrients enter the lake backwaters, the nutrients settle out with particulate matter or are consumed by algal and aquatic plant communities for primary production within the lake.

Figure 8 – Median nutrient concentrations by mainstem monitoring station for 2017-2018.

Figure 9 – Maximum nutrient concentrations by mainstem monitoring station for 2017-2018.

4.0 Discussion

As noted above, the highly urbanized areas in the lower portions of the basin have the highest observed nutrient concentrations. Urban and suburban areas have a variety of nutrient sources including stormwater from highly developed watersheds, untreated wastewater from sanitary sewer overflows and aging infrastructure, treated wastewater from point source discharges, and industrial sources. The problem is compounded by the lack of significant forested and vegetated areas adjacent to streams capable of taking up the nutrients. The condition of riparian areas, or buffers, along a stream or river play a pivotal role in the integrity of a stream channel and in-stream water quality. While any type of streamside vegetation is desirable, trees provide the greatest amount of benefit and highest potential for meeting water quality and habitat restoration objectives. Intact riparian buffers (grass or trees) can protect water quality by reducing sedimentation and filtering stormwater runoff, thus reducing the amount of nutrients entering the stream (NCSU, 2017). Riparian forested buffers provide shade which controls in-stream water temperature extremes (i.e., prevents direct sunlight from increasing water temperature) (Ibid.). They also stabilize streambanks, protect stream morphology, and enhance biodiversity.

The spatial location of many point sources of pollution are readily available. Figure 10 shows the locations of NPDES point source dischargers in the study area. Many of these facilities are required to keep records of effluent concentrations that can then be used by DWR to assist with identifying impacts to water quality. It is difficult, however, to account for and quantify nonpoint sources of pollution.

Outside of urbanized areas, nutrient inputs shift toward nonpoint sources. Many of the anthropogenic nutrient inputs comes from agricultural sources including animal operations, commercial fertilizer applications, and land application of treated wastes.

Waste from agricultural, industrial and municipal facilities can provide much needed plant nutrients for farmers, landscapers and home gardeners. Examples of operations that can produce waste for land application include food-processing plants, pharmaceutical companies, animal operations, wastewater treatment plants, and wood-product manufacturers. Regardless of the type of waste, it must be analyzed for nutrients and metals before it is land applied to ensure that the amount applied as fertilizer, or as a soil amendment, can be utilized by vegetation (i.e., crops, landscaped areas). If not effectively utilized by vegetation, nutrients can enter surface water by atmospheric deposition, groundwater transport and stormwater runoff. Excess nutrients in surface water can impact aquatic ecosystems, and the type and amount of treatment required to ensure that water is safe for human consumption.

Understanding the impacts from large-scale waste application can be challenging due to minimal monitoring in the watersheds in which they are located. DEQ has regulatory authority over swine and cattle operations that use dry or liquid manure waste management systems and poultry operations that use a liquid waste management system (i.e., spray irrigation). These permitted animal facilities are inspected annually. A Certified Animal Waste Management Plan (CAWMP) is required before a permit is issued or renewed.

Most poultry operations, however, produce a dry litter waste that typically falls under the deemed permitted category (NCAC 02T .1303), and they do not require an NPDES or state permit. Operations that fall into this category are only inspected if a complaint is filed. Because information about the location, number of animals, amount of waste produced or fields on which the dry litter is applied is unknown, determining the extent of potential impacts from poultry waste to water quality is difficult. Often, information about these facilities is restricted due to federal rules and regulations under the United States Department of Agriculture (USDA).

In addition to showing the location of NPDES point source dischargers, Figure 10 also displays the number of chickens and turkeys located in counties partially or entirely in the Catawba River basin based on information from the 2012 Census of Agriculture. The number of chickens and turkeys is just one example of how the number and type of animal in the county can potentially influence the amount of nutrients in the basin. Without knowing the location of deemed permitted operations and land application sites, however, it is difficult for DWR to establish new monitoring stations to assess potential nutrient impacts from animal operations to aquatic ecosystems and water quality. More information about the number and total number of animal operations for the counties located entirely or partially in the basin can be found in Appendix E.

Figure 10 – NPDES locations and poultry populations in the Catawba River basin.

Discharge volumes, also known as streamflow, have two main drivers: precipitation and groundwater baseflow. These drivers are interconnected as groundwater baseflow is dependent on precipitation. Discharge volumes are an important factor in how nutrient inputs affect rivers and streams. Higher flows can dilute nutrient inputs from point and nonpoint sources as well as increase the assimilative capacity of streams. However, precipitation events driving higher discharge flows have more potential to wash in pollutants from the surrounding watershed. In low flow conditions, nutrient inputs have a greater impact on the system, but without precipitation, there is less interaction of the streams with the surrounding watershed.

Using the USGS Exploration and Graphics for River Trends (EGRET) tool, historical stream flow records at five non-Catawba River mainstem USGS stream gages were used to evaluate long-term stream flow changes throughout the Catawba River Basin (Table 7). The results were similar at all five gage stations, with declining flow trend in the annual mean daily flow and the annual 7-day minimum flows starting around 1980. A declining 7-day minimum flow is a possible indicator that groundwater baseflow contributions to these stream systems are on the decline. The minimum in-stream flows are generally most critical periods for aquatic life and can result in lower in-stream assimilative capacity for pollutants and limit habitat suitability. The variability as seen by the increasing standard deviation over time at all the stations is indicative of a larger flow difference between low flows and storm event high flows occurring in all five watersheds. It appears that storm events are becoming less frequent but more intense. Figure 11 provides an example of the stream flow trends at Jacob Fork at Ramsey NC. Stream flow trends for all five gage stations can be found in Appendix D.

Table 7. USGS Gage Stations Used to Assess Long Term Stream Flow Trend Analysis (USGS EGRET).

USGS Station	Station Name and Location	HUC	County	Drainage Area (Square Miles)	Years of Record	Notes

Figure 11. USGS EGRET Stream Flow Analysis Results for Jacob Fork at Ramsey NC (Gage 02143040).

A comparison of streamflow and nutrient concentrations was made for monitoring stations co-located with gage stations at Lower Little River, Henry Fork, Indian Creek, and Jacob Fork (Figures 12, 13, 14, and 15). Very few differences in concentrations were observed, regardless of stream flow, across all nutrient parameters and all monitoring stations. Where concentrations did vary, the differences in concentration were relatively small and did not appear to be due to stream flow.

Figure 12 – Nutrient concentrations v. stream flow at Lower Little River gage station.

Figure 13 – Nutrient concentrations v. stream flow at Henry Fork gage station.

Figure 14 – Nutrient concentrations v. stream flow at Indian Fork gage station.

Figure 15 – Nutrient concentrations v. stream flow at Jacob Fork gage station.

5.0 Next Steps

Four main next steps will be discussed: continue nutrient monitoring, obtain additional information about potential nutrient sources, identification of specific nutrient sources and levels of contribution, and continued protection of riparian buffers.

First, continued monitoring is necessary to accurately identify what the nutrient problems are in the river basin. A basin-scale approach to monitoring nutrients can provide useful data but in very general terms. This is especially true when the study period does not span multiple years. As noted in the results discussion, the short duration of the study did not provide a sample size adequate to conduct valid statistical analyses that could demonstrate potential areas of significantly elevated nutrient concentrations. The most immediate needs for future study are continued monitoring of areas that have demonstrated the potential to have elevated nutrient concentrations. Based on the results discussed above and dependent on available resources, continued monitoring of the new stations established for this study will occur at the following locations:

- Horseford Creek at Glenn Hilton, Jr. Park
- Falling Creek at 29th Avenue NE and at Cloninger Mill Rd. NE
- Lower Little River at Liledoun Rd.
- Clark Creek at Rome Jones Rd.

Monitoring at the remaining new stations will be discontinued due to lack of potential for elevated nutrient concentrations. DWR will continue to monitor nutrients at the existing AMS stations in the Catawba River basin. DWR will also continue to look for opportunities to focus in on watersheds where nutrient concentrations demonstrate problems. This could include establishing new stations in smaller watersheds with elevated nutrients, intensive watershed studies, and/or upstream/downstream monitoring of suspected nutrient sources.

Second, additional information is needed to understand land use changes over time and how the number of animals and types of operations can potentially impact the amount of nutrients in the basin. As discussed in Section 4.0, DEQ has regulatory authority over swine and cattle operations that use dry or liquid manure waste management systems and poultry operations that use a liquid waste management system (i.e., spray irrigation). These permitted animal facilities are inspected annually, and a Certified Animal Waste Management Plan (CAWMP) is required before a permit is issued or renewed. Most poultry operations, however, produce a dry litter waste that typically falls under the deemed permitted category (NCAC 02T .1303) and do not require an NPDES or state permit. Because information about the location, number of animals, amount of waste produced, or fields on which the dry litter is applied is unknown, determining the extent of potential impacts from poultry waste to water quality is difficult to assess. Often, information about these facilities is restricted due to federal rules and regulations under the USDA. Without knowing the location of deemed permitted operations and land application sites, however, it is difficult for DWR to establish new monitoring stations to assess potential nutrient impacts from animal operations to aquatic ecosystems and water quality. More information about the number and total number of animal operations for the counties located entirely or partially in the basin can be found in Appendix E. In order to understand the amount of waste potentially produced in the basin and changes over time, the type, number and weight of the animal would need to be taken into consideration and normalized.

Third, in-depth analysis is needed to identify specific sources of the nutrients. However, identifying sources of elevated nutrient concentrations on a stream reach scale has proven difficult in past studies. Recently, stable isotope and excitation-emission matrix (EEM) fluorescence analyses have become popular in identifying nitrogen sources in ambient waters. Stable isotope analysis examines the ratios of stable N isotopes (N15:N14) (Perkins et al. 2014). Nitrogen sources such as wastewater effluent, fertilizers, and animal wastes have different ranges of isotope ratios. These ratio ranges can act as fingerprints for sources of the nitrogen.

EEM fluorescence analysis can also be used to identify the fluorescent properties of dissolved organic nitrogen (Osburn et al. 2016). Organic nitrogen exhibits different fluorescence signatures depending on the source of the nitrogen. These signatures can be modeled in a parallel factor analysis to identify sources (wastewater, animal waste, septage, etc.) and the relative nitrogen contributions of the sources (Ibid.).

Another analysis that can act as a surrogate for nutrient source identification is genetic testing of pathogens using quantitative polymerase chain reaction (qPCR) analysis. Often anthropogenic nutrient sources are also pathogen sources (domestic wastewater, septage, livestock wastes, etc.). Identifying the sources of the pathogens can provide insight into the sources of the nutrients. Each analysis has its advantages and disadvantages and could assist DWR with identifying nutrient sources and how to address those sources. Several universities across the state have the technology to conduct EEM fluorescence analysis and/or qPCR analysis. Additional resources would be needed to purchase equipment and fund staff in order for DWR to conduct these analysis strategies.

Fourth, as discussed in the introduction, the Catawba River mainstem is subject to the *Catawba River Basin: Protection and Maintenance of Existing Riparian Buffers*. Continued protection of these buffers is critical to reducing nutrient loading to the Catawba River. A multitude of scientific studies have shown that riparian buffers are very effective at removing sediment, nutrients, and other pollutants from surface and subsurface flows before they reach streams and rivers. A 2012 NC Department of Environment and Natural Resources report summarized the pollutant removal efficiencies published by dozens of researchers. One publication that surveyed 45 published papers found that 50-foot buffers remove about 70% of total nitrogen entering the riparian buffers through stormwater while another survey publication found phosphorus removal efficiencies of 46-79% in 30-foot buffers. If the buffer protections were expanded to the tributaries and headwater streams, which make up approximately 75% of a watershed's stream length, water quality could be better protected against developmental impacts.

The additional monitoring discussed above will require additional funds for staff, services, and equipment. The Mooresville Regional Office has recently obtained another ambient monitoring position which will help with staff workload, but additional monitoring equipment would be necessary for smaller scale investigations. Examples of this equipment include additional water quality meters for measuring physical parameters, automated samplers which initiate sampling based on rainfall or other stream flow-based factors, and vehicles for deploying multiple monitoring teams. In addition, the DWR Chemistry Lab has seen a 20% increase in nutrient analyses between 2017 and 2018. The lab would need additional staff and analytical equipment to process the samples associated with intensive studies. Furthermore, funds would be needed to pay for the source identification analyses discussed above (EEM, qPCR, etc.).

and locally weighted scatterplot smooth (solid curve) for JACOB FORK AT RAMSEY, NC for 1960 - 2017.

Appendix E

USDA Agriculture Census Data

Information about the number and types of animal operations in counties located entirely or partially in the Catawba River basin were queried using the 2012 USDA Census of Agriculture. The census and the query are available online: https://quickstats.nass.usda.gov/?source_desc=CENSUS. The census definition of a farm is “any place from which \$1,000 or more of agricultural products were produced and sold, or normally would have been sold, during the census year” (USDA, 2012). For the purposes of this report, the 2002, 2007, and 2012 census was queried for the sector “animals and products”. To remain consistent with the type of information presented, “inventory” was selected as the category and queried for all three census years. Counties included: Alexander, Avery, Burke, Caldwell, Catawba, Gaston, Iredell, McDowell, Mecklenburg, and Union. The number and type of animal operations are included as an appendix to this report to identify potential sources of nutrients in the basin. More in-depth analysis is needed to understand how the number of animals and operations can potentially impact the amount of nutrients in the basin.

The numbers associated with poultry are the total number of animals (broilers, pullets, layers, roosters, and turkeys) and total number of operations with inventory reported at a point in time (end of December) for each census year in each county. The USDA NASS provides a breakdown of the farms by inventory. Inventory numbers are: 1 to 49, 50 to 99, 100 to 399, 400 to 3,199, 3,200 to 9,999, 10,000 to 19,999, 20,000 to 49,999, 50,000 to 99,999, 100,000 or more.

MECKLENBURG	10	9	
UNION	16	8	13
TOTALS	106	174	173

Swine/hog numbers are generally low in the 11 counties located entirely or partially in the basin. The numbers associated with swine/hogs are the total number of animals and total number of operations with inventory reported at a point in time (end of December) for each census year in each county. The USDA NASS provides a breakdown of the farms by inventory. Inventory numbers are: 1 to 24, 24 to 49, 50 to 99, 100 to 199, 200 to 499, 500 to 999, and 1,000 or more. Only Caldwell and Union counties had inventories marked at 1,000 or more.
