Re: 2004 Environmental Legislation

We are pleased to present you with this overview of the Environmental Review Commission and a review of environmental actions taken by the General Assembly in the 2004 Regular Session. The review includes the following documents:

1. Membership of the Environmental Review Commission
2. Authorizing Legislation
3. List of the final disposition of bills recommended by the Environmental Review Commission during the 2004 Session
4. 2004 Summaries: Environment and Natural Resources Legislation
5. Summary of Funding for Environmental Initiatives, 2004 Session
6. Table of Reports by the Environmental Review Commission Required or Authorized by North Carolina Law
7. Table of Reports to the Environmental Review Commission Required or Authorized by North Carolina Law

ENVIRONMENTAL REVIEW COMMISSION
2003-2004

Senator Charlie Albertson, Co-chair
136 Henry Dunn Pickett Road
Beulaville, NC 28518
(910) 298-4923

Representative Pryor Gibson, III, Co-chair
P. O. Box 1010
Wadesboro, NC 28170
(704) 694-5957

Senator Daniel G. Clodfelter, Co-Chair

North Carolina General Statutes
ARTICLE 12D.

Environmental Review Commission.

§ 120-70.41. Commission established.

The Environmental Review Commission is hereby established.

§ 120-70.42. Membership; cochairs; vacancies; quorum.

(a) The Environmental Review Commission shall consist of six Senators appointed by the President Pro Tempore of the Senate, six Representatives appointed by the Speaker of the House of Representatives, who shall serve at the pleasure of their appointing officer, the Chair or a Cochair of the Senate Committee on Agriculture, Environment, and Natural Resources or the equivalent committee, the Chair or a Cochair of the House of Representatives Committee on Environment and Natural Resources or the equivalent committee, the Chair or a Cochair of the Senate Committee on Appropriations – Natural and Economic Resources or the equivalent committee, and the Chair or a Cochair of the House of Representatives Committee on Appropriations – Natural and Economic Resources or the equivalent committee.

(b) The President Pro Tempore of the Senate shall designate one Senator to serve as cochair and the Speaker of the House of Representatives shall designate one Representative to serve as cochair.

(c) Except as otherwise provided in this subsection, a member of the Commission shall continue to serve for so long as the member remains a member of the General Assembly and no successor has been appointed. A member of the Commission who does not seek reelection or is not reelected to the General Assembly may complete a term of service on the Commission until the day on which a new General Assembly convenes. A member of the Commission who resigns or is removed from service in the General Assembly shall be deemed to have resigned or been removed from service on the Commission. Any vacancy that occurs on the Environmental Review Commission shall be filled in the same manner as the original appointment.

(d) A quorum of the Environmental Review Commission shall consist of nine members.

§ 120-70.43. Powers and duties.

(a) The Environmental Review Commission shall have the following powers and duties:

(1) To evaluate actions of all boards, commissions, departments, and other agencies of the State and local governments as such actions relate to the environment or protection of the environment, including but not limited to an evaluation of:

a. Benefits of each program relative to costs;

b. Achievement of program goals;

c. Use of measures by which the success or failure of a program can be measured; and

d. Conformity with legislative intent;

(2) To study on a continuing basis the organization of State government as it relates to the environment or to the protection of public health and the environment, including but not limited to:

a. Improvements in administrative structure, practices, and procedures;

b. Increased integration and coordination of programs and functions;

c. Increased efficiency in budgeting and use of resources;

d. Efficient administration of licensing, permitting, and grant programs;

e. Prompt, effective response to environmental emergencies;

f. Opportunities for effective citizen participation; and

g. Broadening of career opportunities for professional staff;

(3) To make any recommendations it deems appropriate regarding the reorganization and consolidation of environmental regulatory agencies and the recodification of statutes relating to the environment, including but not limited to:

a. Ways in which agencies may operate more efficiently and economically;

b. Ways in which agencies can provide better services to the State and to the people; and

c. Instances in which functions of agencies are duplicative, overlapping, incomplete in scope or coverage, fail to accomplish legislative objectives, or for any other reason should be redefined or redistributed;

(4) To review and evaluate changes in federal law and regulations, relevant court decisions, and changes in technology affecting the environment or protection of the environment;

(5) To review existing and proposed State law and rules affecting the environment or protection of the environment and to determine whether any modification of law or rules is in the public interest;

(6) To make reports and recommendations, including draft legislation, to the General Assembly from time to time as to any matter relating to the powers and duties set out in this section; and

(7) To undertake such additional studies as it deems appropriate or as may from time to time be requested by the President Pro Tempore of the Senate, the Speaker of the House of Representatives, either house of the General Assembly, the Legislative Research Commission, the Joint Legislative Commission on Governmental Operations, the Joint Legislative Utility Review Committee, or the Joint Select Committee on

Low-Level Radioactive Waste and to make such reports and recommendations to the General Assembly regarding such studies as it deems appropriate; provided that the Environmental Review Commission shall not undertake any study which the General Assembly has assigned to another legislative commission or committee.

(b) The Environmental Review Commission may continue the study of environmental agency consolidation and reorganization. The study of environmental agency consolidation shall include, but is not limited to:

(1) Monitoring the implementation of Session Laws 1989, c. 727;

(2) Evaluation of the organization, programs, and operation of the Department of Environment and Natural Resources;

(3) Evaluation of the organization, functions, powers, and duties of the components of the Department of Environment and Natural Resources, including boards, commissions, councils, and regional offices; and

(4) Recodification of the General Statutes relating to the environment and environmental agencies.

(c) In addition to its general powers and duties, the Environmental Review Commission shall have the following powers and duties with respect to hazardous waste management:

(1) To study the current and projected need for hazardous waste treatment, storage, and disposal capacity in the State in light of anticipated generation of hazardous waste and alternatives for hazardous waste treatment and disposal;

(2) To evaluate the potential for the development of additional hazardous waste treatment, storage, and disposal capacity by the private sector;

(3) To study the necessity for and scope of hazardous waste treatment, storage, and disposal facilities which are sited, owned, or operated by the State;

(4) To review progress in securing a volunteer county to host a hazardous waste treatment facility;

(5) To study incentives and compensation for the community which hosts, either voluntarily or involuntarily, a hazardous waste treatment facility, including any additional incentives and compensation which may be needed, whether there should be differential compensation for a volunteer county, options for use of funds by local governments, distribution of compensation among local governments, and methods of providing flexibility in the development of an incentives and compensation package for a particular local community;

(6) To review progress in developing interstate agreements for the treatment, storage, and disposal of hazardous waste;

(7) To assist in the development of cooperative, comprehensive regional approach to hazardous waste treatment and disposal;

(8),(9) Repealed by Session Laws 2001-474, s. 12.

(10) To study the capacity assurance requirement under the Comprehensive Environmental Response, Compensation and Liability Act of 1980, Pub. L. No. 96-510, 94 Stat. 2767, 42 U.S.C. 9601 et seq., as amended, and the Superfund Amendments and Reauthorization Act of 1986, Pub. L. No. 99-499, 100 Stat. 1613, as amended as it relates to the continued eligibility of North Carolina for remedial actions under Superfund;

(11) To study alternatives available to the State for dealing with hazardous waste and the ramifications of those alternatives; and

(12) To receive and evaluate reports of every State agency, board, and commission which has any power or duty with respect to hazardous waste management.

§ 120-70.44. Additional powers.

The Environmental Review Commission, while in the discharge of official duties, may exercise all the powers provided for under the provisions of G.S. 120-19, and G.S. 120-19.1 through G.S. 120-19.4. The Environmental Review Commission may meet at any time upon the call of either cochairman, whether or not the General Assembly is in session. The Environmental Review Commission may meet in the Legislative Building or the Legislative Office Building upon the approval of the Legislative Services Commission.

Notwithstanding any rule or resolution to the contrary, proposed legislation to implement any recommendation of the Environmental Review Commission regarding any study the Environmental Review Commission is authorized to undertake or any report authorized or required to be made by or to the Environmental Review Commission may be introduced and considered during any session of the General Assembly.

§ 120-70.45. Compensation and expenses of members.

Members of the Environmental Review Commission shall receive subsistence and travel expenses at the rates set forth in G.S. 120-3.1.

§ 120-70.46. Staffing.

The Legislative Services Officer shall assign as staff to the Environmental Review Commission professional employees of the General Assembly, as approved by the Legislative Services Commission. Clerical staff shall be assigned to the Environmental Review Commission through the offices of the Supervisor of Clerks of the Senate and Supervisor of Clerks of the House of Representatives. The expenses of employment of clerical staff shall be borne by the Environmental Review Commission.

§ 120-70.47. Funding.

From funds available to the General Assembly, the Legislative Services Commission shall allocate monies to fund the work of the Environmental Review Commission.

Environment and Natural Resources Legislation
2004 Regular Session of the 2003 General Assembly

Tim Dodge (TD), George F. Givens (GG), Jeff Hudson (JH), and Jennifer McGinnis (JM)

Enacted Legislation

Coastal Development

Hatteras Village/Temporary Unvegetated Beach Area

S.L. 2004-1 (HB 1411) designates certain oceanfront areas on Hatteras Island as temporary unvegetated beach areas. The affected properties include the oceanfront areas on Hatteras Island west of the new inlet breach in Dare County where the vegetation line was destroyed by Hurricane Isabel on September 18, 2003, and by the construction of an emergency berm. The act allows oceanfront setbacks for new development or redevelopment to be measured from the vegetation line that is depicted in Dare County orthophotographs dated February 4, 2002 through February 10, 2002. The designation will continue until stable, natural vegetation is reestablished or until the Coastal Resources Commission permanently designates the area as an unvegetated beach area by rule.

This act became effective May 26, 2004. (TD)

New Urban Waterfront Development Pilot

S.L. 2004-117 (SB 732) directs the Coastal Resources Commission (CRC) to implement a pilot project under which one county may designate an area as a new urban waterfront (NUW). A NUW area, as defined by the act, is an area designated for development that includes a mixture of residential and commercial uses, recreational areas, and facilities for governmental or other civic purposes; provides for pedestrian access to residential, commercial, civic, and recreational areas; and incorporates open space for recreational and other public purposes. Under the pilot project, a developer could submit an application for a major development permit pursuant to the Coastal Area Management Act of 1974 (CAMA) for development in the NUW area subject to certain requirements, including obtaining a National Pollutant Discharge Elimination System (NPDES) permit for stormwater management prior to commencement of any construction of the development.

Current rules adopted under CAMA define urban waterfronts as areas that lie wholly within the corporate limits of a municipality and are located in either a central business district where there is minimal undeveloped land, mixed land uses, and urban level services such as water, sewer, and streets, or in an industrial zoned area adjacent to a central business district. These rules subject development in urban waterfronts to special use standards with regard to requirements for riparian buffers along shorelines and limits on construction of impervious surfaces. Current rules do not allow for the creation of additional urban waterfronts.

The act authorizes development in the NUW area to the same extent and subject to the same use standards and permitting requirements as development within areas designated as urban waterfronts under rules adopted under CAMA, except that the NUW area must be located outside of the corporate limits of any municipality and development in the NUW area must comply with a 30-foot buffer requirement along all natural shorelines.

If the development in the NUW area fails to include commercial development, civic development, and open space substantially in accordance with the development proposed in the application for the major development permit within six years of the date of issuance of the major development permit, the act provides that the developer must provide mitigation for encroachment into riparian buffers that would otherwise be required under standards adopted by the CRC for development on public trust and estuarine shorelines.

The act also directs the CRC to evaluate the impacts on water quality and other environmental impacts from the development, and the costs and benefits of the development and annually report its interim findings and recommendations to the Environmental Review Commission beginning October 1, 2005, and to report its final findings and recommendations no later than October 1, 2010.

This act became effective July 17, 2004. (JM, GG)

Environmental Health

Septic System Setbacks for Pre-1977 Lots

S.L. 2004-140 (SB 1202) reduces the minimum horizontal separation distance requirements between two subsurface wastewater disposal systems from 20 feet to 10 feet under certain circumstances. The act allows the installation and operation of a subsurface wastewater disposal system that will be located 10 feet or more from an existing subsurface wastewater disposal system if the lot or tract of land on which the new system will be located meets the following criteria:

- The lot was platted prior to July 1, 1977.
- The system will be operated in Soil Group I soils (sandy texture soils, which are primarily found in the Coastal Plain and in the Sandhills area of the State).
- The lot is of insufficient size to allow the minimum horizontal separation distance requirements for a conventional wastewater system.
- The system will receive sewage from only one single-family residence not to exceed four bedrooms.
- The residence is not capable of being served by a public or community wastewater system at the time construction of the system commences.

This act became effective July 29, 2004, and applies to applications for permits made on or after that date. If the Commission for Health Services adopts a permanent rule to implement the provisions of the act, the act will expire when the permanent rule becomes effective. (TD)

Water Conservation/Submeters

S.L. 2004-143 (HB 1083) modifies the requirements for landlords who submeter and charge tenants for providing water or sewer service in apartment complexes, mobile home parks, and other multi-family housing units. The act authorizes the Utilities Commission (Commission) to adopt procedures to allow landlords to submeter and charge for providing water or sewer service. All charges for water or sewer service must be based on the tenant's metered consumption of water and not by any partial measurement of water consumption, unless specifically authorized by the Commission. The rate charged by the landlord may not exceed the unit consumption rate charged by the supplier of water or sewer service. The landlord may, however, charge a reasonable administrative fee for providing water or sewer service.

The act directs the Commission to develop an application that landlords must submit for authority to charge for water or sewer service. The Commission must approve or disapprove an application within 30 days of the filing of a completed application with the Commission. If the Commission has not issued an order disapproving a completed application within 30 days, the application shall be deemed approved. In order to change the rate or administrative fee, a provider must file a notice of revised schedule of rates and fees with the Commission. A notification of revised schedule of rates and fees becomes effective upon 14 days notice to the Commission, unless otherwise suspended or disapproved by an order issued by the Commission within 14 days after filing.

The act also:

- Prohibits landlords from disconnecting or terminating a tenant's water or sewer service due to the tenant's nonpayment of the costs for water and sewer services.
- Prohibits landlords from charging tenants a late fee because of the tenant's failure to pay for water or sewer services.
- Restates that landlords may not use nonpayment of the costs for water or sewer services owed by a tenant as a basis for termination of a lease or eviction.

- Requires a landlord to notify tenants of any violations of water quality standards under the North Carolina Drinking Water Act if the landlord is charging for the cost of providing water or sewer service and has knowledge of the contamination.
- Clarifies the responsibility for monitoring, analysis, and record keeping, as well as for the operation, maintenance, or repair of the providing water system.
- Exempts landlords that submeter and charge for providing water and sewer service from certain bonding and reporting requirements generally required by the Commission.

This act became effective August 1, 2004. (TD, GG)

Fisheries

Under Dock Oyster Culture Program

S.L. 2004-124, Sec. 12.7B (HB 1414, Sec. 12.7B) establishes the Under Dock Oyster Culture Permit Program (Program), which authorizes the holder of a permit to attach up to 90 square feet of oyster cultivation containers to a dock or pier owned by the permit holder. Permit applications must be submitted to the Director of the Division of Marine Fisheries who will issue a permit only if the Director determines that:

- The dock or pier is not located in polluted waters.
- The applicant has satisfied training requirements adopted by the Marine Fisheries Commission.
- The oyster culture activities are compatible with all lawful uses by the public of other marine and estuarine resources, such as navigation, fishing, and recreation.

It is unlawful for a permit holder to sell oysters cultivated under the permit and a permit will be revoked if the permit holder fails to comply with the requirements of the Program.

This section became effective July 1, 2004. (JH)

Amend Fishery Management Plan Requirements

S.L. 2004-160 (HB 1429) amends the requirements for development of Fishery Management Plans (FMPs) so that each FMP will include:

- Conservation and management measures that will attain a "sustainable harvest" rather than an "optimal yield." "Sustainable harvest" is the amount of fish that can be taken from a fishery on a continuing basis without reducing the stock biomass of the fishery or causing the fishery to become overfished.
- A specific time period for ending overfishing and achieving a sustainable harvest. This provision only applies to fisheries that are overfished and does not apply to a fishery where the biology of the fish or the environmental conditions would make ending overfishing and achieving a sustainable harvest within 10 years impracticable.

This act became effective August 2, 2004. (JH)

Amend Shellfish Laws

S.L. 2004-150 (HB 1427) makes the following changes to the law governing shellfish cultivation leases:

- Changes shellfish cultivation lease fees as follows:
  - Increases the initial application filing fee for a bottom shellfish cultivation lease from $100.00 to $200.00.
  - Increases the renewal application filing fee for a bottom shellfish cultivation lease from $50.00 to $100.00.
  - Increases the annual rental fee for a bottom shellfish cultivation lease from $5.00 per acre to $10.00 per acre.

- Alters the annual rental fee for a 5-year water column shellfish cultivation lease from $100.00 for the first four years and $500.00 for the fifth year to $100.00 per year for all five years.

➢ Directs the Marine Fisheries Commission (MFC) to adopt rules to establish training requirements for persons who apply for shellfish cultivation leases. The training requirements will be designed to encourage the productive use of shellfish cultivation leases. The training requirements will not apply to a person who already holds a shellfish cultivation lease that is meeting shellfish production requirements.

➢ Adds failure to comply with the training requirements to the list of conditions for which a shellfish cultivation lease may be terminated.

➢ Authorizes the MFC to study whether and how to establish a process by which shellfish cultivation leases that have been terminated may be leased without reverting to public bottom.

➢ Authorizes the MFC to study issues related to corporate ownership of shellfish cultivation leases.

The provisions changing the fees for shellfish cultivation leases become effective July 1, 2005. All other provisions of this act became effective August 2, 2004. (JH)

Saltwater Fishing Fund/Holdover Appointments

S.L. 2004-187, Secs. 1-4 and 6-13 (HB 831, Secs. 1-4 and 6-13), as amended by S.L. 2004-124, Sec. 12.16 (HB 1414, Sec. 12.16), establish the North Carolina Saltwater Fishing Fund and a program for the licensing of coastal recreational fishing.

North Carolina Saltwater Fishing Fund. – The North Carolina Saltwater Fishing Fund (Fund) is established as a nonreverting fund in the office of the State Treasurer to receive license revenues. The State Treasurer will invest the assets of the Fund and disburse investment income only as directed by the Board of Trustees of the North Carolina Saltwater Fishing Fund (Board). State agencies, local governments, and nonprofit corporations whose primary purpose is conserving, preserving, or restoring the State's marine resources are eligible to apply for a grant from the Fund. The Board may authorize disbursement for:

➢ Resource and habitat enhancement;

➢ Fisheries management research for specifically designated species;

➢ Acquisition of land that provides for the enhancement of fishery habitat or public access to coastal fishing waters;

➢ Purchase or construction of public beach access areas and public marinas; (if the Board purchases or constructs a public marina, it may establish a boat docking fee.)

➢ Emergency dredging for the restoration of access to public fishing areas;

➢ Establishment of scholarships for individuals pursuing degrees in marine sciences; and

➢ Administrative and operating expenses of the Board (no more than 2% of the annual Fund balance or $1,250,000, whichever is greater, may be used).

The Board may not authorize disbursement for law enforcement. The Board will be composed of eleven members as follows:

➢ Three members, each of whom holds a saltwater fishing license (SFL), to be appointed by the Governor;

➢ Three members, each of whom holds a SFL, to be appointed by the Speaker of the House of Representatives;

➢ Three members, each of whom holds a SFL, to be appointed by the President Pro Tempore of the Senate;

➢ The Director of the Division of Marine Fisheries (Division) or the Director's designee (*ex officio* and non-voting); and

➢ The Chair of the Marine Fisheries Commission (MFC) or the Chair's designee (*ex officio* and non-voting).

The Chair of the Board will report to the Joint Legislative Commission on Seafood and Aquaculture by September 30 of each year on the source and amounts of monies credited to the Fund and the purpose and amount of all expenditures from the Fund during the prior fiscal year.

General provisions governing saltwater fishing licenses. –

- It is unlawful for an individual to engage in recreational fishing in coastal fishing waters without having purchased a SFL. An individual may engage in recreational fishing by means of recreational gear without holding a SFL if the individual is 18 years of age or younger and is currently enrolled in school and is making progress toward obtaining a high school diploma or its equivalent.
- A SFL does not authorize the license holder to sell fish taken under the license.
- Any SFL may be purchased or renewed at designated offices of the Division; from the Division by mail, electronic mail, the Internet, or telephone; or at locations designated by the Board.

Types of Saltwater Fishing Licenses.

License Type	Fee	Duration
1-year SFL	$15.00	Valid for a period of one year from the date of issuance
2-year SFL	$30.00	Valid for a period of two years from the date of issuance
3-year SFL	$45.00	Valid for a period of three years from the date of issuance
7-day SFL	$1.00	7 day duration, but may be purchased only once per year
Subsistence SFL	No charge	Valid for a period of one year from the date of issuance
Lifetime SFL:		Lifetime duration
Younger than 6 years of age	$100.00	
6 to younger than 11 years of age	$150.00	
11 to younger than 18 years of age	$200.00	
18 years of age and older	$500.00	

Miscellaneous Provisions. –

- The MFC will adopt rules to define recreational gear and commercial gear.
- The MFC and the Division may not disclose personal information provided by a license applicant.
- The Board shall develop a plan for the implementation of the licensing provisions of the act and study the creation of a unified fishing license for inland and coastal fishing. The Board will report to the Joint Legislative Commission on Seafood and Aquaculture on the plan and study no later than April 15, 2005.
- The act appropriates up to $5,000,000 from the General Fund to the North Carolina Saltwater Fishing Fund for fiscal year 2004-2005 to be used by the Board to implement the act. The Board will repay the $5,000,000 to the General Fund by July 1, 2010. (**Note:** S.L. 2004-124, Sec. 12.16 (HB 1414, Sec. 12.16) provides that if HB 831 becomes law, the appropriations section is repealed. Instead, Sec. 12.16 provides that of the funds appropriated to the Department of Environment and Natural Resources for the 2004-2005 fiscal year, the Division may use up to $450,000 and the Board may use up to $300,000 to implement HB 831. The Board shall repay all of these funds to the General Fund by July 1, 2008.)

The licensing provisions become effective January 1, 2006. With the exception of the appropriations section, Section 13, which was repealed by S.L. 2004-124, Sec. 12.16, all other provisions of this act became effective August 17, 2004.

Section 5 of this act provides that vacancies may be filled in certain offices during a holdover period. For additional information on this section, see **State Government**. (JH)

Parks and Public Spaces

State Parks System Additions & Study

S.L. 2004-24 (HB 1574) authorizes the Department of Environment and Natural Resources to add the Lower Haw River State Natural Area to the State Parks System. The Lower Haw River State Natural Area will be located in Chatham County where the Haw River enters Jordan Lake. This stretch of the Haw River is considered nationally significant for its biological resources including, rare species of fish (Cape Fear Shiner), mussels (Brook Floater), and dragonflies (Septima's Clubtail). Along the river's edge, scenic bluffs and rock outcrops alternate with areas of high quality floodplain forests. In addition to its biological significance, the river is used extensively by canoeists and kayakers who value its rapids and rocky islands.

This property is contiguous with property of Jordan Lake State Recreation Area. The Division of Parks and Recreation (Division) proposes to manage the Lower Haw River State Natural Area as a satellite of Jordan Lake State Recreation Area, using staff from the Recreation Area. Recreational development of the State Natural Area will be limited to trails, canoe access, and associated parking. The State Natural Area is not suitable for campgrounds and similar intensive uses, which are available nearby at Jordan Lake State Recreation Area.

The act also directs the Division to study the establishment of a new State recreation area at Blewett Falls Lake and report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission on or before December 1, 2005.

This act became effective June 25, 2004. (JM)

State Nature & Historic Preserve Removals

S.L. 2004-25 (HB 1607) removes property from the State Nature and Historic Preserve (Preserve) and the State Parks System (System). The act:

- Removes a portion of two parcels at Hemlock Bluffs State Natural Area from the Preserve that are needed by the Town of Cary for a right-of-way for the widening of Kildaire Farm Road. This property must be removed from the Preserve before the State can grant easements to the Town of Cary for the right-of-way. The property was purchased with funds from the Federal Land and Water Conservation Fund, thus restrictions cover the property and require that the property be replaced. The Town of Cary plans to acquire additional property that is adjacent to the existing Natural Area, some of which will be used to replace the property used for the road right-of-way.
- Removes the Horne Creek Living Historical Farm located within the boundaries of Pilot Mountain State Park from the System to allow the property to be reallocated to the Department of Cultural Resources.

This act became effective June 25, 2004. (JM)

Twenty-Four Hour Access to Fort Fisher State Recreation Area During the Fall and Winter/Funds for Department Study/Activities at Fort Fisher

S.L. 2004-124, Sec. 12.3 (HB 1414, Sec. 12.3) provides that members of the public who pay a fee for access to Fort Fisher State Recreation Area (Fort Fisher) may have 24-hour access to the beach at Fort Fisher from September 15 through March 15 of each year.

The section also directs the Department of Environment and Natural Resources (DENR) to conduct a study of vehicle use at Fort Fisher including consideration of:

- The demand for vehicle access to the beach during different times of the year;
- The impact of vehicles on sea turtles and nesting birds;
- The sea turtle and bird nesting activity at Fort Fisher as compared with the nesting activity on the adjoining beach managed by the Bald Head Conservancy and on Masonboro Island; and
- The economic impact of restricting 24-hour vehicle access to the beach.

DENR must report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission by February 1, 2005. The section also provides that of the funds appropriated to DENR for the 2004-2005 fiscal year, $25,000 shall be used to conduct the study and for other educational, conservation, and enforcement activities at Fort Fisher.

This section became effective July 1, 2004. (JM)

One-time Grant to Swain County

S.L. 2004-124, Sec. 12.11 (HB 1414, Sec. 12.11) directs the Wildlife Resources Commission to provide a one-time grant of $37,500 for the 2004-2005 fiscal year from the Wildlife Resources Fund to Swain County as compensation for the loss of ad valorem taxes associated with the purchase by the Wildlife Resources Commission of the 3,431 acre Needmore game lands property located on the Little Tennessee River in Swain County.

This section became effective July 1, 2004. (TD)

Delay Dollar Limit on Credit for Partnerships

S.L. 2004-134 (HB 1602) postpones until 2006 (previously 2005) the imposition on partnerships and limited liability companies of the dollar amount limitation on the credit allowed for real property donations and provides that the Revenue Laws Study Committee should study the credit.

This act became effective July 29, 2004. (CA)

Underground Storage Tanks

Leaking Petroleum Underground Storage Tank Cleanup Funds Solvency

S.L. 2004-124, Sec. 30.10 (HB 1414, Sec. 30.10) allocates additional funds from the motor fuels tax to the Commercial Leaking Petroleum Underground Storage Tank (UST) Cleanup Fund and the Noncommercial Leaking Petroleum UST Cleanup Fund (UST Funds) and makes other changes to the Leaking Petroleum UST Cleanup Program.

Allocation of Funds. – The sum of $19 million is to be credited to the UST Funds and to the Water and Air Quality Account in September 2004 and an additional fractional amount is to be credited throughout the 2004-2005 fiscal year. The act also appropriates funds from the Commercial Fund for one new accounting tech position and to cover legislative salary increases for UST program staff.

Preapproval. – The act authorizes the Department of Environment and Natural Resources (DENR) to identify and develop a list of tasks that require preapproval. DENR may not approve any tasks that require preapproval unless DENR determines that sufficient funds will be available to pay the claim for reimbursement within 90 days after the claim has been approved.

There are two exceptions to the limitation on preapproval of UST work:

- First, at the request of the UST owner, operator, or landowner, DENR may preapprove tasks when sufficient funds are not available to pay the claim for reimbursement within 90 days if the owner, operator, or landowner agrees that the claim will not be paid until after DENR has paid all claims for reimbursement that were submitted through the normal preapproval process.
- Second, DENR may preapprove tasks if the discharge or release creates an emergency situation. These tasks may be reimbursed on the same basis as those approved through the normal preapproval process.

The act provides that this provision does not invalidate any existing rules concerning pre-approval of UST work.

Prioritization of noncommercial sites. – The act directs DENR to establish the degree of risk to human health and the environment posed by noncommercial UST releases and to determine a schedule for

further assessment and cleanup based on those factors. Once DENR has established a cleanup schedule, the costs of any assessment or cleanup activities are not eligible for reimbursement from the Noncommercial Fund until the actions are authorized by DENR pursuant to the schedule. An owner, operator, or other person may choose to undertake assessment or cleanup before receiving authorization from DENR, but the costs for the assessment or cleanup will be reimbursed only after DENR has paid or reimbursed the costs for all assessments and cleanups authorized by DENR. A similar provision that applies to commercial UST releases was enacted in 2003. The prioritization requirements will expire on October 1, 2005.

Study UST Program. – The act directs the Environmental Review Commission (ERC) and the Joint Legislative Transportation Oversight Committee to jointly study the role of the State and DENR in implementing the UST cleanup program. The issues to be considered include:

- The role of the State in assisting owners and operators of USTs in meeting applicable financial responsibility requirements and the availability and adequacy of private insurance.
- The adequacy of current and projected future revenue into the UST Funds.
- The feasibility and desirability of privatizing some or all of the functions of the UST Funds.
- The State's role in the cleanup of orphan UST sites.
- Whether existing UST rules are adequate to prevent future releases from USTs.

The ERC and the Joint Legislative Transportation Oversight Committee are to report the results of their study, including any legislative proposals, to the General Assembly no later than January 31, 2005.

The portions of this section that address prioritization and preapproval become effective October 1, 2004. The remainder of the section became effective July 1, 2004. The portions that address prioritization expire on October 1, 2005. (GG, TD)

Water Quality/Quantity/Groundwater

Dry-Cleaning Solvent Cleanup Act Amendments

S.L. 2004-48 (SB 1219) increases the percentage of revenue credited to the Dry-Cleaning Solvent Cleanup Fund (Fund) that may be used to pay for the costs of assessment or remediation of dry-cleaning solvent contamination that occurred prior to July 1, 2001, to 25% of the revenues credited to the Fund in the preceding fiscal year. Previously, the total payments made for the costs of assessment or remediation that occurred prior to July 1, 2001 could not exceed 10% of the revenues credited to the Fund in the preceding fiscal year.

The act became effective July 1, 2004. (TD)

Limit Use of Impervious Parking Surfaces For Sale of Nursery Stock

S.L. 2004-124, Sec. 6.29 (HB 1414, Sec. 6.29) makes changes to the law concerning the regulation of stormwater runoff. This section provides that a retail merchant may not use more than 400 square feet of impervious surface within the merchant's vehicular parking area for the display and sale of nursery stock as defined by the Board of Agriculture. The Board defines nursery stock as all wild or cultivated plants trees, shrubs, vines, and bulbs. This definition specifically excludes, however, annual plants, cut flowers, true seeds, decorative plants without roots, and perennial plants intended for indoor use that are produced in North Carolina.

This section does not apply to retail merchants that either:

- Collect or treat stormwater on-site using a treatment system that is designed to remove at least 85% of total suspended solids.
- Collect or store stormwater for reuse on-site for irrigation or other purposes.
- Collect and discharge stormwater to a local or regional stormwater collection and treatment system.

The Secretary of Environment and Natural Resources may impose a civil penalty of not more than $25,000 for a violation of this section. For continuous violations, this penalty may be imposed per day, unless otherwise stipulated. A civil penalty of $10,000, or in the case of a continuous violation, a penalty of $10,000 per day may be assessed if a civil penalty had been imposed against the violator within the five years preceding the violation.

This section becomes effective January 1, 2005, and applies only to retail merchants that first open a retail premises for business on or after that date or that submit an application for a building permit for the construction or renovation of a retail premises after that date. (TH)

Stormwater Pilot Project

S.L. 2004-124, Sec. 30.20 (HB 1414, Sec. 30.20) directs the Department of Transportation to use up to $15,000,000 of funds available to the Department during the 2004-2005 fiscal year for a stormwater pilot project that will use new and innovative technologies and filtering mechanisms to clean up State-maintained ocean outfalls and associated outlets.

This section became effective July 1, 2004. (TD)

Phase II Stormwater Management-1

S.L. 2004-163 (SB 1210) provides for the temporary implementation of federal Phase II stormwater management requirements.

Phase II Stormwater Permit Application and Standards. – Section 1 provides that an application for a Phase II National Pollutant Discharge Elimination System (NPDES) permit for stormwater management (stormwater permit) that was submitted to the Department of Environment and Natural Resources (DENR) in accordance with the application schedule set out in Section 6 of the temporary Phase II stormwater management rule adopted by the Environmental Management Commission (EMC) on October 10, 2002, will be deemed timely received. A local government applicant for a stormwater permit must develop, implement, and enforce a stormwater management plan that is approved by DENR and that meets federal requirements. The evaluation of the stormwater permit applications by DENR will be conducted as provided in Section 10 of the temporary Phase II stormwater management rule adopted by the EMC on October 10, 2002, as modified by this act. A municipality with a population of less than 1,000 is not required to obtain a stormwater permit unless the municipality is shown to be contributing to an impairment of State waters.

New Development and Redevelopment in Unincorporated Areas of Counties. –Section 2 provides that new development and redevelopment located in the unincorporated area of a county must comply with the stormwater management standards set forth in Section 10 of the temporary Phase II stormwater management rule adopted by the EMC on October 10, 2002, as modified by this act, beginning July 1, 2006 if the new development or redevelopment is located in:

- An area that is federally designated as an urbanized area.
- An unincorporated area of a county that is delineated as a regulated coverage area. An unincorporated area is delineated as a regulated coverage area based on its geographical proximity to a municipality and the environmental impact of stormwater discharges within or from the area.
- A county in which the unduplicated sum of: (i) the area that is federally designated urbanized area; (ii) the area delineated as a regulated coverage area; (iii) the jurisdiction of a regulated entity designated pursuant to Section 7 of this act; and (iv) the area that is regulated by a stormwater permit required pursuant to Section 8 of this act equals or exceeds 85% of the total geographic area of the county.

Coordination of Phase II and Other Stormwater Management Programs. –Section 3 provides that if there are conflicting or overlapping stormwater management requirements, the most stringent requirements will apply.

General Permit. – Section 4 directs DENR to develop and issue a Phase II NPDES general permit for stormwater management containing postconstruction stormwater management measures developed in accordance with Section 10 of the temporary Phase II stormwater management rule adopted by the EMC on October 10, 2002, as modified by this act. A local government may opt to be covered under the Phase II NPDES general permit for stormwater management developed by DENR rather than developing its own individual permit.

Delegation. – Section 5 provides that a public entity that does not administer a stormwater permit throughout the entirety of its planning jurisdiction and whose planning jurisdiction includes a regulated

coverage area may voluntarily undertake the implementation of a local stormwater management program approved by DENR.

Phase II Stormwater Implementation Deadlines. – Section 6 provides deadlines for when DENR must make certain permitting decisions. Section 6 also provides that:

- A public entity federally designated as a regulated entity will develop and implement postconstruction stormwater management measures within 24 months of the issuance of its stormwater permit.
- A public entity designated as a regulated entity pursuant to subdivisions (2)(the State designation process) and (3)(designation under a total maximum daily load (TMDL) implementation plan) of Section 7 of the act will develop and implement postconstruction stormwater management measures within 36 months of the issuance of its stormwater permit.

Designation. – Section 7 provides a detailed designation process by which the EMC may require additional local governments and other entities to obtain a stormwater permit.

Petition Process. – Section 8 provides a detailed petition process by which the EMC may require additional local governments and other entities to obtain a stormwater permit upon the petition of any person.

Model Ordinance. – Section 9 directs the EMC to develop a stormwater model ordinance to assist local governments and others in developing and implementing stormwater management programs and controls. In the development of the model ordinance, the EMC will provide for options that take into consideration differences among local governments in the State, including but not limited to population, financial resources, and human resources.

Design Manual. – Section 10 provides for the development of a stormwater design manual to assist local governments and others in determining which controls are best suited to their unique characteristics, including but not limited to hydrology, topography, climate, soils, and receiving waters.

Federal and State Development or Redevelopment Projects. – Section 11 provides that DENR will have exclusive jurisdiction to establish stormwater management requirements with respect to a particular project that is not under the jurisdiction of a federal or State agency that holds a Phase I or Phase II NPDES permit for stormwater management that applies to all of the agency's activities or that applies to the particular project.

Definitions. – Section 12 provides definitions for the act and its implementation.

Construction of Act. – Section 13 provides that:

- Nothing in the act shall be construed to alter the authority of the EMC or a local government with regard to stormwater management.
- The act shall not be construed to affect pending litigation.
- Except as specifically provided by the act, the act shall not be construed to give effect to any Phase II stormwater management rules that have not become effective as provided in the Administrative Procedure Act.
- The federal exemptions from NPDES permit requirements for agriculture and silviculture apply to this act.
- The act shall not be construed to affect any vested right to development under any provision of statutory or common law.
- The act shall not be construed to affect any delegation of power or duty to the EMC or DENR.

This act became effective August 2, 2004, and expires October 1, 2011. (GG, JH)

Phosphorus Nutrient Management/Animal Feedlots

S.L. 2004-176 (HB 1112), as amended by S.L. 2004-195, Sec. 1.9 (SB 823, Sec. 1.9), implements requirements applicable to National Pollution Discharge Elimination System (NPDES) permits and animal waste management plans governing animal feeding operations to make the State permit requirements consistent with federal regulations. The act:

- Amends the definition of "animal operation" to include agricultural feedlots with liquid animal waste management systems that discharge to surface waters.
- Requires owners and operators of animal operations to apply for a NPDES permit 180 days prior to construction of a new animal waste management system (System) or expansion of an

existing System and to obtain the NPDES permit prior to commencement of construction or expansion.

- Requires owners and operators of proposed new dry litter poultry facilities of a certain size to apply for NPDES permits 180 days prior to operation of a new System.
- Establishes deadlines for existing animal operations and dry litter facilities of a certain size to apply for NPDES permits.
- Requires that Systems be constructed and operated so that the animal operation the System serves does not result in a discharge except as may result because of rainfall from a storm event more severe than the 100-year, 24-hour storm.
- Requires certain dry litter poultry facilities to develop animal waste management plans and specifies the components of the plan.
- Provides that phosphorus shall be a rate-determining element for land application of animal waste if testing demonstrates the need to limit the application of phosphorus in order to comply with the nutrient management standard.
- Establishes a three-tier system of annual permit fees for dry litter poultry facilities. The annual fee will be $50.00, $150.00, or $300.00, depending on the size of the facility.
- Directs the Department of Environment and Natural Resources (DENR) to evaluate the need for and availability of information to identify poultry facilities that may be subject to regulation. DENR must report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission on or before January 1, 2005.

S.L. 2004-195, Sec. 1.9 (SB 823, Sec. 1.9) modified the effective date of Section 7 of S.L. 2004-176, which directs DENR to evaluate the information needs for the identification of poultry facilities that may be subject to regulation, thus the section became effective August 2, 2004. The remaining sections of S.L. 2004-176 become effective January 1, 2005. (JM, GG)

Miscellaneous

River Basins Advisory Commissions

S.L. 2004-83 (SB 859) establishes the Catawba/Wateree River Basin Advisory Commission and the Yadkin/Pee Dee River Basin Advisory Commission. Each commission will consist of 15 members from North Carolina and South Carolina. The commissions have no regulatory authority. The purpose of the commissions is to:

- Provide guidance and make recommendations to local, state, and federal legislative and administrative bodies on the use, stewardship, and enhancement of the water and other natural resources within the respective river basin.
- Provide a forum for discussion of issues affecting the river basin's water quality, water quantity, and natural resources.
- Promote communication, coordination, and education among stakeholders.
- Identify problems and recommend appropriate solutions.
- Undertake studies and publish reports related to water quantity, water quality, and other natural resources of the river basin.
- Determine the optimum approach to comprehensively and collaboratively provide recommendations for integrated river management.

This act is similar to legislation enacted by the General Assembly of South Carolina on July 6, 2004 (2004 South Carolina Laws Act 262).

This act became effective July 8, 2004. (JM)

Requirements for Animal Waste Management Systems Technical Specialists

S.L. 2004-124, Sec. 12.7C (HB 1414, Sec. 12.7C) provides that the requirements and qualifications for animal waste management systems technical specialists (technical specialists) shall not be changed and the scope of the work they are authorized to perform shall not be decreased before July 1,

2006. Technical specialists are approved by the Soil and Water Conservation Commission to provide various forms of assistance to farmers in the development and certification of their animal waste management plans.

This section became effective July 1, 2004. (TD)

Expand Express Review Pilot Program

S.L. 2004-124, Sec. 12.9 (HB 1414, Sec. 12.9) expands the geographic coverage of the Express Review Pilot Program (Program) that was established by S.L. 2003-284, Sec. 11.4A. Under the Program, the Department of Environment and Natural Resources (DENR) provides expedited review of certain environmental permits, approvals, and certifications and may charge fees higher than those set by statute for the normal review process. The Program may apply to permits, approvals, and certifications under the erosion and sedimentation control program, the coastal management program, and the water quality programs, and focuses on stormwater permits, stream origination certifications, water quality certifications, erosion and sedimentation control permits, and Coastal Area Management Act permits.

The original Program was implemented in the Wilmington and Raleigh Regional Offices of DENR. S.L. 2004-124, Sec. 12.9 (HB 1414, Sec. 12.9) directs DENR to expand the Program to two additional regional offices and authorizes DENR to establish additional positions to administer the Program. No later than March 1, 2005, DENR will report to the Fiscal Research Division and the Environmental Review Commission on the Program and whether it should be continued or expanded.

This section became effective July 1, 2004. (JH)

Expand One-Stop Permit Assistance Program Statewide

S.L. 2004-124, Sec. 12.12 (HB 1414, Sec. 12.12) expands statewide and makes permanent the one-stop environmental permit application assistance and tracking system pilot project established by S.L. 2000-67, Sec. 13.7. Under the expanded, permanent one-stop environmental permit application assistance and tracking system program (Program), the Department of Environment and Natural Resources (DENR) must provide each person who submits a complete application for a permit with a time frame within which the applicant may expect a final decision regarding the issuance or denial of the permit. Unless otherwise provided by law, when an applicant has provided DENR with all required information and documentation and DENR fails to issue or deny the permit within 60 days of the projected date for a final decision, the permit shall be automatically issued. The permit will not automatically issue if the applicant substantially amends an application or agrees to receive a final decision at a later date.

DENR shall track the time required to process each complete permit application that is subject to the Program, compare the actual and projected dates of final permit decisions, and identify each permit that was issued or denied more than 90 days after receipt of a complete application and document the reasons for the delayed action. No later than October 1 of each year, DENR shall report to the House of Representatives and the Senate Appropriations Subcommittees on Natural and Economic Resources, the Fiscal Research Division, and the Environmental Review Commission on this information and shall recommend permit time frames for all major permits it issues.

This section becomes effective January 1, 2005. (JH)

Monitoring and Emergency Cleanup Funds for Texfi Site Contamination

S.L. 2004-124, Sec. 12.14 (HB 1414, Sec. 12.14) authorizes the Department of Environment and Natural Resources (DENR) to use up to $50,000 of money appropriated to the Division of Waste Management of DENR for cost share of federal Superfund cleanup funds to monitor and perform emergency cleanup activities at the Texfi site in Cumberland County.

This section became effective July 1, 2004. (TD)

Amend Environmental Laws-3/Appointments

S.L. 2004-195 (SB 823) amends various environmental laws and makes other changes, including:

- Makes technical corrections to various laws related to the environment and natural resources.
- Modifies environmental reporting requirements.
- Abolishes the Watershed Protection Advisory Council and the Scientific Advisory Council on Water Resources and Coastal Fisheries Management.
- Extends by one year the time available to the Environmental Management Commission to develop and adopt permanent rules governing water conservation and water reuse during drought and emergency water situations.
- Provides for staggered terms of the members of the Agricultural Finance Authority, appoints members to the Authority, and limits future members of the Authority from serving more than three successive three-year terms.
- Prohibits the sale or dispensing of raw milk and raw milk products to anyone other than a permitted milk hauler or a milk processing facility.

This act became effective August 17, 2004.

Section 7 of this act provides that vacancies may be filled in certain offices during a holdover period. For additional information on this section, see **State Government**. (TD)

Wetlands Reimbursement/Local Tax Base

S.L. 2004-188 (SB 933) requires State and local government agencies that acquire land for wetlands mitigation in an enterprise tier one or tier two county to reimburse the county in which the land is located a sum equal to the estimated amount of property taxes that would have accrued to the county for the next 20 years. The requirement does not apply when the land purchased and the wetlands permitted to be lost are located in the same county.

This act became effective August 17, 2004. (CA)

Finance Vital Projects/Studies

S.L. 2004-179, Parts 2, 3, 4, and 8 (HB 1264, Parts 2, 3, 4, and 8) authorize the issuance of special indebtedness (certificates of participation, or "COPs") for the financing of parks projects and clean water projects, including various capital projects, and for the financing of natural heritage projects. The act sets a cap on the maximum principal amount of special indebtedness that may be incurred of $45,000,000, $20,000,000 of which may be incurred for land near military bases, and $25,000,000 of which may be incurred for parks and gamelands. Up to $32,000,000 (of the total $45,000,000) in special indebtedness may be issued before July 1, 2005. Repayment of the debt for these purposes would be made from existing revenue streams dedicated to the Parks and Recreation Trust Fund, the Natural Heritage Trust Fund, and the Clean Water Management Trust Fund. The act requires that the Parks and Recreation Authority allocate funds from the Parks and Recreation Trust Fund with a geographic distribution across the State to the extent practicable. The act states that it is the intent of the General Assembly that the purposes for which parks, heritage, and clean water indebtedness may be incurred include, as a high priority, acquiring land near military bases to prevent encroachment. The act further provides that none of the parks, heritage, and clean water debt proceeds may be used to acquire property by eminent domain.

These parts became effective August 5, 2004.

Parts 5 and 7 of this act create the Debt Affordability Advisory Committee and authorize the State Treasurer to study the use of innovative public financing tools. For additional information on this section, see **Finance**.

Part 6 of this act authorizes the University of North Carolina and the State Board of Community Colleges to study the mission and education program needs for the University System and the Community College System. For additional information on this section, see **Education**. (JM)

Studies

Legislative Research Commission

Light Pollution and Conservation Studies

S.L. 2004-161, Secs. 2.1(1)c and 2.1(9)c (SB 1152, Secs. 2.1(1)c and 2.1(9)c) authorize the Legislative Research Commission to study:

- Light pollution.
- Soil and water conservation issues.

These sections became effective August 2, 2004. (TD)

New/Independent Studies/Commissions

Saltwater Fishing Fund

S.L. 2004-187, Secs. 12(c) and 12(d) (HB 831, Secs. 12(c) and 12(d)) direct the Board of Trustees of the North Carolina Saltwater Fishing Fund to study issues related to the establishment of a unified recreational fishing license for recreational fishing in both the inland and coastal fishing waters of the State. The Board shall make specific findings as to whether a unified licensing system should be adopted for recreational fishing in the State and, if so, what the system should be and how it should be implemented. The Board shall submit the results of this study to the Joint Legislative Commission on Seafood and Aquaculture no later than April 15, 2005.

These sections became effective August 17, 2004. (JH)

Referrals to Existing Commissions/Committees

Coastal Resources Commission

New Urban Waterfront Development Pilot

S.L. 2004-117 (SB 732) directs the Coastal Resources Commission (CRC) to implement a pilot under which one county may designate an area as a new urban waterfront (NUW area), and allows for the development of a NUW area as provided in the act. A NUW area as defined by the act is an area designated for development that includes a mixture of residential and commercial uses, recreational areas, and facilities for governmental or other civic purposes; provides for pedestrian access to residential, commercial, civic and recreational areas; and incorporates open space for recreational and other public purposes.

Section 4 of the act directs the CRC to evaluate the impacts on water quality and other environmental impacts from the NUW area, and the costs and benefits from the development, in order to determine whether additional developments within NUW areas should be allowed, and whether rules governing the developments should be modified. The CRC is directed to annually report its interim findings and recommendations to the Environmental Review Commission beginning October 1, 2005, and to report its final findings and recommendations no later than October 1, 2010.

This act became effective July 17, 2004. (JM)

Commission for Health Services

Innovative Peat-Based Wastewater Systems Study

S.L. 2004-161, Part VIII (SB 1152, Part VIII) directs the Commission for Health Services (Commission) to evaluate whether to implement a pilot program testing innovative septic systems that utilize peat-based technology. The Commission will identify two or more counties that would participate in the pilot program as part of the evaluation. The Commission will report the results of its evaluation to the Senate and House of Representatives Appropriations Subcommittees on Natural and Economic Resources, the Fiscal Research Division, and the Environmental Review Commission on or before January 15, 2005.

This part became effective August 2, 2004. (TD)

Environmental Review Commission

Leaking Petroleum Underground Storage Tank Cleanup Funds Solvency

S.L. 2004-124, Sec. 30.10(f) (HB 1414, Sec. 30.10(f)) directs the Environmental Review Commission (ERC) and the Joint Legislative Transportation Oversight Committee to jointly study the role of the State and the Department of Environment and Natural Resources in implementing the Leaking Petroleum Underground Storage Tank (UST) Cleanup Program. The issues to be considered include:

- The role of the State in assisting owners and operators of USTs in meeting applicable financial responsibility requirements and the availability and adequacy of private insurance.
- The adequacy of current and projected future revenue into the Commercial Leaking Petroleum UST Cleanup Fund and the Noncommercial Leaking Petroleum UST Cleanup Fund (UST Funds).
- The feasibility and desirability of privatizing some or all of the functions of the UST Funds.
- The State's role in the cleanup of orphan UST sites.
- Whether existing UST rules are adequate to prevent future releases from USTs.

The ERC and the Joint Legislative Transportation Oversight Committee are to report the results of their study, including any legislative proposals, to the General Assembly no later than January 31, 2005.

This section became effective July 1, 2004. (TD, GG)

Environmental Review Commission Studies

S.L. 2004-161, Part XIX (SB 1152, Part XIX) directs the Environmental Review Commission (ERC) to study:

- Whether the State should modify the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle.
- Whether the State should modify the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle.

The ERC shall consider whether these modifications should be made on a revenue neutral basis or should be made so as to generate additional revenue to be used to fund initiatives designed to improve air quality and the efficiency of the State's transportation system.

Part XIX also authorizes the ERC to study:

- The overall effectiveness of the State's efforts to protect the environment and conserve the natural resources of North Carolina.
- Whether information compiled by the Statewide Floodplain Mapping Unit would be useful and relevant to dam operators, local agencies, and State agencies with regard to making decisions about coordinating and controlling water releases from dams, flood control, floodplain management, and emergency evacuation procedures.

- Water restriction guidelines created by the Department of Environment and Natural Resources and implemented by local governments.
- Various approaches to prevent and reduce stormwater pollution throughout the State.
- Other topics:
  - Development and funding of regional water supply systems.
  - Establishing a Clean Air Trust Fund.
  - Revocation of contracts under certain circumstances.
  - The feasibility of encouraging permeable surfaces as a deterrent to stormwater runoff.
  - Ways to protect a property owner whose land is adjacent to or downstream from a site on which alterations of the existing flow of stormwater will occur.

This part became effective August 2, 2004. (TD)

Joint Legislative Commission on Seafood and Aquaculture

Study Taking of Shrimp with Trawl Nets in Certain Inland Waters

S.L. 2004-161, Part XXV (SB 1152, Part XXV) authorizes the Joint Legislative Commission on Seafood and Aquaculture to study whether it should be unlawful to take shrimp with trawl nets in certain inland waters. The Commission may report the results of its findings, with any recommended legislation, to the 2005 General Assembly.

This part became effective August 2, 2004. (JH)

Joint Legislative Growth Strategies Oversight Committee

Joint Legislative Growth Strategies Oversight Committee

S.L. 2004-161, Part III (SB 1152, Part III) provides that the Joint Legislative Growth Strategies Oversight Committee may study the following issues:

- Delegating authority to cities and counties;
- Modernizing city and county planning; and
- Transferable development rights.

The provision amends the Committee's expiration and reporting requirements contained in Section 3.3 of S.L. 2001-491. The change extends the Joint Legislative Growth Strategies Oversight Committee's expiration date and reporting requirements to January 16, 2007.

This section became effective August 2, 2004. (JHM)

Marine Fisheries Commission

Amend Shellfish Laws

S.L. 2004-150, Secs. 6 and 7 (HB 1427, Secs. 6 and 7) authorize the Marine Fisheries Commission (MFC) to study:

- Whether and how to establish a process by which shellfish cultivation leases that have been terminated may be leased without reverting to public bottom.
- Issues related to corporate ownership of shellfish cultivation leases.

If the MFC undertakes either study, the MFC shall report its findings and recommendations to the Joint Legislative Commission on Seafood and Aquaculture no later than December 1, 2004.

These sections became effective August 2, 2004. (JH)

Referrals to Departments, Agencies, Etc.

State Parks System Additions & Study

S.L. 2004-24, Sec. 2 (HB 1574, Sec. 2) directs the Division of Parks and Recreation (Division) of the Department of Environment and Natural Resources to study the feasibility and desirability of acquiring land and establishing a new State recreation area at Blewett Falls Lake, including estimation of the cost of developing the proposed recreation area. The Division must report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission on or before December 1, 2005.

This section became effective June 25, 2004. (JM)

Twenty-Four Hour Access to Fort Fisher State Recreation Area During the Fall and Winter/Funds for Department Study/Activities at Fort Fisher

S.L. 2004-124, Secs. 12.3(b) and 12.3(c) (HB 1414, Secs. 12.3(b) and 12.3(c)) direct the Department of Environment and Natural Resources (DENR) to conduct a study of vehicle use at Fort Fisher State Recreation Area (Fort Fisher) including consideration of:

- The demand for vehicle access to the beach during different times of the year;
- The impact of vehicles on sea turtles and nesting birds;
- The sea turtle and bird nesting activity at Fort Fisher as compared with the nesting activity on the adjoining beach managed by the Bald Head Conservancy and on Masonboro Island; and
- The economic impact of restricting 24-hour vehicle access to the beach.

DENR must report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission by February 1, 2005. The section also provides that of the funds appropriated to DENR for the 2004-2005 fiscal year, $25,000 shall be used to conduct the study and for other educational, conservation, and enforcement activities at Fort Fisher.

These sections became effective July 1, 2004. (JM)

Phosphorous Nutrient Management/Animal Feedlots

S.L. 2004-176, Sec. 7 (HB 1112, Sec. 7), as amended by S.L. 2004-195, Sec. 1.9 (SB 823, Sec. 1.9), directs the Department of Environment and Natural Resources (DENR) to evaluate the need for and availability of information to identify poultry facilities that may be subject to regulation. DENR must report its findings and recommendations, including any legislative proposals, to the Environmental Review Commission on or before January 1, 2005.

S.L. 2004-195, Sec. 1.9 (SB 823, Sec. 1.9) modifies the effective date of this act, therefore, this provision became effective August 2, 2004. (JM)

Stream Mapping

S.L. 2004-161, Part XXXIII (SB 1152, Part XXXIII) directs the Geographic Information Coordinating Council and the Department of Environment and Natural Resources to develop and recommend a plan to improve the mapping and digital representation of surface waters in North Carolina, including intermittent and perennial streams, lakes, and ponds, to the General Assembly and the Environmental Review Commission on January 15, 2005.

This part became effective August 2, 2004. (TD)

Office of State Personnel Study – DENR Parks and Recreation Law Enforcement Officers

S.L. 2004-161, Part XLII (SB 1152, Part XLII) directs the Office of State Personnel to conduct a reclassification study of all sworn law enforcement officers employed in the Division of Parks and Recreation of the Department of Environment and Natural Resources. The Office of State Personnel is directed to report the results of this study to the General Assembly and the Fiscal Research Division of the General Assembly by January 3, 2005.

This part became effective August 2, 2004. (TM)

Summary of Funding for Environmental Initiatives
2004 Legislative Session

	FY 2004-05	
Total Funding for Environmental Initiatives	**$3,274,387**	
Environmental Permitting	**$200,000**	
Express Permitting Pilot Program: Expand to two additional regions	100,000	NR
One-Stop Permitting Program: Expand state-wide	100,000	
Environmental Health	**$50,000**	
Shellfish Sanitation Program	50,000	
Waste Management	**$1,000,000**	
Superfund Cost Share Matching Funds	1,000,000	NR
Water Resources	**$263,777**	
River Basin Water Supply Initiative	150,000	
	33,254	NR
Water Resources Projects Environmental Engineer	80,523	
Natural Resource Programs	**$1,760,610**	
Forest Resources positions	105,101	
Forest Resources equipment	15,000	NR
Recreational Fishing License funds	750,000	NR
Center City Park (Greensboro)	500,000	NR
Soil and Water Regional Coordinator	41,749	
Additional Grassroots Science Museum funding	296,000	
Additional Partnership for the Sounds funding	52,760	

Prepared by Fiscal Research Division, October 2004

Studies to be Conducted by the Environmental Review Commission

Organized by topics: air quality, coastal issues, environmental health, fishing, general, hazardous substances, land quality, parks and conservation, solid waste, water quality, water quantity, wetlands

air quality

ERC	Report To/ Authority	Report Due
Shall study whether the State should modify the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle (Sen. Clodfelter)	2005 General Assembly S.L. 2004-161, sec. 19.10(1)	upon convening
Shall study whether the State should modify the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle (Sen. Clodfelter)	2005 General Assembly S.L. 2004-161, sec. 19.10(2)	upon convening
May study establishment of Clean Air Trust Fund	2005 General Assembly S.L. 2004-161, sec. 19.6	upon convening

general

ERC	Report To/ Authority	Report Due
May study the overall effectiveness of State's efforts to protect the environment and conserve the natural resources of NC.	2005 General Assembly S.L. 2004-161, sec. 19.2	upon convening
May study the development of a plan to Share Floodplain Mapping Information (Rep. Daughtridge)	2005 General Assembly S.L. 2004-161, sec. 19.3	upon convening
May study issues related to the fair bargain act - study the revocation of contracts under certain circumstances (Sen. Horton)	2005 General Assembly S.L. 2004-161, sec. 19.7	upon convening

water quality - general

ERC	Report To/ Authority	Report Due
May study various approaches to prevent and reduce stormwater pollution throughout the State, including but not limited to: low impact design as a stormwater management technique; financial and regulatory incentives; ...(Rep. Gibson)	2005 General Assembly S.L. 2004-161, sec. 19.11	upon convening
May study the feasibility of encouraging permeable surfaces as a deterrent to stormwater runoff (Sen. Horton)	2005 General Assembly S.L. 2004-161, sec. 19.8	upon convening
May study ways to protect a property owner whose land is adjacent to or downstream from a site on which alterations of the existing flow of stormwater will occur (Sen. Rucho)	2005 General Assembly S.L. 2004-161, sec. 19.9	upon convening

* "oral" indicates oral report was given to ERC or S+A; "mail" indicates the report was mailed to members; "in" indicates that the report has been received but not yet distributed.

water quality - ground

ERC	Report To/ Authority	Report Due
May study issues related to the LUST program, including any of the following: 1) the adequacy of program funding; 2)Options for management of available funds, including prioritization and preapproval; 3) changes in deductible and copayment reqs., etc.	General Assembly SL 2003-352, Sec. 12	2004 Regular Session or 2005 General Assembly

ERC and the Joint Legislative Transportation Oversight Committ	Report To/ Authority	Report Due
Shall study the role of the State and DENR in implementing the Leaking Petroleum Underground Storage Tank (UST) Cleanup Program. Several direct areas of focus listed in act.	General Assembly S.L. 2004-124, Sec. 30.10.(f)	31 Jan 2005

water quantity

ERC	Report To/ Authority	Report Due
May study water restriction guidelines created by the DENR and implemented by local governments, including an evaluation of economic impacts and recommendations for establishing consistency (Rep. Gibson)	2005 General Assembly S.L. 2004-161, sec. 19.4	upon convening
May study the issue of the development and funding of regional water supply systems (Sen. Shaw)	2005 General Assembly S.L. 2004-161, sec. 19.5	upon convening

* "oral" indicates oral report was given to ERC or S+A; "mail" indicates the report was mailed to members; "in" indicates that the report has been received but not yet distributed.

Status of Reports to the ERC Required by Law

Organized by topics: air quality, coastal issues, environmental health, fishing, general, hazardous substances, land quality, parks and conservation, solid waste, water quality, water quantity, wetlands

air quality

DAQ	Report To/ Authority	Report Due	Status*
Study issues related to monitoring emissions of mercury and the development and implementation of standards and plans to implement programs to evaluate available control technologies; shall estimate the benefits and costs of alternative strategies to	EMC, ERC S.L. 2002-4, Section 12	Annually (Interim 1 Sep 2003) (Findings 1 Sep 2005)	Sep 03 distrib 2/24/04 Sep 04 in
Study issues related to the development and implementation of standards and plans to implement programs to control emissions of carbon dioxide (CO2) from coal-fired generating units and other stationary sources; evaluate available control technologies and	EMC, ERC S.L. 2002-4, Section 13	Annually (Interim 1 Sep 2003) (Findings 1 Sep 2005)	Sep 03 distrib 2/24/04 Sep 04 in

EXECUTIVE SUMMARY

The Department of Environment and Natural Resources prepares an annual report on the status of leaking petroleum underground storage tanks.

North Carolina's underground storage tank program is administered by the Division of Waste Management's UST Section within DENR. The section enforces UST regulations and manages funds used to perform cleanups of petroleum UST discharges or releases. The program was initiated in 1988 in response to growing reports of USTs leaking petroleum into soil and drinking water supplies. Funding for the program has been provided by the Commercial and Noncommercial Trust Funds, the Groundwater Protection Loan Fund, the Federal UST Regulatory Grant and the Federal Leaking UST Fund.

For the period July 1, 2003 through June 30, 2004

Commercial Fund Revenues	$26,934,685
Commercial Fund Total Expenditures	$26,041,631
Noncommercial Fund Revenues	$ 8,060,151*
Noncommercial Fund Total Expenditures	$ 9,001,443
Petroleum UST Incidents – Reported	1650
Petroleum UST Incidents - Closed	1345

* Includes transfer of $2,036,932 motor fuel and kerosene tax from commercial to noncommercial trust fund.

For the entire UST program period of July 1, 1988 until June 30, 2004

Commercial Fund Revenues	$373,785,729
Commercial Fund Total Expenditures	$370,677,394
Noncommercial Fund Revenues	$ 81,409,726
Noncommercial Fund Total Expenditures	$ 79,776,706
Petroleum UST Incidents - Reported	18,146
Petroleum UST Incidents - Closed Out	9,336

The status of the Commercial and Noncommercial Funds as of June 30, 2004

Commercial Fund Balance	$ 3,077,997
Commercial Fund Claims Pending	$30,522,435
Noncommercial Fund Balance	$ 1,635,015
Noncommercial Fund Claims Pending	$ 5,646,580

The initiation of expedited claim reviews beginning May 2001 contributed to an increase in payments from the Commercial Fund. A significant backlog of pending claims was processed

and, as a result, reimbursements nearly doubled during the six-month period between July 1, 2001 and December 31, 2001. Beginning in June 2002, a decision to make reimbursements from the Commercial Fund only when funds became available was implemented. This resulted in a significant backlog of claims with payments pending in the Commercial Trust Fund. For the 12-month period from July 1, 2003 through June 30, 2004 claims paid, both for the Commercial and Noncommercial funds, decreased relative to the previous fiscal year. This is due primarily for the following reasons: more cost-effective corrective actions being implemented, a continued delay in completing reimbursements for the Commercial Fund which began back in 2002, and a transfer to the Noncommercial Fund of $2,036,932 in accordance with NCGS 119-18(b).

The Noncommercial Fund is not currently able to meet all obligations based on the current rate of claims submitted. Claims pending exceed the Noncommercial balance for the second year in a row since the inception of the Fund.

PURPOSE OF THE UNDERGROUND STORAGE TANK REGULATORY PROGRAM AND THE COMMERCIAL AND THE NONCOMMERCIAL TRUST FUNDS

The purpose of the UST regulatory program is to:

(1) Set standards for the installation and operation of commercial petroleum underground storage tanks. These technical standards are designed to prevent the accidental release of petroleum products into the environment and to provide early notice of any leaks that do occur;

(2) Insure that steps are taken to correct UST systems that are improperly installed, improperly operated, or malfunctioning; and

(3) Provide oversight for assessment and cleanup of soil and groundwater contamination caused by leaking UST systems.

NOTE: The State does not regulate the installation and operation of noncommercial underground storage tanks (such as home heating oil tanks).

The purpose of the Commercial UST Trust Fund is to help the owners of commercial UST systems meet a federal requirement that they demonstrate sufficient financial responsibility to pay for assessment and cleanup of petroleum releases from their UST systems. The UST owner must also demonstrate the ability to pay any claim by a third party for bodily injury or property damages resulting from a petroleum release (such as contamination of a drinking water well). By paying most of the costs of assessment, cleanup and damages related to leaking USTs, the Commercial Trust Fund provides the required financial assurance and relieves the tank owner of the need to demonstrate financial responsibility in some other way -- through the purchase of private environmental insurance or the posting of a bond, for example.

The purpose of the Noncommercial UST Trust Fund is to assist owners and operators of those UST systems (primarily home heating oil tanks) in paying for assessment and cleanup of petroleum releases from those tanks.

B & B Mini Mart, 4869 Highway 421 North, Vilas, NC 28692, Incident Number 23895

In January 2002, Watauga County Emergency Management personnel responded to a resident complaining of petroleum odors inside his home. The smell was determined to be coming from gasoline in the soil beneath the home and the source of the gasoline traced to a leaking underground storage tank (UST) system at a convenience store/gasoline station across the highway from the residence.

The leaking UST contaminated six drinking water wells and a small creek with benzene, toluene, xylene, MTBE, and other gasoline constituents. Accumulated vapors from the petroleum-contaminated groundwater caused the state toxicologist to order the evacuation of one home while the home was ventilated. It took almost one year of ventilation before benzene levels in

the home were low enough for the evacuated residents to safely return to the house. Bottled water, well water filtering systems, and new wells were provided for the residents of the four homes affected. No municipal or county water lines are available in the area.

DENR's investigation revealed that the soil beneath the convenience store/gasoline station was severely contaminated and the plume of contaminated groundwater extended over 1000 feet downgradient of the leaking UST system. Three UST systems were removed from the site and a fourth system closed in place before remediation began. Aggressive steps were taken to remove grossly contaminated groundwater, free product on the groundwater and soil vapors. Remediation did not remove all groundwater contamination. The final steps in remediation involve removal of contaminated soil followed by monitoring. After the tank owners paid the $20,000 deductible amount, the Commercial Trust Fund reimbursed an additional $256,202. Another claim for $147,349 has been submitted, which included third-party costs of $80,079. We have no projections for final costs at this time.

UST SYSTEMS IN NORTH CAROLINA

Active and temporarily closed USTs as of 31 Dec 2003

Regulated Petroleum USTs:	30,758
Regulated Hazardous Substance USTs:	242
Commercial Heating Oil USTs:	2,627
Total USTs:	33,627

Active and temporarily closed USTs paying tank fees as of 30 April 2004

USTs over 3,500 gallons capacity:	26,191
USTs less than or equal to 3,500 gallon capacity:	5,863
Total USTs paying tank fees:	32,054

Note: USTs owned by the federal government, hazardous substance tanks, and tanks not in use after 12/22/88 do not pay tank fees.

UST Construction

Steel tanks:	16,895
Fiberglass Reinforced Plastic (FRP):	8,279
Steel/FRP:	5,826
Single Wall Tanks:	30,193
Double Wall Tanks:	807

UST Owners

There are 4860 UST owners with 2 or less facilities who own 5163 facilities which contain 12,770 USTs.

There are 572 owners with more than 2 facilities who own 6813 facilities which contain 20,857 USTs.

UST Age

Install Dates	Active USTs	Temp Closed USTs	Total USTs	% of Total
Before 1973	3609	1361	4970	16
1974 to 1983	6101	604	6705	22
1984 to 1993	12399	261	12660	41
1994 to 2004	6637	28	6665	21

RISK CLASSIFICATION OF DISCHARGES AND RELEASES FROM UST SYSTEMS

North Carolina Administrative Code Title 15A, Subchapter 2L, Section .0115 directs DENR to classify the risk of each known discharge or release as high, intermediate, or low. Basically, state rules classify the discharge based on immediate threat to public health or the environment. The classification scheme was designed to be used in deciding the level of cleanup required as well as the immediacy of the need for cleanup
Generally, a **High Risk** release is one that directly threatens public health or the environment and must be responded to immediately. Some examples of high risk releases are those that have contaminated a water supply well or have created an explosion hazard from petroleum vapors.

An **Intermediate Risk** release is one that has contaminated or threatens to contaminate surface water, is located in a wellhead protection area or an area that provides recharge to drinking water aquifers, or where the contamination concentrations are more than 1000 times levels allowed under State groundwater standards or federal drinking water standards. Intermediate risk releases generally do not represent immediate threats as compared to high risk releases that have already contaminated drinking water wells. However, intermediate risk releases have the potential to endanger public health and the environment if not addressed. At many intermediate risk releases, action must be taken quickly to prevent contamination from increasing in concentration and in area.

Low Risk releases are those that do not meet the criteria for "high risk" or "intermediate risk" releases or are ones which pose no significant risk to human health or the environment. Generally, low risk releases are those that require some cleanup to make the property completely safe for any use, but do not require immediate action. Low risk releases may have significant levels of contamination; the difference is that the contamination does not, at the time of classification, have the potential to reach wells or surface waters. It is important to remember that the risk classification represents a snapshot of conditions at the time of the assessment. Low risk releases can quickly become high risk releases if conditions change. For example, if a water

supply well is installed near a low risk release with contaminated ground water, the risk classification would change to high risk.

Some releases are classified as **Unconfirmed Risks** because, at the time of risk classification, there is insufficient data available to quantify the risk. Generally, unconfirmed risk releases are those which are newly reported or those for which the assessments are not complete.

Corner Pantry 600 Howard Gap Road, Hendersonville, NC Incident Number 28103

In April 2003, an environmental assessment of the Corner Pantry (for a real estate transaction) detected soil contaminated with gasoline constituents. The UST system owner began an investigation to find the source of the gasoline release. Several months later, a homeowner drilled a new well on his property about 700 feet from the Corner Pantry and discovered that the well water had a peculiar odor. When the well water was tested, it was found to contain MTBE and traces of gasoline constituents. The source of the contamination was traced back to the Corner Pantry. The UST Section continued sampling other water supply wells in the area, finding high levels of MTBE. Investigation revealed that the plume of contaminated groundwater extended over 1000 feet to the south and southwest of the Corner Pantry.

The actual source of the gasoline release has not yet been fully determined, but on-site investigation confirmed that the release is not continuing. The contamination may be from an old leak that went undetected for a period of time. The Hendersonville area has fractured bedrock fairly close to the surface and the contamination has moved into these fractures. To date, approximately 60 water supply wells have been sampled and tested. Many of the wells have been contaminated; the water supply for several hundred people has been affected. Sampling and testing of wells is continuing.

At the first sign of contaminated drinking water supplies, alternative sources of water--bottled water, filter systems, or temporary hookups to unaffected wells--were provided to those affected. The long term plan is to extend water lines from Hendersonville to connect affected water users to the Hendersonville water system. Cleanup of the contamination will involve remediation systems that vaporize petroleum constituents in the groundwater and in the soil. After the tank owner paid the $20,000 deductible amount, the Commercial Trust Fund reimbursed the tank owner an additional $24,158. Another $187,045 in claims, primarily for water line extension, have been submitted. At this time, final costs are unknown but are projected to exceed $1 million.

PETROLEUM UST INCIDENTS

Discharges or releases from petroleum USTs are reported to DENR regional offices where they are added to an incident management database. Table 1 lists the number of incidents reported and closed in each region during the twelve-month period from July 1, 2003 through June 30, 2004, as well as the number of incidents reported and closed since the UST program began in 1988. Table 1 also shows that there are 9311 active incidents. In addition, there have been 6086 UST systems closures where no discharges or releases were reported or where the releases were

below action levels. These UST closures are not technically "incidents" but are tracked as "clean closures."

Beginning Jan. 2, 1998, the UST Section implemented risk-based corrective action rules for petroleum UST incidents. Discharges or releases under these rules receive a risk classification of "high," "intermediate," or "low" based on the potential threat to human health and the environment. Of the total number of UST incidents closed since 1988, 63 percent were closed following implementation of Risk-Based Corrective Action. The total number of active incidents has generally increased since 1988; however, recent data indicates the trend may be leveling off (see Figure 1, page 6).

TRENDS IN REGULATED UST RELEASES AND CLAIMS AGAINST THE COMMERCIAL TRUST FUND

1. We track reported releases only, which we must assume are all releases.

2. The federal and state UST programs began in 1988. The rules required all USTs installed after December 1988 to have leak detection, financial responsibility, and an assessment at tank closure. They further required that all existing USTs be upgraded to those standards by December 1993.

   The increase in reported releases from 1988 until 1993 may have resulted from (1) the start up and initial growth of the UST consulting industry; (2) the closure of many USTs as owners decided they could not or would not bring their existing USTs up to standards; and (3) the legislated decrease in the deductible amount from $50,000 to $20,000 for 1992 and 1993.

3. After 1994, the number of yearly reported releases decreased, but not down to present year levels. This decrease may have been the result of the end of the 1993 upgrade deadline. The remaining releases may have been the result of USTs being modified, assessed, and closed in response to additional federal and state rules which required all UST systems to have corrosion protection and spill and overfill prevention by December 1998.

4. After 1999, the number of reported releases decreased to the present level of 200 to 400 per year. This decrease may be the result of the effect of the end of the regulatory upgrades of 1993 and 1998. All USTs should now be upgraded to the required standards, so all reported releases after 1999 should be either from upgraded tank systems or from old releases that are just now being discovered. In addition, in 1997, the trust fund balance dropped significantly and the reimbursement waiting time began to increase. The decrease in reported releases after 1999 may also be partially the result of the consulting community marketing their services to non-regulated tanks since the noncommercial trust fund remained viable and reimbursements were much faster.

5. Presently, the number of reported releases from regulated USTs continues to show a slowly decreasing trend. We should be seeing releases only from upgraded tank systems or from old releases that are only now being discovered. However, there are a significant number of older tank systems in North Carolina and, as these USTs continue to age, we expect the leak rate to increase. About 16% of the tank systems are over 30 years old, and an additional 22 % are over 20 years old. In addition, further upgrade requirements, such as secondary containment of existing UST systems, could cause a resurgence of release reporting, as construction is performed on tank systems and "old" releases are discovered.

TRENDS IN NONREGULATED UST RELEASES AND CLAIMS AGAINST THE NONCOMMERCIAL TRUST FUND

1. We know of and track only reported releases and reported "clean" closures from unregulated USTs. Since inspections and registration of unregulated tanks are not required, and we do not know the number of such tanks in existence, we are unsure if these numbers accurately reflect unregulated tank activity.

2. Since the inception of the program in 1988, we have seen a general increase in the number of reported releases. This increase can be attributed to (1) start up of the UST consulting industry; (2) an increase in the environmental awareness of home buyers and lenders; and (3) conversion of home heating systems from oil to gas. In addition, in the last several years, we have seen an upswing in the marketing of consulting services. Some of this marketing may be due to the fact that, during this same time period, the commercial trust fund balance dropped significantly and the reimbursement waiting time began to increase, and the consulting community began marketing their services to non-regulated tanks since the noncommercial trust fund remained viable and reimbursements were much faster.

3. We expect this increasing trend in the number of reported releases from nonregulated USTs to continue and to be driven primarily by property transfers and marketing.

FUNDING FOR THE UNDERGROUND STORAGE TANK PROGRAM

Program funding is provided by revenues from the Commercial and Noncommercial Trust Funds and the Groundwater Protection Loan Fund. The Federal UST Regulatory Grant and the Federal Leaking UST Fund are provided by the Environmental Protection Agency. Of the 94 staff positions assigned to the UST program, state revenue funds 63 positions and 31 are supported by federal grants. In addition, the trust funds and federal grant pay for one laboratory position and four regional administrative positions which support the program.

Commercial and Noncommercial Trust Funds

The Leaking Petroleum Underground Storage Tank Cleanup Act of 1988* established two separate funds: the Commercial Trust Fund and the Noncommercial Trust Fund. Both may be used to reimburse eligible UST owners, operators and landowners for reasonable and necessary costs incurred as a result of environmental cleanup and third party liability claims. Additionally, both funds enable UST Section staff to:

- record and track UST release incidents;
- register and permit commercial USTs, manage a database and receive annual UST operating fee payments;
- identify responsible parties;
- provide technical assistance to tank owners and operators;
- inspect USTs to ensure compliance with UST regulations;
- monitor site cleanups;
- review site assessments and corrective action plans;
- evaluate innovative assessment and cleanup technologies;
- review reimbursement claim procedures;
- manage contracts for cleanups designated as "State Lead";
- inspect and monitor land applications of contaminated soil; and
- identify and evaluate abandoned petroleum USTs.

The UST Section has the authority to contract for the cleanup of petroleum UST incidents if the owner or operator cannot be identified or located, if the owner or operator is financially unable to perform cleanup or if the owner or operator refuses to perform the required cleanup. In the latter case, the section is authorized by general statute to recover costs incurred during assessment and cleanup activities.

Sources of funding for the Commercial Trust Fund include:

- a motor fuel and kerosene inspection tax,
- an excise tax (0.297 cents per gallon) on motor fuel and kerosene sales,
- annual payment of UST operating fees,
- costs recovered from UST owners and operators for State Lead sites,
- loan collection and interest for the Groundwater Protection Loan Fund, and
- interest earned on the account.

* General Statute 143-215.94A et.seq.

Owners and operators are required to pay annual operating fees to receive operating permits and to be eligible for the Commercial Fund. Annual fees for commercial USTs began at a rate of $30 for tanks with a capacity equal to or less than 3,500 gallons (small tanks) and $60 for tanks with a capacity in excess of 3,500 gallons (large tanks). Tank fees increased annually from 1989 to 1993. From 1993 to 1997, fees were $150 for small tanks and $225 for large tanks. Beginning Jan. 1, 1997, annual fees were increased to $200 for commercial USTs with a capacity equal to or less than 3,500 gallons and $300 for commercial USTs with capacity in excess of 3,500 gallons. Revenues received for the Commercial Fund for the twelve-month period from July 1, 2003 to June 30, 2004 were approximately $27 million (Table 3). The relative contributions to the Commercial Fund from each of the funding sources are illustrated in Figure 2.

Table 3 - Commercial Trust Fund Revenues
7/1/03- 6/30/04

Motor Fuel & Kerosene Inspection Tax	$ 2,562,662
Motor Fuel & Kerosene Excise Tax	$ 15,622,250

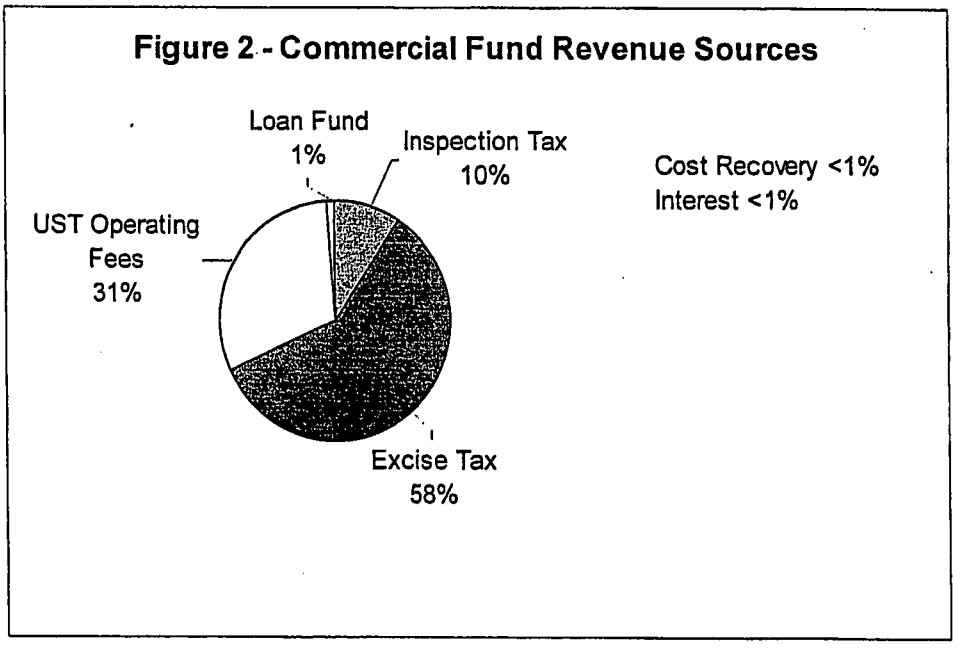
State Lead Cost Recovery	$ 86,592
Interest	$ 88,817
Loan Fund Collection and Interest	$ 264,556
Total Commercial Revenues	**$ 26,934,685**
Transfers to Noncommercial	$ (2,036,932)
Net Commercial Revenues	**$ 24,897,752**

Figure 2 - Commercial Fund Revenue Sources



Funding for the Noncommercial Trust Fund is provided by a motor fuel and kerosene inspection tax and excise taxes (0.047 cents per gallon) on kerosene and motor fuel sales.[1] Owners and operators of noncommercial USTs are not required to pay annual operating fees. Revenues

received for the Noncommercial Fund for the 12-month period from July 1, 2003 to June 30, 2004 were approximately $8 million (Table 4).

[1] House Bill # 681 of 1993

Motor Fuel & Kerosene Excise Tax	$ 3,496,240
Interest	$ 58,279
Transfer from Commercial Fund	$ 2,036,932
Cost Recovery	$ 505
Total Noncommercial Revenues	**$ 8,060,151**

Groundwater Protection Loan Fund

The Groundwater Protection Loan Fund Program was created in 1991.* It provided financial assistance to owners of commercial USTs who replaced or upgraded their tanks to meet the performance standards required for all USTs by Dec. 22, 1998. Administrative rules implementing the program were adopted by DENR and became effective Dec. 1, 1992. Revenues for the fund were generated through a 0.0025 cent (one quarter of one cent) per gallon motor fuel excise tax received from Jan. 1, 1992 through Dec. 31, 1994.

*Session Laws 1991, c. 538, s. 25 - G.S. 143-215.94P

Federal UST Regulatory Grant Program

This program promotes compliance with UST regulations. It provides the state's UST Section with $186,675 per year to fund three positions in the DWM central office. The positions provide technical assistance to the owners and operators of USTs, develop materials, conduct educational activities, train regional staff and conduct UST inspections.

Federal Leaking UST Fund

The Federal Leaking UST Trust Fund is used to clean up petroleum contamination from leaking USTs, provide potable water to affected third-parties, perform emergency activities, relocate residents affected by leaking USTs and conduct enforcement activities. This fund is limited to USTs regulated by federal agencies, primarily commercial tanks used for storing motor fuels. Tanks used for heating oil and those used for farm or residential uses (1,100 gallons capacity or less) are not covered by this fund.

Individuals (i.e., owners/operators) do not have access to the fund. Only the federal government and states with cooperative agreements with the EPA can draw on the fund. It may be used in situations when: (1) the responsible party cannot be identified; (2) the responsible party is

financially unable to pay for the cleanup; or (3) the responsible party is unwilling and refuses to undertake assessment and/or cleanup actions.

Since the state's UST program began in 1988, the Federal Leaking UST Fund has made 20 awards totaling $40,216,813 to the state's UST Section. As of June 30, 2004, the state spent $37,845,194 from these awards. Of this amount, $17,609,555 was spent for cleanup-related activities and $617,220 for enforcement actions. Administrative, operating, travel and equipment costs totaled $16,618,415.

The program is obligated to seek recovery of all costs incurred during state lead cleanups. As of June 30, 2004, the UST Section had recovered $1,625,358 in federal cleanup money through cost recovery actions. Of this amount, $801,209 came from the North Carolina Commercial Fund for sites determined eligible for Commercial Fund coverage after cleanup activities had begun. Cost recovery funds totaling $1,527,135 were returned to the Federal Trust Fund to be used for additional corrective action expenditures.

The EPA approved $1,957,081 for North Carolina from the Leaking UST Fund for FY 2003-2004.

RECEIPTS AND DISBURSEMENTS: COMMERCIAL AND NONCOMMERCIAL TRUST FUNDS AND GROUNDWATER PROTECTION LOAN FUND

Commercial and Noncommercial Funds

UST owners, operators and landowners may submit reimbursement claims for reasonable and necessary costs incurred during environmental assessment and cleanup activities. Claims may be submitted if the eligibility requirements for the trust funds are met. Deductibles that must be met before receiving reimbursement from the Commercial Fund range from $20,000 to $75,000. Noncommercial Fund deductibles are $0 for UST owners and operators, and $5,000 for landowners. Table 5 lists the receipts and disbursements by fiscal year for both funds for the period July 1, 1988 to June 30, 2004.

FY 97-98	2,530,036	667,724
FY 98-99	2,567,668	620,574
FY 99-00	2,579,540*	570,738
FY 00-01	2,730,236	733,811
FY 01-02	2,397,264	913,755
FY 02-03	2,221,851	1,166,494
FY 03-04	2,527,451	1,244,864
TOTAL	**$ 25,728,469**	**$10,731,236**

Incorporating the administrative costs into receipts and cleanup disbursements yields these Commercial and Noncommercial Fund balances:

Commercial Fund Balance (as of June 30, 2004)	**$ 3,077,997**
Noncommercial Fund Balance (as of June 30, 2004)	**$ 1,635,015**

* Adjustment due to a transfer of $288,117 from the Commercial Fund to the Federal Trust Fund as a cleanup expenditure rather than an administrative cost.

Groundwater Protection Loan Fund

After the Groundwater Protection Loan Fund was created, 11 North Carolina banks agreed to administer the loan program. As of June 30, 1995, four loans totaling $1,228,350 had been closed. After this date, remaining funds of $31,288,889 were deposited into the Commercial Trust Fund. Loan repayments are also deposited into the Commercial Fund. During the twelve-month period ending June 30, 2004, $249,047 was repaid. Total receipts for the Loan Fund since its inception in January 1992 are $33,036,751.

CLAIMS AGAINST THE CLEANUP FUNDS

Claims against both the Commercial and Noncommercial Funds are processed on a "first-come, first-served" basis. The status of all claims requesting reimbursement from both funds that were received as of June 30, 2004 is presented in Table 7. These claims only include costs claimed to date, and do not represent the total costs for cleanups.

UST Section staff have supervised contract cleanups at 308 commercial and noncommercial sites (Table 7, 241 commercial and 67 noncommercial). Currently, DENR has four contracts with environmental engineering/geology firms that perform a range of assessment and cleanup actions. The term of these contracts is 18 months with an option to renew for an additional 18 months.

Table 7 - Claims Against the Cleanup Funds
7/1/88 - 6/30/04

	Commercial Fund		Noncommercial Fund	
	Number	Cost	Number	Cost
Claims Paid	21,915	$338,698,495	8,090	$ 67,625,873
Incidents Denied Totally [1]	33	$ 4,573,040	4	$ 59,845
Claims Denied Partially [2]	13,250	$ 70,826,206	3,812	$ 9,598,853
Total Deductibles Paid	-------	$ 66,445,056	-------	$ 390,090
Claims Pending	2,219	$ 30,522,435	548	$ 5,646,580
Contracted Cleanups [3]	289	$ 9,940,930	77	$ 2,460,050

[1] Ineligible
[2] Excessive or undocumented costs
[3] State Lead actions undertaken or completed

COMMERCIAL AND NONCOMMERCIAL FUND BALANCES AND PROJECTED NEEDS

Commercial Fund

As of June 30, 2004, the Commercial Fund balance was $3,077,997 with pending claims of $30,522,435 (see Figure 3, Page 14). Since Jan. 1, 2002, the difference between the fund balance and the pending amount has continued to increase (see Figure 4, Page 14). During the six-month period from July 1, 2001 to Dec. 31, 2001, expedited reviews were initiated in an effort to reduce claim review time. While the claim review time has been reduced, the result has been a delay in issuance of the reimbursement checks, since the Commercial Fund can only pay out what has been received for the month. Claim amounts continue to increase as well as the backlog of claims awaiting payment. Revenues, however, remain steady.

Figure 3 - Commercial Fund Balance and Claims Pending

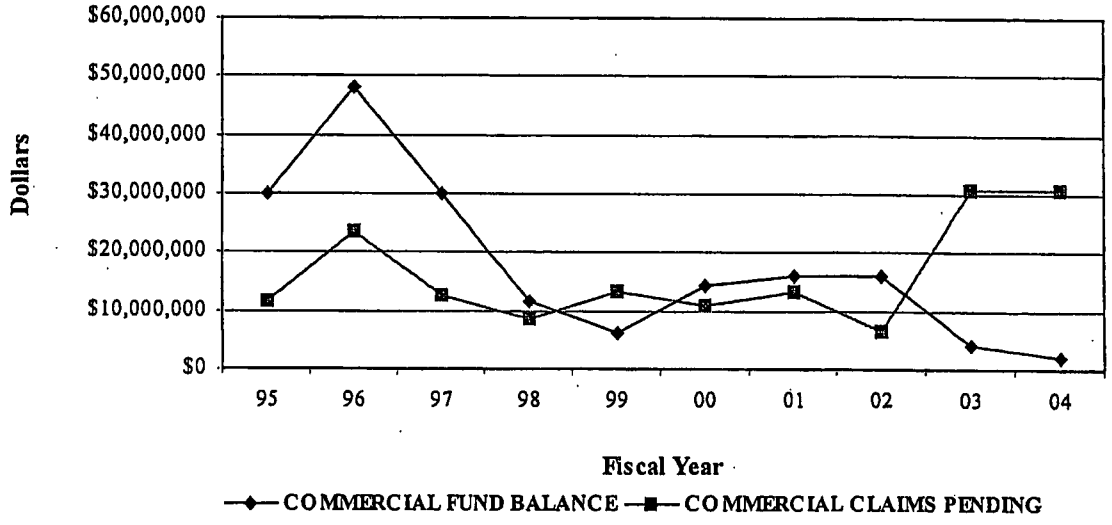

Figure 4 - Commercial Fund Balance Minus Claims Pending

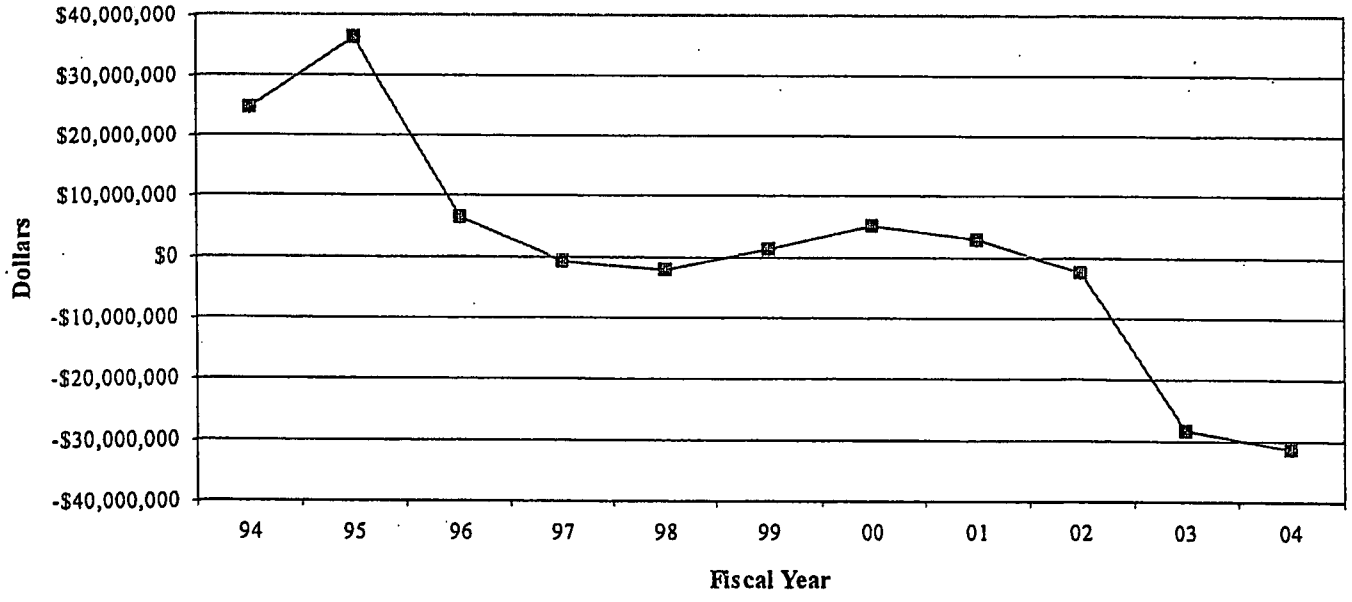

Table 8 - Total Commercial Fund Revenues and Expenditures
7/1/03 – 6/30/04

Total Commercial Revenues (see Table 3, page 14)	**$26,934,685**
Total Claims and Contracted Cleanups	$23,514,179
Administrative Costs	$ 2,527,451
Total Commercial Expenditures	**$26,041,630**

One initiative which may affect a future demand on the Commercial Fund is pay-for-performance based cleanups. On Oct. 1, 2001, the General Assembly ratified House Bill 1063, which allows responsible parties to participate in the pay-for-performance program on a voluntary basis. Pay-for-performance is a reimbursement method that requires cleanup goals to be met before payments can be made to environmental consultants. This reimbursement method requires the Trust Fund to obligate the contracted cleanup costs. Pay-for-performance obligations may initially place a higher demand on the Trust Fund, but should greatly decrease the costs of cleanups and thus result in a lesser burden to the Trust Fund.

Another factor that may effect future demands on the Commercial Fund is third-party claims. There are currently several pending third-party claims under review which have the potential to place a burden of many hundreds of thousands of dollars on the Commercial Fund. Other third party claims may be planned that have not yet been submitted for review.

After UST operating fees were raised on Jan. 1, 1997, revenue from this funding source declined through the end of FY 1998-99 (see Table 9). This decrease was likely due to the reduction in the number of registered USTs that occurred as a result of the federal 1998 upgrade regulations. The number of registered USTs continued to increased during the period from July 1, 2003 to June 30, 2004. However, UST operating fees have remained essentially stable.

Table 9 - Commercial UST Population and Operating Fee Revenue

Fiscal Year	No. of Commercial USTs Billed	Operating Fee Revenue
FY 1996-97	37,776	$ 10,839,975
FY 1997-98	36,563	$ 10,008,917
FY 1998-99	34,428	$ 8,697,468
FY 1999-00	33,558	$ 8,844,093
FY 2000-01	33,776	$ 8,464,019
FY 2001-02	32,839	$ 8,553,715
FY 2002-03	31,155	$ 8,087,033
FY 2003-04	32,005	$ 8,309,807

At present, approximately 7,488 commercial incidents have yet to be closed out. With minor work performed in accordance with the risk based rules, many of these sites may receive "no further action" letters. However, some will require additional assessment and corrective action, that will subsequently result in additional demands on the Commercial Fund.

Data tracking improvements are continuosly made to the UST incident management database. These changes will enable the UST Section to better predict the number of incident closures and project Commercial Fund expenditures.

UST systems pose a substantial threat to human health and the environment. On average, over 1,200 leaks are reported each year. Maintaining the quality of North Carolina's drinking water depends on preventing releases to the environment. Direct education and technical assistance for tank owners and operators is critical. Only education and assistance ensure responsible handling of petroleum products, including methyl tertiary-butyl ether, and early detection in the event of a leak.

North Carolina currently has about 31,956 active regulated USTs at 10,836 facilities. We estimate that 40 to 50 percent of the facilities are located within 500 feet of both domestic and public drinking water supplies. Our inspection data show that over 30 percent of tank owners and operators do not comply with UST regulations. These regulations cover proper operation and maintenance, with an emphasis on leak detection. If we are to preserve the quality of North Carolina's drinking water, improving compliance must be a future priority.

Noncommercial Fund

As of June 30, 2004, the Noncommercial Fund balance was $1,635,015. The total for pending claims stood at $5,646,580. Based on the past 12 month period, it appears that demands on the Fund will increase. We anticipate this will result in delayed claim payments, just as the Commercial Fund was affected (see Figure 5). Similar to the Commercial Fund, the difference between the fund balance and the pending amount has continued to increase (Figure 6). For FY 2003-2004, Table 10 shows a summary of the noncommercial revenue versus the expenditures.

Figure 5 – Noncommercial Fund Balance and Claims Pending

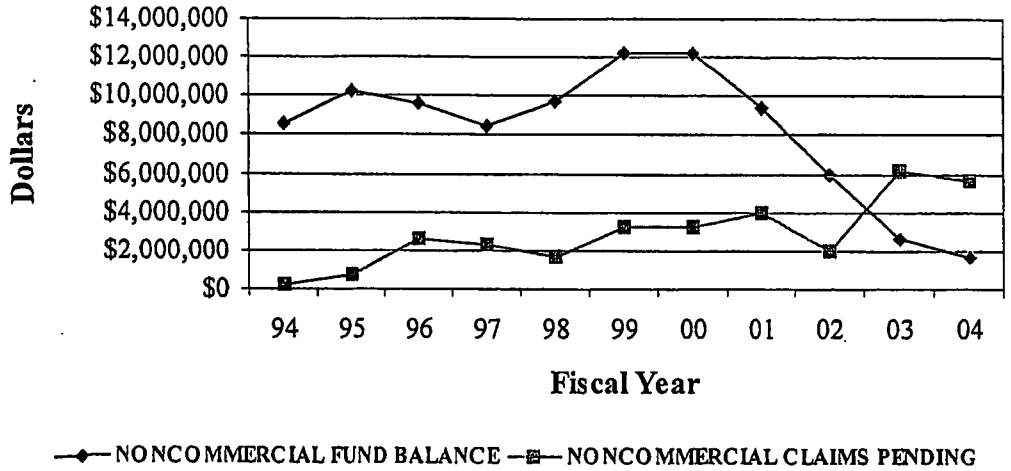

Figure 6 – Noncommercial Fund Balance Minus Claims Pending

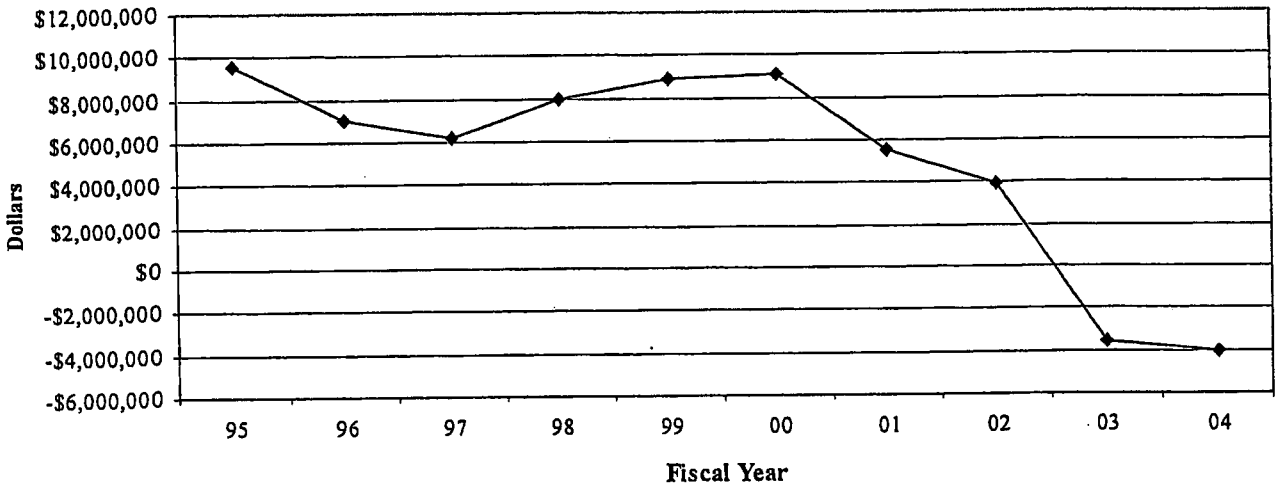

Table 10 – Total Noncommercial Fund Revenues and Expenditures

7/1/03-6/30/04

Total Noncommercial Revenues (see Table 2, page 3)	**$ 8,060,151**
Total Claims and Contracted Cleanups	$ 7,756,579
Administrative Costs	$ 1,244,864
Total Noncommercial Expenditures	**$ 9,001,443**

Table 11 shows the estimated cost to complete cleanups for noncommercial incidents reported from July 1, 2003 to June 30, 2004. It should be noted, however, that cleanups can easily extend over several years and costs may vary greatly. In addition, these figures do not include remedial costs for reported releases from past fiscal years.

Table 11 - Estimate of Cleanup Costs for Noncommercial Incidents
Reported July 1, 2003 - June 30, 2004

Region	Incidents*	Total Estimated Cleanup Cost**
Asheville	44	$ 1,086,800
Fayetteville	25	$ 617,500
Mooresville	82	$ 2,025,400
Raleigh	131	$ 3,235,700
Washington	77	$ 1,901,900
Wilmington	45	$ 1,111,500
Winston-Salem	104	$ 2,568,800
Total	**508**	**$12,547,600**

* Calculations of the last twelve-month period indicate that approximately 56 percent of reported new releases are from noncommercial sites.

** An average cost of $24,700 is used as an estimate of total cleanup costs for noncommercial sites.

PAY FOR PERFORMANCE

On Oct. 15, 2001, House Bill 1063 was enacted by the North Carolina General Assembly. This bill gives the Division of Waste Management's Underground Storage Tank program the authority to allow performance-based cleanups of sites where petroleum has been discharged or released from underground storage tanks. Sites selected for the pilot program will be posted for competitive bidding in the North Carolina Interactive Purchasing System. A performance-based contract will be awarded to the qualified environmental services firm that submits the lowest, technically qualified bid for an acceptable remedial proposal for the advertised site. A series of milestones (generally percentage reductions in contaminate levels in the soil and groundwater) must be achieved before payments are made to the cleanup firm from the Commercial or Non-Commercial Fund.

On Nov. 2, 2001, the Division of Waste Management convened a stakeholders workgroup consisting of representatives of the Professional Engineers of North Carolina, the Consulting Engineers Council of North Carolina, the North Carolina Board for the Licensing of Geologists and the North Carolina Petroleum Marketer's Association to develop a temporary rule. A follow-up meeting on Nov. 9, 2001 resulted in the further refinement of the rule and the discussions of the contract and bidding procedures proposed for use with the rule.

The proposed temporary rule was presented to the Groundwater Committee of the Environmental Management Commission on Dec. 12, 2001 and received a favorable vote to proceed to full commission review in February 2002. On Feb. 14, 2002, the EMC voted to approve the publication of the temporary rule in the North Carolina Register. The temporary rule was published for public comment between March 15 and April 15, 2002 in Volume 16, Issue 18, p. 2019 of the NC Register. No comments were received. The Commission adopted the temporary rule on May 14, 2002. On July 11, 2002 the Commission voted to allow the Division of Waste Management to proceed with permanent rule making and to publish the permanent rule in the NC Register. The permanent ruke was made effective on July 1, 2004 and published in the July 2004 Issue of the NC Register.

In July of 2003, House Bill 897 was passed that allowed $2.5 million from the Commercial Fund and $250,000 from the Non-Commercial Fund to be allocated for the Pay-For-Performance Program in each fiscal year. At this time, there are five sites, two Federal-Lead and three responsible party lead sites awaiting finalization of the PFP contract language. Currently, the contract language is being reviewed by the Attorney General's Office. Pending approval, UST staff will meet with representatives of the Purchase and Services Division and the Department of Administration to finalize the PFP contract submittal procedure. Once completed, the five sites will be sampled to provide a current picture of the contamination levels remaining and then the contracts will be placed in the Interactive Purchasing System for awarding.

RECOMMENDATIONS

Based on the results of this report, the UST Section makes the following recommendations for the Commercial and Noncommercial Trust Funds:

- Additional revenue should be made available for expedited payment of Commercial Fund and Noncommercial Fund claims.

- Responsible parties of UST releases should continue to be encouraged to consider pay-for-performance cleanups at their sites. Pay-for-performance is a reimbursement method that requires cleanup goals to be met before payments can be made to environmental consultants. PFP programs in other states have dramatically reduced the costs for cleanups. Costs are down 66 percent in Florida and 50 percent in South Carolina. PFP also accelerates the rate of cleanups. The Department of Environment and Natural Resources will monitor the obligated costs for pay-for-performance contracts and the potential cleanup cost savings of the PFP program.

- Establish a statute of limitations for filing claims. Because fund deductable amounts vary, we propose grouping all years with like deductables (Example: releases detected 6/88-12/91 and 1/92-12/93) and assigning a common claim submittal deadline. The UST section can inform its customers of the new deadline, and then provide one year for all claims to be prepared and filed. By learning more about the outstanding claims, the UST Section can increase its ability to predict future expenditures.

- Consider private insurance as the FR mechanism for new installations and phase in existing USTs.

Notice of Planning Meeting
Coastal Site Visits
Schedule of Future Meetings
Meetings of Interested Parties (605 Working Groups)
Additional Information

COMMISSION MEETING:

The Environmental Review Commission (ERC) will meet jointly with the Joint Legislative Commission on Seafood and Aquaculture (JLCSA) at 11:00 a.m. Thursday 18 November 2004 in Room 544 of the Legislative Office Building in Raleigh. The meeting will focus on the development and implementation of the Coastal Habitat Protection Plan pursuant to G.S. 143B-279.8 and a discussion of issues regarding the implementation of the coastal recreational fishing license established by S.L. 2004-187 (Saltwater Fishing Fund). **We anticipate that the meeting will last until late afternoon. Boxed lunches will be provided for members of the ERC and JLCSA.**

The ERC will meet for its regular monthly business meeting at 9:30 a.m. Friday 19 November 2004 in Room 544 of the Legislative Office Building in Raleigh. At this meeting, the ERC will begin or continue studies for which the ERC is responsible, hear reports from State agencies, discuss topics to be considered at future meetings, and attend to other matters. Listed below are potential agenda topics for this meeting and for future meetings. More specific information regarding the agenda for the 19 November meeting of the ERC will be developed at the staff planning meeting discussed below. **We anticipate that the meeting will last until early to mid afternoon. Boxed lunches will be provided for members of the ERC.**

STUDY TOPICS:

Air Quality:

1) Modification of the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle (S.L. 2004-161, Sec. 19.10(1))

2) Modification of the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle (S.L. 2004-161, Sec. 19.10(2))

3) Issues related to greenhouse gas emissions and global climate change

Miscellaneous:

4) Effectiveness of the State's efforts to protect the environment and conserve the natural resources of NC (S.L. 2004-161, sec. 19.2)

5) Development of a plan to share floodplain mapping information (S.L. 2004-161, Sec. 19.3)

6) Efforts to stimulate renewable energy production in the State

7) Results of the conservation needs assessment conducted by the Land for Tomorrow Coalition

Water Quality:

8) Approaches to prevent and reduce stormwater pollution throughout the State (S.L. 2004-161, Sec. 19.11)

9) Issues related to the Leaking Petroleum Underground Storage Tank (UST) Cleanup Program (S.L. 2003-352, Sec. 12)

10) The role of the State and DENR in implementing the Leaking UST Cleanup Program (S.L. 2004-124, Sec. 30.10.(f)) (joint study with the Joint Legislative Transportation Oversight Committee)

11) Identification and closure of inactive or abandoned animal waste management lagoons

Water Quantity:

12) Water restriction guidelines created by DENR and implemented by local governments, including an evaluation of economic impacts and recommendations for establishing consistency across the State with respect to classes of water use (S.L. 2004-161, Sec. 19.4)

13) Development and funding of regional water supply systems (S.L. 2004-161, Sec. 19.5)

14) Water conservation measures being implemented in the State and incentive programs and other voluntary programs that can help foster water conservation and reuse

15) Expansion of the guaranteed energy savings contracts program for governmental units to include contracts that provide for the conservation of water and sewer usage

REPORT TOPICS:

Air Quality:

16) Annual report on the cost of the Title V Program (G.S. 143-215.3A(c)

17) Annual report on implementation of S.L. 2002-4 (Clean Smokestacks Act) (S.L. 2002-4, Sec. 14)

18) Annual report on issues related to the development and implementation of standards and plans to implement programs to control emissions of mercury and carbon dioxide from coal-fired generating units and other stationary sources of air pollution (S.L. 2002-4, Sec. 12-13)

19) Annual report on increasing the use of alternative-fueled and low-emissions light-duty cars and trucks in privately owned fleets (G.S. 143-215.107C(c))

20) Annual report on development and implementation of a plan to reduce vehicle miles traveled by private sector employees and vehicle emissions resulting from job-related travel, including commuting to and from work (G.S. 143-215.107C(e))

21) Annual report on development and implementation of a plan to reduce vehicle miles traveled by State employees and vehicle emissions resulting from job-related travel, including commuting to and from work (S.L. 1999-328(4.6))

22) Annual report on promotion of telework/telecommuting for State employees and achieving the goal of reducing State employee vehicle miles traveled in commuting by 20% without reducing total work hours or productivity (S.L. 1999-328(4.8))

23) Report on the evaluation and adjustment of the boundaries of the area served by each Metropolitan Planning Organization (G.S. 136-202(d))

Parks and Recreation / Land Conservation:

24) Parks and Recreation Trust Fund Annual Report, Fiscal Year 2003-2004 (G.S. 113-44.15(c))

25) North Carolina Natural Heritage Trust Fund Award Report, Fiscal Year 2003-2004 (G.S. 113-77.9(e))

26) Annual report on progress towards attaining the State's goal of protecting one million acres of farmland, open space, and conservation lands (G.S. 113A-241(c))

27) Annual report on implementation of the Conservation Easements Program and inventory of all conservation easements held by DENR (G.S. 113A-235(c))

Water Quality:

28) Annual report on the Wastewater Discharge Elimination Program (S.L. 2001-452, Sec. 2.9)

Water Quantity:

29) Annual report on the progress of water supply planning (G.S. 143-355(n))

Wetlands:

30) Implementation of the Wetlands Restoration Program and use of funds in the Wetlands Restoration Fund (G.S. 143-214.13)

PLANNING MEETING:

To facilitate development of the agenda for the 19 November meeting of the ERC, to plan for subsequent meetings of the ERC, and to receive input from interested persons regarding the work of the ERC, the Commission Counsel will hold an informal planning meeting at **10:00 a.m. on Tuesday 9 November 2004 in Room 605 of the Legislative Office Building**. Persons who wish to participate in the development of the agenda for meetings of the ERC, or who are interested in any matter before the ERC, are invited to attend.

COASTAL SITE VISITS:

Members and staff of the ERC and JLCSA will visit several coastal sites in the Atlantic Beach/Morehead City/Beaufort area related to marine fisheries beginning at 9:00 a.m. on Monday 29 November 2004. These site visits will be similar to those originally scheduled for 27 September 2004 but were subsequently canceled because of Hurricane Jeanne. No business meeting will be held in conjunction with the 29 November 2004 site visits. Members should, however, plan to arrive in Atlantic Beach by 5:00 p.m. Sunday 28 November 2004 if possible. Further information on the site visits, including information on accommodations, will be sent to members of the ERC and the JLCSA in the next week.

SCHEDULE OF FUTURE MEETINGS:

The ERC will not meet on 22, 23, or 30 November, so it is no longer necessary to ask that you reserve these dates. Below is a schedule of meetings of the ERC for December 2004 through January 2005. This schedule is tentative and subject to adjustment. For planning purposes, please reserve these dates.

Commission Meeting	Staff Planning Meeting
Tuesday 7 December 2004	Wednesday 1 December 2004
Wednesday 12 January 2005	Wednesday 5 January 2005
Thursday 13 January 2005	
Thursday 20 January 2005	
Tuesday 25 January 2005	

MEETINGS OF INTERESTED PARTIES (605 WORKING GROUPS):

The Commission Counsel will hold meetings of interested parties on specific topics as indicated below:

Limit Liability for Environmental Cleanups Working Group (HB 1603/SB 1222)
10:00 a.m. Thursday 2 December 2004 – 605 Legislative Office Building

ADDITIONAL INFORMATION:

If you have questions related to the Commission, please feel free to contact the Commission Counsel or other Commission staff at (919) 733-2578.

General Assembly of North Carolina

Joint Legislative Commission on Seafood and Aquaculture
and
Environmental Review Commission

Agenda

11:00 a.m. Thursday, November 18, 2004
Room 544 Legislative Office Building

1. Call to order
   Senator Charles W. Albertson, presiding

2. Introductory remarks by Co-chairs
   Senator Charles W. Albertson
   Senator Daniel G. Clodfelter
   Representative Pryor A. Gibson
   Representative Daniel F. McComas
   Representative Bonner L. Stiller
   Representative William L. Wainwright

3. Report to the Commission and explanation of agenda items
   George F. Givens, Commission Counsel

4. Report on progress in developing and implementing the Coastal Habitat Protection Plan; opportunity to review and comment on the Plan (G.S. 143B-279.8)
   Michael W. Street, Chief
   Habitat Protection Section, Division of Marine Fisheries, DENR

WORKING LUNCH – Estimated for 12:00 p.m. to 1:00 p.m. (Lunch Provided)

Robin W. Smith, Assistant Secretary for Planning and Policy
DENR

5. Discussion of issues regarding the implementation of the coastal recreational fishing license established by S.L. 2004-187 (Saltwater Fishing Fund)
   Jeff W. Hudson, Commission Counsel

   Preston P. Pate, Director
   Division of Marine Fisheries, DENR

   Richard B. Hamilton, Executive Director
   Wildlife Resources Commission

   Daniel J. Whittle, Senior Attorney
   North Carolina Regional Office, Environmental Defense

   Michael G. Ward, President
   Coastal Conservation Association of North Carolina

   Benjamin "Mac" Currin, Member
   Marine Fisheries Commission

   Ron McPherson, Coordinator
   1999 Coastal Recreational Fishing License Survey

   Additional Comment

6. Discussion and announcements

7. Adjourn

NAME	FIRM OR STATE AGENCY	TELEPHONE

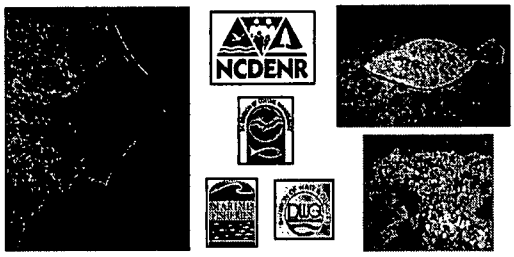
North Carolina Coastal Habitat Protection Plan

November 2004



Eastern North Carolina's Economy

- Tourism
- Retirement
- Commercial fishing
- Recreational fishing
- Agriculture
- Forestry

- All are based on a healthy and productive environment

History

- CHPP builds on earlier studies
  - Albemarle-Pamlico Estuarine Study: 1994
  - Coastal Futures Committee Report: 1994
  - Blue Ribbon Advisory Council on Oysters: 1995
  - Fisheries Moratorium Steering Committee: 1996
  - Estuarine Shoreline Stakeholders Report: 1999
- All cited land use, stormwater runoff, habitat loss, fishing gear effects as majors issues affecting coastal habitat
- Limited implementation success

Coastal Habitat Protection Plans

- DENR program; CHPPs drafted by DMF staff
- Initial CHPP to be adopted by EMC, CRC, MFC by December 31, 204
  - Implementation plans January – June 2005
  - Begin implementation July 2005
- Technical oversight by CHPP Team (DMF, DCM, DWQ, DEH, WRC)
- Policy oversight by Intercommission Review Committee (IRC – two members each from CRC, EMC, MFC)
- ***THREE COMMISSIONS MUST COOPERATE***

Coastal Habitat Protection Plan goal

"...long-term enhancement of coastal fisheries associated with each habitat" (G.S. 143B-279.8)

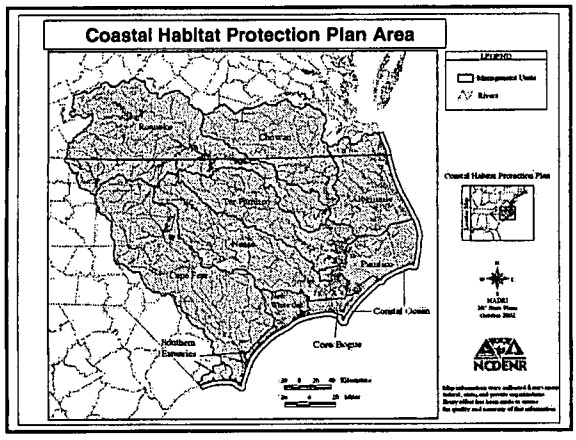
CHPP Requirements

[G.S. 143B-279.8.]

- **Describe and classify biological systems in the habitat**
- **Evaluate the function, value to coastal fisheries, and trends in habitat**
- **Identify existing and potential threats to the habitat and impact on coastal fishing**
- **Recommend actions to protect and restore the habitats**

CHPP and Science

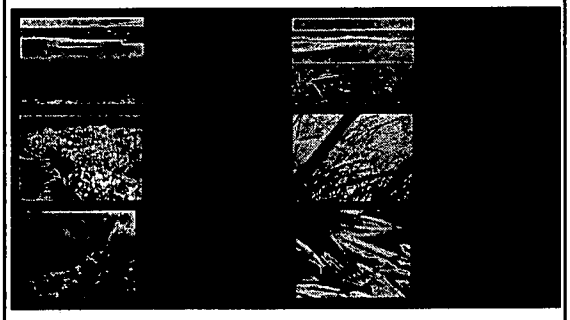
- CHPP is a scientific document
- Began drafting 1999
- > 50 scientists met to provide guidance in February 2000. Many continued to contribute information.
- Drafts reviewed and edited by dozens of scientists
- Reviewed by Intercommission Review Committee (Two members each from EMC, CRC, MFC)



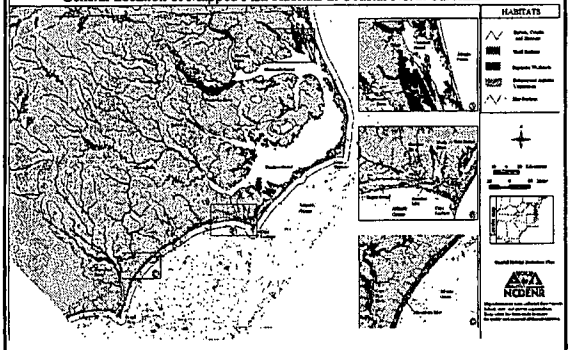
Fish Habitat Defined

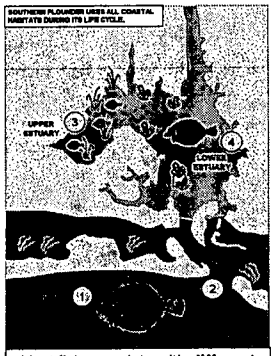
Freshwater, estuarine and marine areas that support any of the various life stages of commercial and recreationally important fish species, as well as those forage species important in the food chain

Six Interdependent Fish Habitats Support North Carolina's Coastal Fisheries



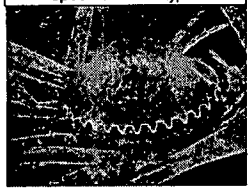
General Location of Mapped Fish Habitats in Coastal North Carolina





Most fish associate with **different habitats** at different life stages

Some fish depend strongly on **specific** habitat types

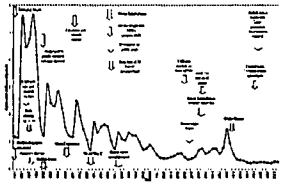


Because habitats are interdependent, all fish depend on the **total habitat system**

Loss and Degradation of Shell Bottom

The Evidence

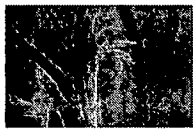
- Subtidal oyster reefs in Pamlico Sound system
  - Major losses due to oyster dredging late 1880s – early 1900s
  - Some displacement downstream due to flow and salinity changes and losses from harvesting, dredging, poor water quality
  - Not returning to previous levels [disease, bottom-disturbing fishing, greatly reduced cultch (surface for attachment)]
- Intertidal reefs more stable in southern coast.
- Partially mapped during 1880s and late 1980s to present



Loss and Degradation of SAV

The Evidence

- Most SAV mapped during late 1980s and early 1990s
- Anecdotal records suggest significant decline (> 50%) of low-salinity SAV in western Pamlico Sound and tributaries since the 1970s
- High salinity grasses fairly stable (Outer Banks – Bogue Sound)
- Water clarity is key factor for SAV survival
- Sediment and nutrients in water column reduce water clarity
- Some recovery in Chowan and other areas since 1980s as discharges removed and BMPs implemented

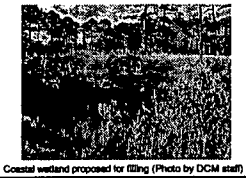


Loss and Degradation of Wetlands

The Evidence

- Coastal wetlands mapped
  - Hydric soil maps - 1950s
  - Wetland types - 1994
- Estimated 50% loss since pre-colonial times
- Most wetlands losses occurred prior to 1970s
- Current rate of loss has greatly slowed due to regulation

Cleared and ditched 404 wetland (Photo by DWQ staff)



Coastal wetland proposed for filling (Photo by DCM staff)

Water Quality Degradation
The Evidence

Nationwide Trends

- EPA report (2002) indicated that > 30% of U.S. rivers and 50% of estuaries and lakes are too polluted for swimming or fish consumption.
- Numerous studies show correlation between increasing human population and water quality degradation; which is a challenge given population growth on the coast, and in river basins that flow to coast.

North Carolina Trends

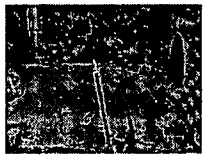
- According to land cover data, between 1982 and 1997, urban/built-up land and roads increased in coastal river basins by 43-132%

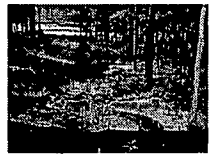
Corolla, NC

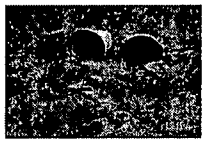
Water Quality Degradation
The Evidence

Impaired waters, increasing shellfish harvest closures, and fish kills indicate that significant water quality problems exist in North Carolina.

Sedimentation from Land Disturbing Activities

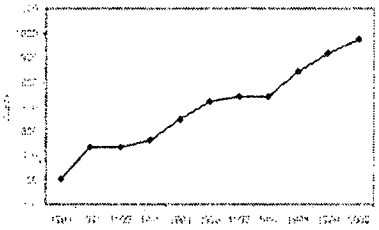






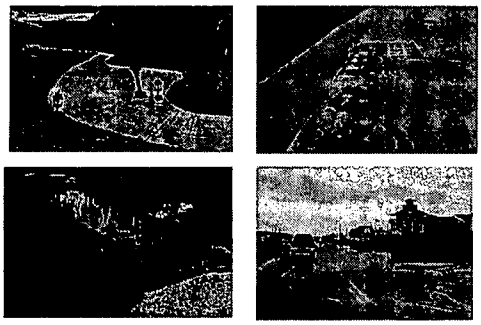
Water Quality Degradation
The Evidence

Shellfish Harvest Closures in Outstanding Resource Waters

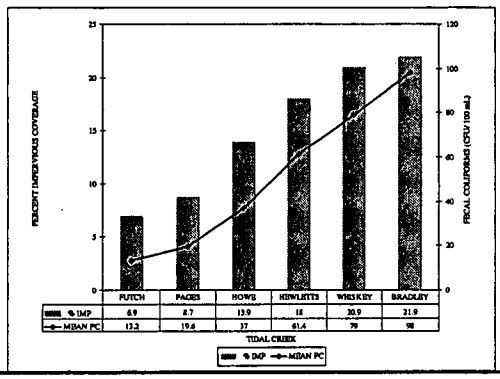


Data Source: Shellfish closure areas from DEH Shellfish Sanitation and Recreational Water Quality Section

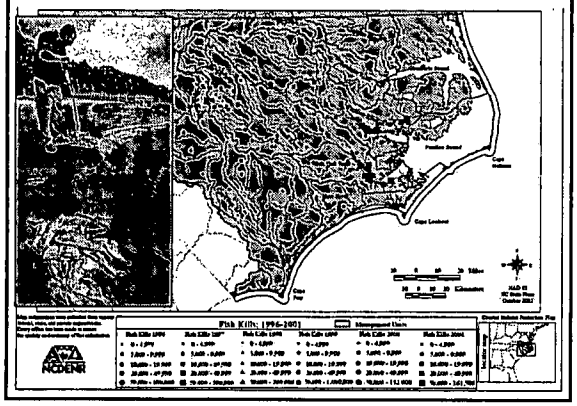
Runoff from Impervious Surfaces
(Mostly from urban/suburban areas and road networks)



Impervious Surface and Fecal Contamination



Observed Fish Kills

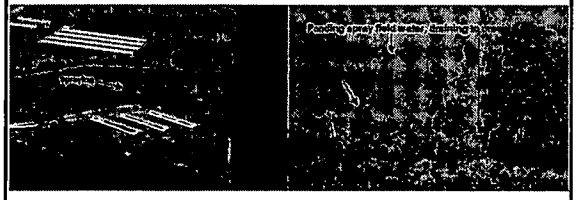


Storm Effects vs. Human Activities

Post *Hurricane Floyd* flooding

Wastewater Storage/Discharge

- Row crop agriculture has declined in North Carolina in recent years
- Animal operations have greatly increased, especially in Coastal Plain
- Waste can enter streams from lagoon breaches, runoff from spray field
- Waste can enter groundwater and increase nitrogen in air

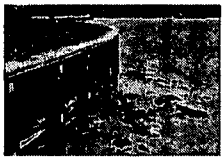


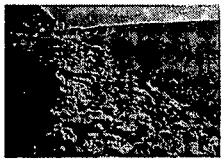
Animal operation - lagoon and spray field. (Photo by DWQ)

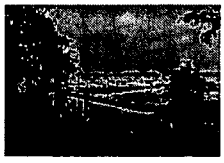
Saturated spray field. Spray effluent puddling on surface and draining to adjacent creek. (Photo by DWQ)

Shoreline Alteration

(Estuarine shoreline stabilization, marinas and docks, and beach nourishment)

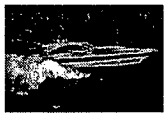


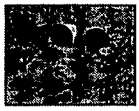


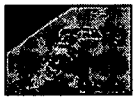


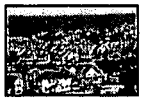
Fishing Practices and Boating Activity

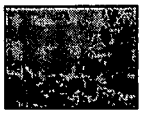
- Clam kicking and oyster dredging dig up soft bottom and oysters, and increase turbidity; some SAV is within clam kicking areas
- Wakes from high speed boat operations erode fringing wetland vegetation, increase turbidity, destabilize shell bottom

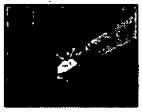


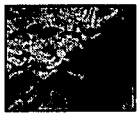


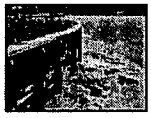












Effects on the Total Habitat System can be Individually Small, but Cumulatively Large

Public Participation

- Public Outreach prior to Public Meetings (10 each year)

2003	2004
- video	- mailings (>600)
- brochure (15,000)	- new tabloid (250,000)
- tabloid (250,000)	- internet (draft CHPP)
- internet	

- Focus of Public Meetings
  - 2003: identify threats & suggest actions
  - 2004: introduce & discuss recommendations
- Comments also received after each years' meetings via telephone, e-mail, U.S. Mail, and in person. Shared with IRC, DENR

Public Participation

- Additional meetings held with interest groups
  - 2003: local govt., agriculture, educators, civic groups
  - 2004: local govt., agriculture, forestry, developers, commercial and sport fishermen
- Estimated # of Internet downloads of draft CHPP
  > 12,000 (July 1 – October 31, 2004)

Public Comments

- Improve enforcement and compliance monitoring
- Coordinate rule-making and enforcement among Commissions and agencies
- Enhance education on habitat and threats
- Reduce stormwater impacts on water quality
- Enough studies – time for action

CHPP Goals & Recommendations

Goal 1 IMPROVE EFFECTIVENESS OF EXISTING RULES AND PROGRAMS PROTECTING COASTAL FISH HABITATS

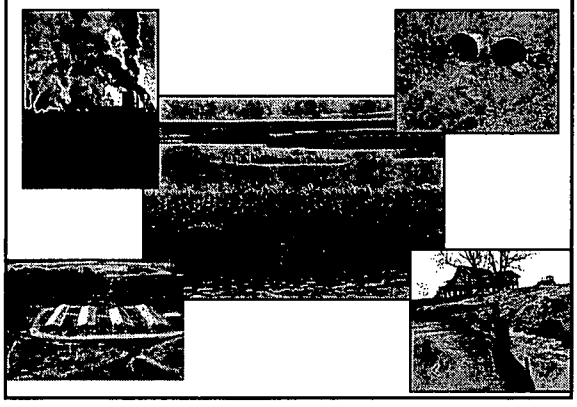
Goal 2 IDENTIFY, DESIGNATE, AND PROTECT STRATEGIC HABITAT AREAS (SHAs)

Goal 3 ENHANCE HABITAT AND PROTECT IT FROM PHYSICAL IMPACTS

Goal 4 ENHANCE AND PROTECT WATER QUALITY

CHPP Schedule

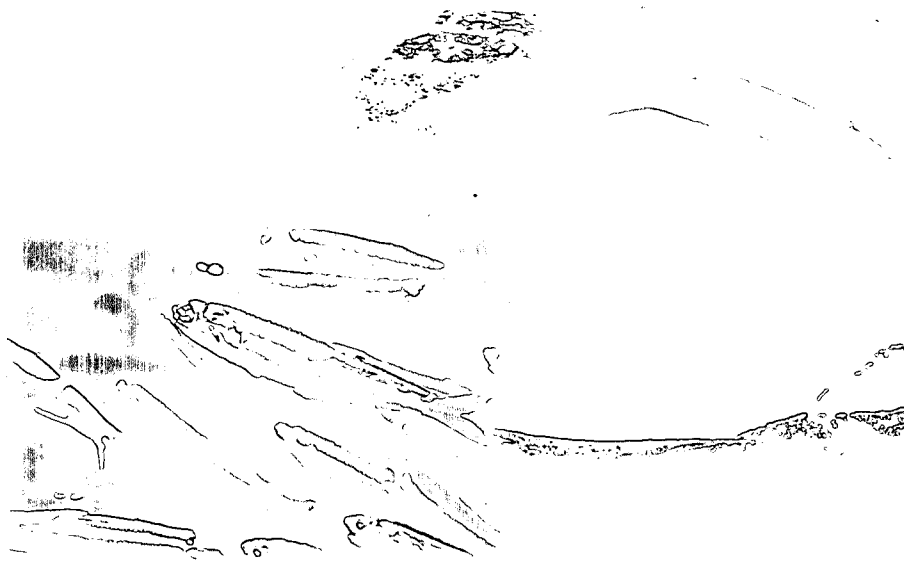
- July & Sept. 2004: Draft CHPP on DMF web site ☑
- July – August 2004: Coast wide public meetings ☑
- September 2004: Draft CHPP to Commissions ☑
- December 2004: Commissions adopt CHPP
- Early 2005: Commissions/DENR prepare implementation plans
- Mid-2005: Begin CHPP Implementation
- Every 5 years: Update CHPP

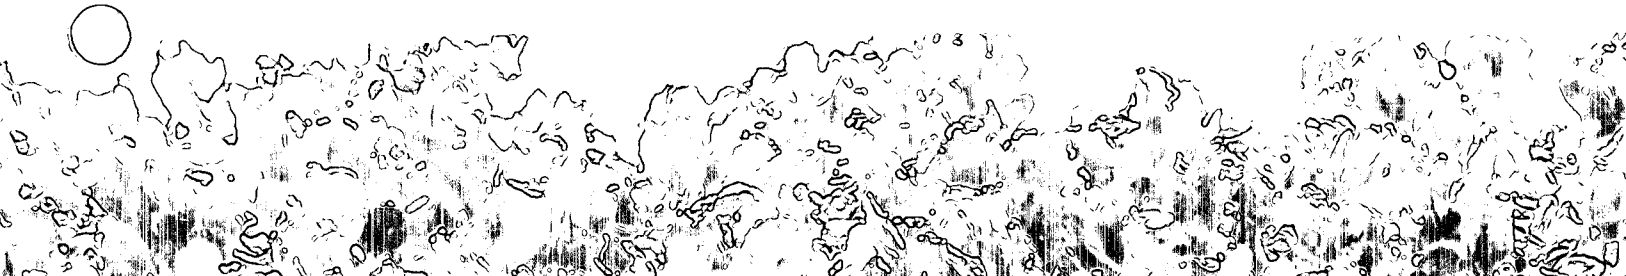


Caring For Our Fisheries

an introduction to the

Coastal Habitat Protection Plan





NCDENR

North Carolina Department of Environment and Natural Resources

Michael F. Easley, Governor

William G. Ross Jr., Secretary

Caring for Our Fisheries

Whether you live, work or play on North Carolina's coast, the condition of our coastal fish habitats affects you. I am pleased to announce that the Department of Environment and Natural Resources has released a bold plan to enhance, restore and protect these important habitats. A requirement of the Fisheries Reform Act of 1997, the Coastal Habitat Protection Plan (CHPP) identifies six vital habitats that sustain the foundation of our state's billion-dollar fishing industries and recommends ways the people of North Carolina can protect or restore them.

In developing the plan, we consulted with scientists, resource managers and commercial and recreational fishermen, and collected input from numerous citizens through two series of public meetings all along the coast. We constructed a plan based on science that balances a need to protect these significant ecological habitats while sustaining fisheries that are vital to our economy. We also tried to create achievable recommendations that will provide substantial benefits for our state.

The pages that follow provide a general introduction to the CHPP, the six vital habitats, and our recommendations submitted to the state's Environmental Management, Coastal Resources and Marine Fisheries commissions. These commissions will be working together to adopt and implement this ground breaking plan.

Please take a few minutes to review this publication. With your help and participation, we can protect and restore the critical fish habitats along our coast, with resulting benefits to the people and creatures who are sustained, entertained and inspired by our coast and its waters.

Thank you for your interest and dedication to improving those critical habitats upon which the fish and we depend so greatly.

William G. Ross, Jr.
Secretary,
N.C. Department of Environment and Natural Resources

One North Carolina Naturally

Caring for Our Fisheries-

the Coastal Habitat Protection Plan (CHPP)

North Carolina's approximately 2.9 million acres of estuarine and marine waters comprise the largest estuarine system of any state along the Atlantic coast. These waters are not only vital for the state's important fish species, but are also critical to many of the fish that migrate along the East Coast from Florida to Maine. North Carolina, with its billion dollar commercial and recreational fishing industries, ranks among the nation's highest in seafood-producing states. Fish and shellfish species important to these industries depend on the quality and quantity of habitats found along our rivers, sounds and ocean waters. From shellfish beds, mud flats and marshes to freshwater streams and swamps, fish habitats once healthy and thought to be inexhaustible are in jeopardy. Pressures from development, loss of habitat, pollution and degraded water quality threaten more than an industry vital to North Carolina's economy. At stake are a way of life and the very character of North Carolina's coastal region.

A system of interconnected fish habitats provides the basic needs of fish and shellfish, including food, shelter and places to reproduce and grow.

Recognizing these threats, the N.C. General Assembly passed the Fisheries Reform Act of 1997. This law requires the state's Environmental Management, Coastal Resources and Marine Fisheries commissions to adopt a plan to protect and restore resources critical to North Carolina's commercial and recreational fisheries. The Department of Environment and Natural Resources (DENR) has been working since 1999 to develop the Coastal Habitat Protection Plan (CHPP) for the long-term enhancement of fisheries associated with coastal habitats.

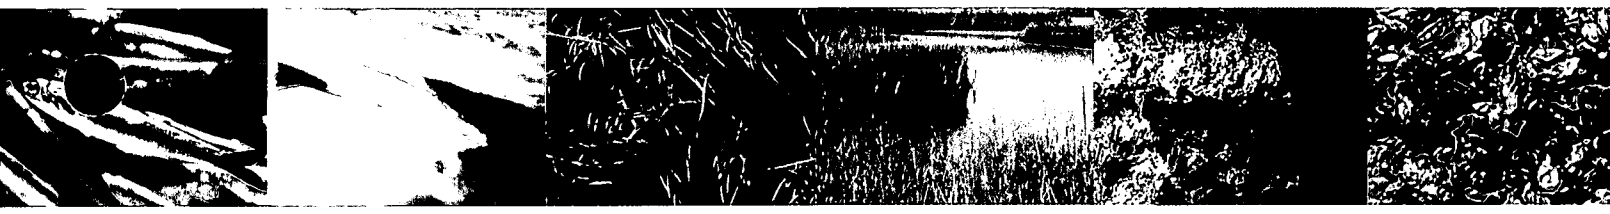
The CHPP is a detailed document, more than 500 pages long, describing the six major fish habitats and providing scientific information on their ecological functions and importance to marine species. It also identifies the threats to each habitat and recommends needed administrative, regulatory and research steps to protect and enhance each habitat.

The CHPP was developed through a cooperative, multi-agency effort with public input and sets the stage for unprecedented fish habitat protection and restoration initiatives. This booklet provides a brief introduction to the Plan's six fish habitats and why it benefits all of us to manage them wisely. Included in the back folder are the recommendations for research needs and for management actions to care for our fisheries.

Visit http://www.ncdmf.net to learn more about the CHPP or to download a copy of the report. Questions and comments can be directed to chpps@ncmail.net or by calling (252) 726-7021 or 800-682-2632.

The CHPP identifies six habitats that need protection or enhancement:

- Water Column
- Shell Bottom
- Submerged Aquatic Vegetation (SAV)
- Wetlands
- Soft Bottom
- Hard Bottom



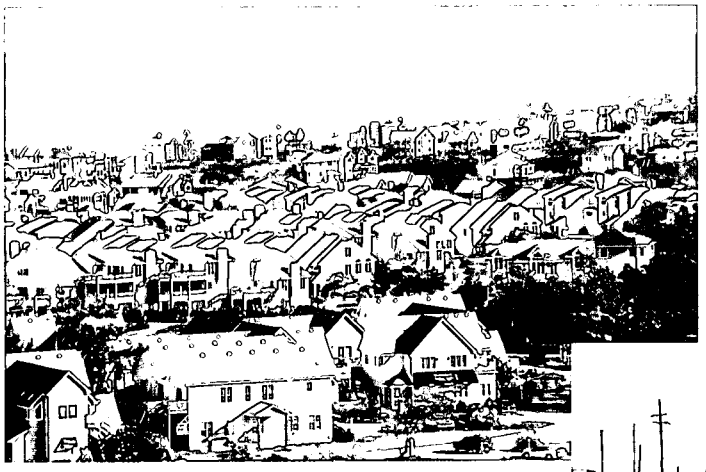
North Carolina is located at the convergence of the warm Gulf Stream flowing north and cool Labrador Current flowing south. These currents bring a wide variety of fish species into our coastal waters. The state's central location, vast estuarine system and extensive shoreline all play important roles in the health of fisheries all along the Atlantic coast. Maintaining healthy coastal habitats supports fish production and also benefits coastal residents and visitors.

Although different habitats are occupied by a variety of species, all fish habitats are integral components of the entire aquatic ecosystem because the water column connects them all. Organisms are not randomly or evenly distributed in aquatic systems. They occupy specific areas or habitats that meet their needs for each particular stage in their life. Certain areas are especially important to fish production, and some are particularly vulnerable to human impacts. To maintain a healthy coastal ecosystem it is not sufficient to protect individual habitat types – it is more effective to address the entire system of interdependent habitats.

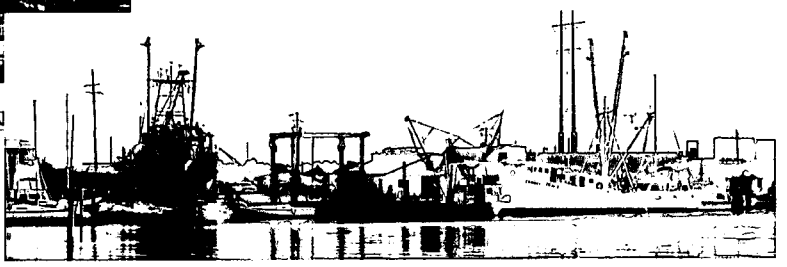
Because all fish habitats are connected through the water column, maintaining and restoring water quality is the basic component of habitat protection and enhancement. Runoff from developed land (buildings, parking lots, roads and lawns), agricultural operations, and intensively managed forests carries excess nutrients, excess sediment and other pollutants into surface waters. Excess nutrients can lead to algal blooms that reduce water clarity and decrease dissolved oxygen, leading to fish kills.

Credit: NOAA – Seawifs Satellite

The Gulf Stream brings southern species (such as shrimp, Spanish and king mackerel, snapper, and grouper) while the Labrador Current brings northern species (such as tautog, summer flounder, Atlantic mackerel).



Our developing coast....



Excess sediment clouds the water, reduces growth and survival of sea grasses and shellfish, and impairs spawning and nursery habitats. Pollutants such as heavy metals and pesticides that are carried with stormwater can accumulate in bottom sediments and contaminate fish and shellfish, making them unsafe for human consumption. Rainfall runoff also carries harmful bacteria and viruses to our rivers, sounds and beaches, requiring tens of thousands of acres of shellfishing waters to be closed for harvest to protect human health.

Estuary – where fresh water mixes with salty ocean water – our Sounds

Habitats provide important functions for fish species.

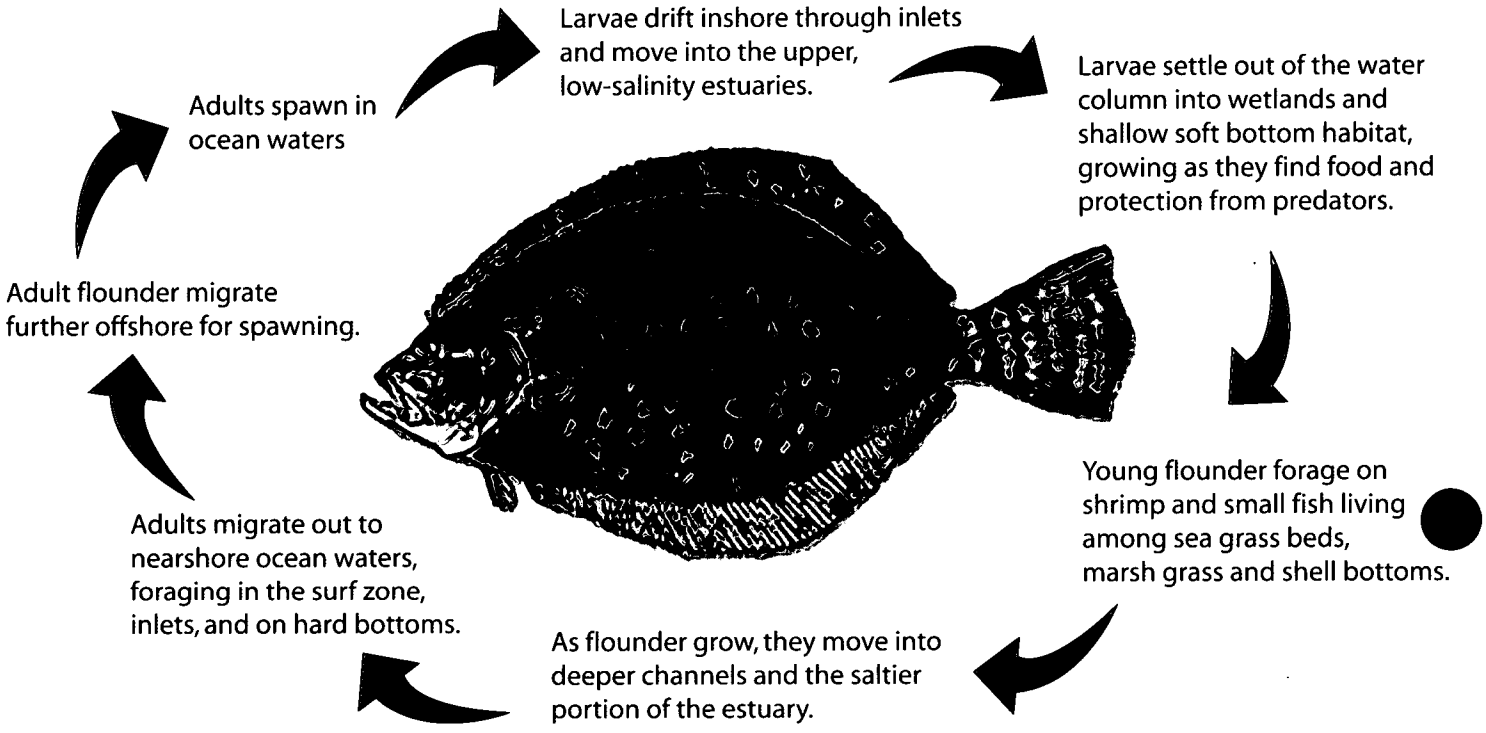
Refuge:	shelter for fish at various life stages and a place for plants and animals to attach
Nursery:	refuge and foraging habitat suitable for development of juvenile life stages of fish, shellfish and crabs
Spawning:	conditions that allow adults to reproduce
Foraging:	presence and accessibility of food sources
Corridor:	connectivity for safe passage between foraging, spawning and refuge areas

Complex habitats serve many functions.

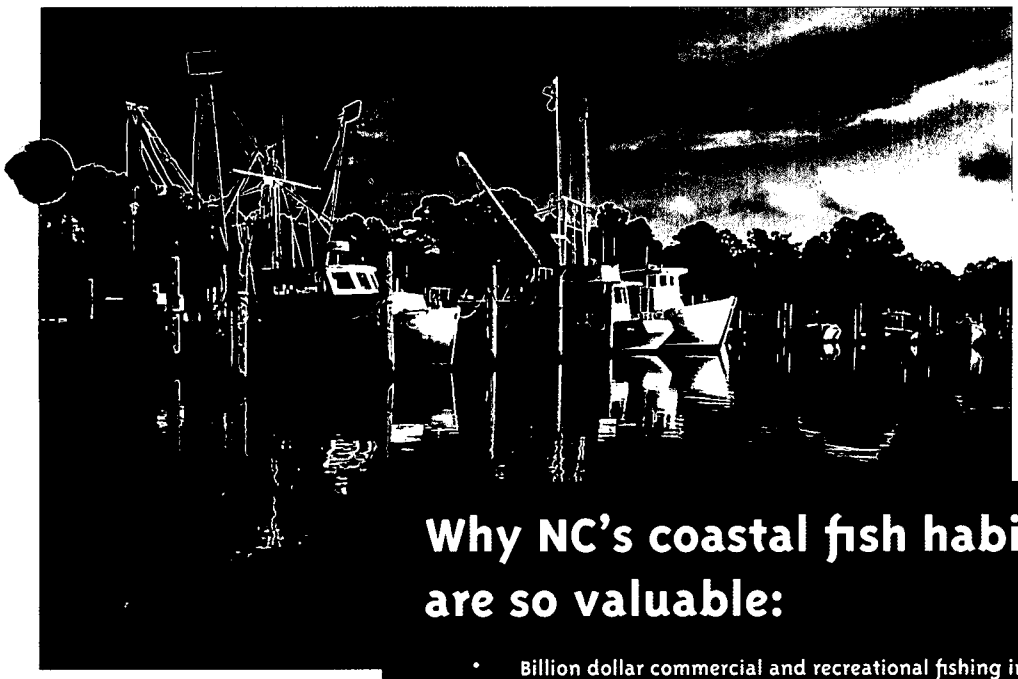
Caring for our Fisheries

While poor water quality puts the ability of habitats to function and support fish populations at risk, physical damage caused by humans is also a serious threat. Conversion of wetlands by draining, filling and water control projects are the major sources of wetland loss in eastern North Carolina. Shell bottom habitat along our coast has been decimated by a century of excessive mechanical harvests and diseases. More recently, dredging for navigation channels and marinas, as well as damage from trawling and other harmful fishing methods, have continued to reduce remaining shell bottom habitat and impede establishment of new shell bottom. Submerged aquatic vegetation is highly vulnerable to physical disturbances from boat propellers and bottom-disturbing fishing gear and to shading by docks and piers. These and other types of physical impacts affect the ability of fish habitats to sustain fisheries and increase their vulnerability to water quality problems.

Southern flounder uses all coastal habitat types during its life



The relationship of habitat conditions to the fishing industry is important and complex. In the past, the decline of a particular fish stock was often attributed to overfishing. We know now that the condition and quantity of fish habitats is important to healthy fish populations. Habitat loss and degradation make fish populations more susceptible to overfishing and can cause a delay in recovery even after management actions have successfully reduced fishing pressures. Thus, the status of fisheries can be an indicator of impacts to fish habitats. Successful implementation of the Coastal Habitat Protection Plan recommendations will help support productive fisheries for future generations.



Why NC's coastal fish habitats are so valuable:

- Billion dollar commercial and recreational fishing industry
- Largest system of estuaries and ocean waters of any Atlantic Coastal State
- Located at the meeting point of warm southern and cool northern currents
- Includes 6 distinct, but interdependent, habitats used by finfish and shellfish
- A strong heritage of commercial and recreational fishing
- Essential to a sustainable economy

North Carolina's coastal fish habitats provide important functions for the plants and animals living in them. This diversity of interconnected habitats provides food, shelter and places to reproduce and grow for a tremendous variety of fish, shellfish and crustaceans. Protecting and restoring these habitats is essential to the survival of North Carolina's fisheries.

Habitat: "a place, or set of places, in which a fish or fish population finds the physical, chemical, and biological features needed for life."

Coastal Habitat Protection Plan

NCDENR

Information for map was collected from various sources. Every effort has been made to ensure the quality and accuracy of this information. Map should be used for general reference only.

Water column is the habitat that connects and supports all aquatic plants and animals. It affects all other coastal fish habitats that it covers.

For fish and other aquatic plants and animals — water means life. All finfish, shrimp, crab and shellfish habitats depend on water to sustain them, so the quality of that water is a key factor that links fish, habitat and people. This is why the water column is the most essential habitat required for the growth, survival and reproduction of fish, shellfish and other aquatic species.

Fish travel through the water column to other coastal habitats that have suitable conditions for their current life stage – from freshwater rivers through brackish sounds into the saltier open ocean. Many aquatic species also move as water temperature changes, prompting them to migrate to their spawning grounds. Eggs and larvae can be carried through the water column to habitats favorable for their survival and growth. Particularly important areas of the water column include rivers, inlets, shallow estuarine spawning and nursery areas, and the nearshore surf zone.

Threats to Water Quality

Whether certain species will thrive and reproduce is strongly affected by conditions like water clarity, and oxygen and nutrient levels. Fish kills and harmful algal blooms during the 1980s and 1990s made it easy to see declines in coastal water quality. Although large fish kills and algal blooms have diminished somewhat in recent years, many coastal waters remain impaired.

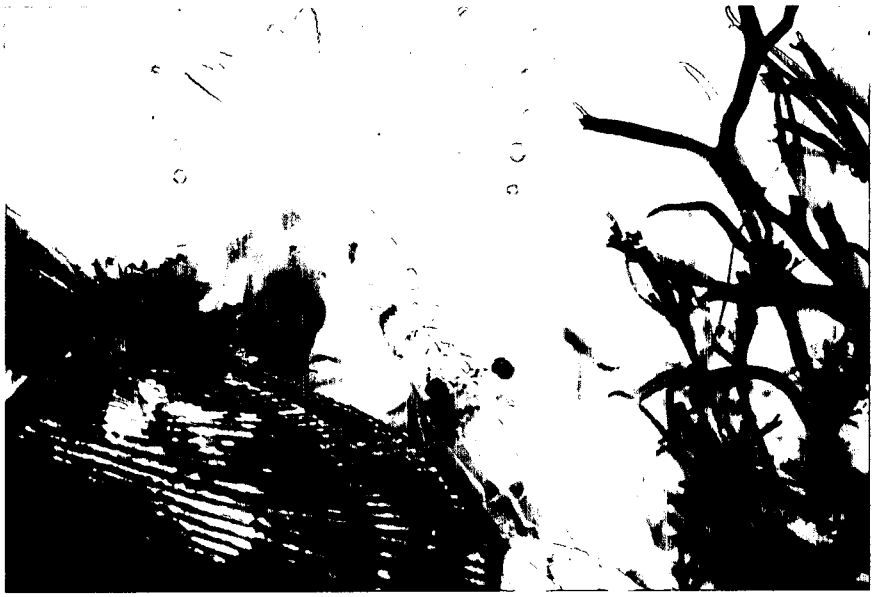
The condition of the water column also influences the health of other coastal habitats. For example, water depleted of oxygen by algae and bacteria can kill many animals inhabiting ***shell bottom*** and ***soft bottom*** habitats. Such oxygen depletion can occur due to natural events, but the chances of fish kills are much greater if there are too many nutrients in the water carried by runoff from developed or agricultural lands. Excessive nutrients can also lead to the death of ***submerged aquatic vegetation (SAV).*** In addition to algae, excessive sediment can cloud the water, which can shade ***SAV,*** and can smother aquatic life in ***shell, hard*** and ***soft bottom*** habitats. Additionally, chemicals and wastes in runoff after rainfall can kill or infect fish, shellfish, birds and people.

The ability of fish species of various life stages to move freely through the aquatic system is a critical component of a healthy water column habitat. Unobstructed waterways and natural flow patterns are particularly important to species that swim upstream to spawn in freshwater. More than 2,000 dams in North Carolina affect natural stream flow to coastal waters. Many streams have been straightened and deepened. Countless road crossings obstruct the natural flow of streams. The removal of obstructions to restore flow in streams and rivers has been highly successful in restoring populations of striped bass, American shad and river herring.

Human activities often change the chemistry of the water, reducing water quality. These changes can originate from point sources, such as industrial or wastewater discharges, or from development that allow pollutants and sediment to be carried in rainfall runoff. It is obvious how excess sediment clouds the water and fills a waterway, but beneath the water's surface, these particles also clog fish gills and bury plants, shellfish and other aquatic species.

Clean water is essential to aquatic life.

Numerous studies indicate that when impervious surfaces, such as roads, rooftops and parking lots, exceed 10 percent of a watershed's land area, water quality becomes impaired and habitats are damaged. It is estimated that more than half of North Carolina's coastal draining watersheds will exceed the threshold by 2012. North Carolina's coastal waters may be approaching a turning point in overall quality. **Once this point is reached, water quality and habitat improvements will be more difficult and costly to achieve.**



FACT:
1,315 miles of freshwater streams and nearly 70,000 acres of estuarine waters are classified as impaired in the coastal river basins.

Hope for the Future

The water column surrounds and supports all aquatic organisms and connects all coastal fish habitats. Consequently, clean and healthy waters are critical to the overall viability of coastal fish habitats and aquatic organisms. Therefore, efforts are needed to minimize threats and enhance water quality wherever possible. Sediment, excess nutrients, bacteria and toxins in the water must be reduced by addressing multiple sources. This includes enhancement of urban and agricultural best management practices (BMPs), more stringent controls on construction projects and improved natural buffers along our waterways.

HABITAT PROFILE

WATER COLUMN FUNCTIONS
- Connects all habitat types
- Allows fish to move among habitats
- Surrounds and supports aquatic animals and habitats

HOW FISH USE THE WATER COLUMN
- Transports eggs, larvae, and oxygen
- Nursery area for all fish species
- Foraging area for all fish species
- Spawning area for all fish species

HUMAN IMPACTS
- Excessive runoff after rainfall
- Pollution from toxic chemicals, nutrients and sediment
- Alteration of natural water flow by dams, ditches, roads and culverts
- Conversion of natural areas to agriculture and developed uses
- Loss of shoreline vegetation (buffers)

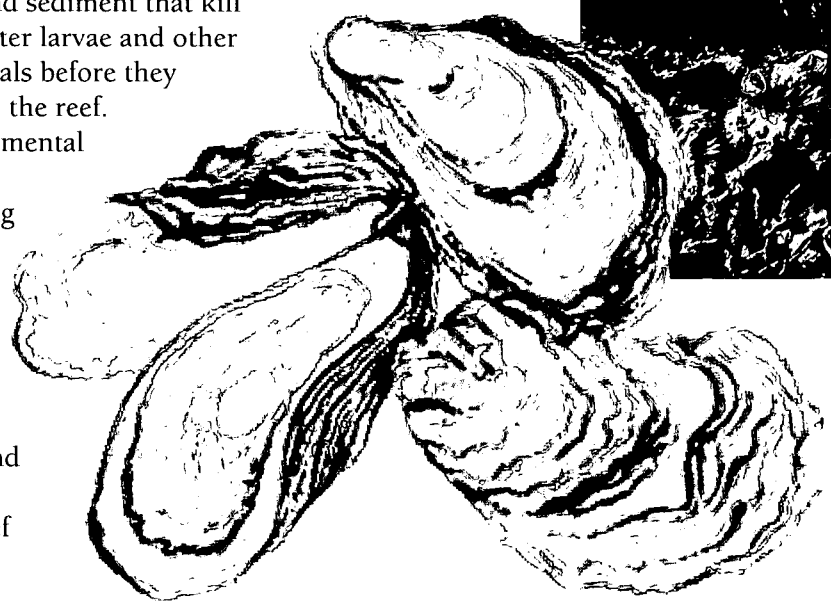
All coastal habitats are connected by water.

Shell bottom areas include reefs made of living oysters or shells, located in the subtidal or intertidal zone of sounds and estuaries.

Shell bottom is unique because it is the only coastal fish habitat that is also a fishery species (oysters). The ecological value of shell bottom has only recently been recognized to be as significant as the fishery itself, since it provides numerous habitat and water quality functions that are vital for other fishery and non-fishery species. Oysters provide habitat for themselves, as well as shelter and forage areas for numerous forms of marine life. These shellfish provide important water quality functions, such as filtering the water, so other animals and plants can survive. By pumping water through their bodies and filtering out food – mostly algae, bacteria and decaying plant material – oysters and other shellfish actually help clean the water. This water filtering ability makes shell bottom important to the overall health of our coastal fish populations.

Shell bottom performs vital functions for many fish species and adjacent habitats. Shellfish can clear dissolved and suspended material from murky water, allowing sunlight to reach nearby submerged aquatic vegetation (SAV). Mollusks attach to the hard, three-dimensional structure of the reef, while small fish, shrimp and crabs hide from predators among the crevices. Larger creatures use the edges of the reef as a good place to hunt for their next meal.

The formerly vast range of shell bottom habitat has shrunk to a fraction of what existed before 1889, when dredging the bottom to harvest oysters began. Since that time, North Carolina's commercial oyster harvest has decreased by 90 percent, indicating a loss of shell bottom resources. Although damage from harvesting has been greatly reduced, the shell bottom habitat has not recovered – largely due to adverse impacts of dredging and trawling, diseases and stormwater runoff containing chemicals and sediment that kill sensitive oyster larvae and other marine animals before they can attach to the reef. This environmental stress makes the remaining adult oysters vulnerable to diseases that kill them before they can reproduce and create more extensive reef systems.

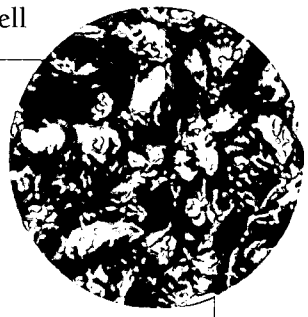


Shell bottom is the only coastal habitat that is also a fishery resource.

Threats to Shell Bottom

Shell bottom used to be found further up the coastal rivers, but increased drainage of stormwater from development, agriculture and forestry into coastal waterways has greatly lowered the salinity, while raising nutrient levels in the shallow Neuse and Pamlico estuaries. Harvesting shellfish without returning the shells continues to reduce this habitat. Damage from bottom-disturbing fishing gear, boats and dredging continue to destroy productive shell bottom. As scientists and lawmakers consider the actions required to restore our shell bottom habitat and oyster population, a way of life central to our coastal heritage hangs in the balance.

Shell bottom is considered to be one of the most threatened habitats because of its greatly reduced extent and because of its connection to other habitat types.



HABITAT PROFILE

SHELL BOTTOM FUNCTIONS

- Provides structure, shelter and food source
- Filters pollutants and other particles from water
- Protects shoreline by slowing wave energy

HOW FISH USE SHELL BOTTOM

- Place for oysters and other shellfish to attach
- Nursery area for blue crab, sheepshead and stone crab
- Foraging area for drum, black sea bass and southern flounder
- Spawning area for hard clams, toadfish and goby
- Refuge for goby, grass shrimp and anchovy

HUMAN IMPACTS

- Destruction by fishing gear, boats and dredging
- Excessive oyster harvest
- Runoff carrying toxic chemicals and sediment
- Excess nutrients causing decreased oxygen
- Excess freshwater inputs from drainage

Hope for the Future

The Division of Marine Fisheries shell bottom restoration efforts began in 1958, and some protected areas have been established. Recent efforts have shifted from restoring oysters just for harvest to enhancing shell bottom for habitat, but losses still greatly exceed gains from oyster habitat restoration. Currently North Carolina is working to rebuild shell bottoms using discarded shells and planting native oyster larvae.

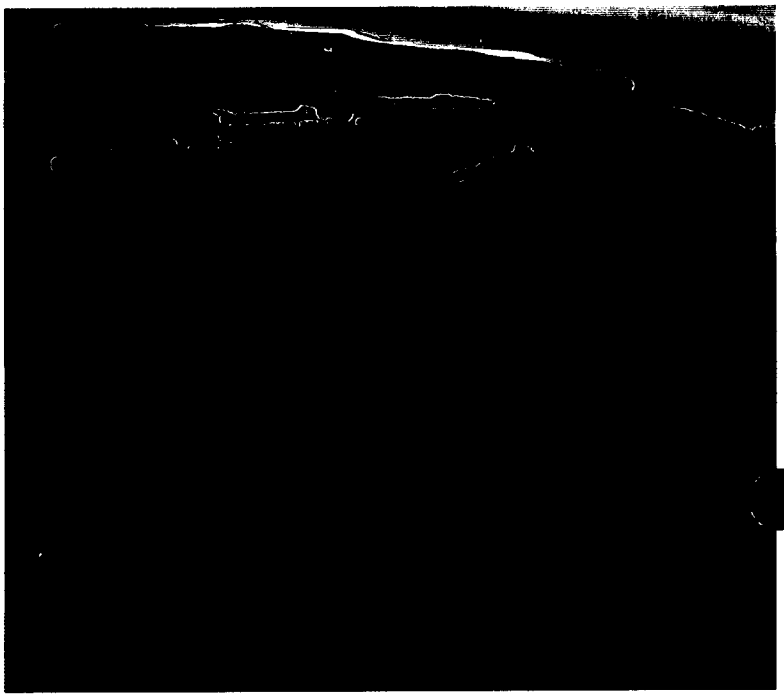
Restoring oyster beds in tidal creeks.

FACT:
Oyster beds were once so abundant that they were considered a navigation hazard.

Shell Bottom - *Building reefs & cleaning water*

Submerged Aquatic Vegetation (SAV) *- this fish habitat is dominated by one or more species of underwater plants, occurring in isolated patches or extensive meadows in shallow water in our sounds and rivers. This habitat includes temporarily unvegetated areas between vegetated patches.*

Like plants in gardens, sea grasses and other underwater plants need light to grow, and can only thrive in clear, relatively shallow waters. The underwater network of leaves and roots traps sediments and adds oxygen to the water. These grass beds form the base of a complex food web for coastal fish and other organisms, including water fowl. When these plants die, the decomposed material becomes food for shrimp, crabs, bacteria and fungi, which are in turn eaten by larger animals.



Many species occupy submerged aquatic vegetation (SAV) habitat at some point in their life cycle, hiding among the leaves or hunting for prey along the edge of the beds. This habitat is especially valuable for the young of many important commercial and recreational fish species, serving as a nursery and as refuge from larger fish. Where large sea grass meadows grow along estuarine shorelines, they absorb wave energy and reduce erosion.

Two types of SAV communities occur along the coast of North Carolina - one in higher salinity estuarine waters in the eastern sounds, and the other in lower salinity systems in the coastal rivers and Albemarle Sound. Both are extremely important to coastal fish species. These underwater gardens can actually move over time as the sands beneath them shift. The high salinity grass beds on the landward side of the Outer Banks appear relatively stable. However, the original extent of sea grass beds has been greatly reduced in low salinity areas on the mainland side of the Pamlico Sound and along much of the shoreline of the western Albemarle Sound. In recent years there has been some recovery of SAV beds in these areas. Once destroyed, SAV habitat is difficult and very expensive to restore, costing up to $1 million per acre.

Threats to SAV habitat

Large amounts of algae and sediment make the water so cloudy that light cannot reach the plants, reducing their growth, survival and productivity. Many everyday activities far from the coast such as land clearing, farming and lawn care practices contribute to polluted storm water runoff and impact SAV habitat. Other activities contribute to the pollution problem, such as wastewater discharges and sediment stirred up by boating, bottom-disturbing fishing gear and channel dredging. Dredges and boat propellers can have a direct effect on SAV habitat by uprooting and destroying the plants.

HABITAT PROFILE

SAV FUNCTIONS

- Provides refuge for fish and other aquatic animals
- Serves as food for fish and waterfowl
- Produces dissolved oxygen
- Reduces wave energy and limits erosion
- Uses nutrients and traps sediments

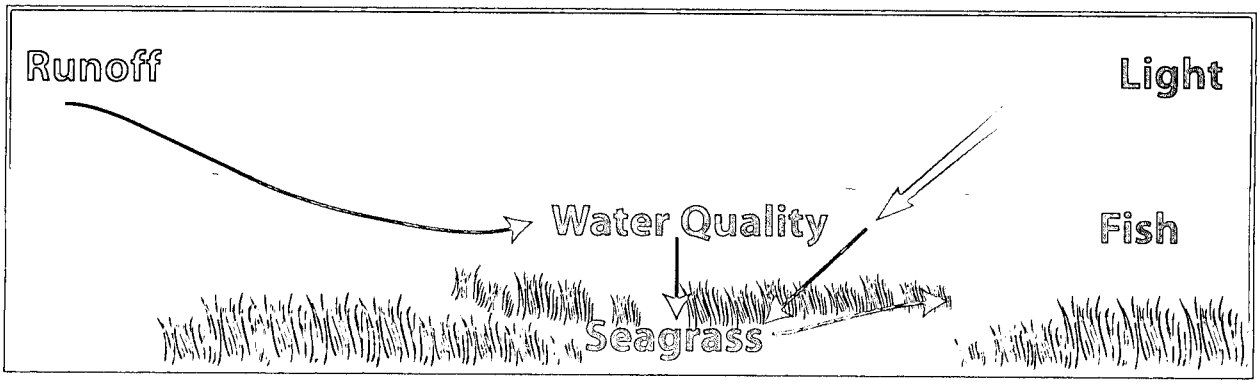
HOW FISH USE GRASS BEDS

- Nursery area for blue crab, pink shrimp and red drum
- Foraging area for spotted sea trout, gag and flounder
- Spawning area for spotted sea trout, grass shrimp and bay scallop
- Refuge for bay scallop and hard clam

HUMAN IMPACTS

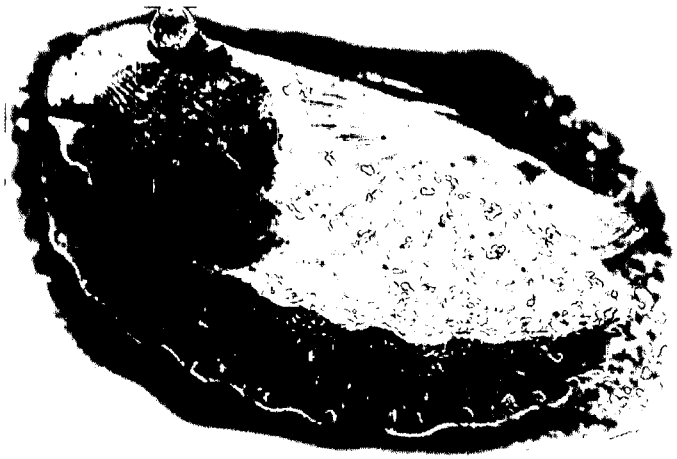
- Uprooting by boat props and fishing gear
- Pollution from excess nutrients
- Buried under excess sediment
- Shading by piers and docks
- Destruction from dredging and filling

FACT:
More than 40 different fish species use SAV habitat at some stage of their life.



Hope for the future

As human population and coastal development pressures increase, loss of SAV habitat will continue unless steps are taken to protect it and maintain suitable water quality. North Carolina needs to ensure that SAV habitat is protected from physical disturbances such as damage caused by boats and bottom disturbing fishing gear as well as make improvements in water quality and clarity.



SAV provides shelter, food and oxygen.

*A **wetland** is a lowland area, such as a marsh or swamp, that is saturated or flooded with fresh or salt water and contains plants adapted to wet conditions. Wetlands are essential to many fish and animals.*

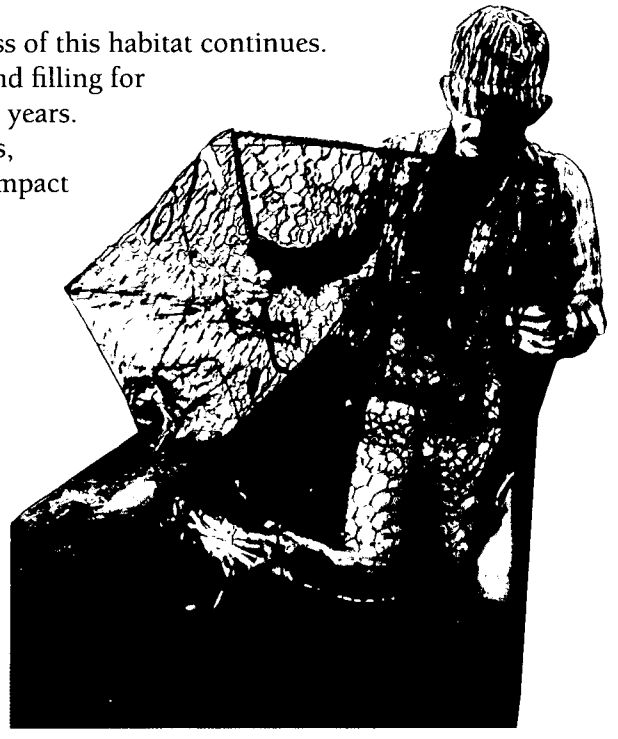
Early North Carolina settlers thought the only good swamp was a drained one, and quickly started draining wetlands for agriculture and development. We now have some understanding of the vital roles that wetlands play in providing habitat, along with slowing down rainfall runoff, reducing flooding, and recharging underground aquifers for our drinking water supply.

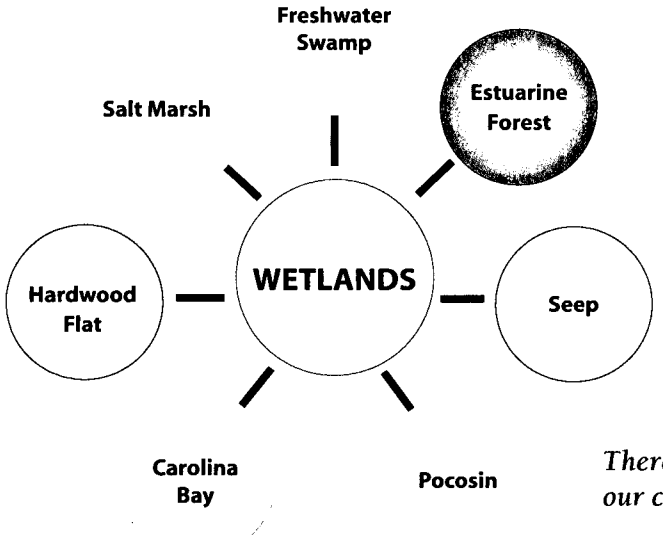
Wetlands are critical to a large number of fish species. At least 95 percent of the United States' commercially harvested finfish, shellfish and crabs depend on wetlands at some time during their life. The combination of shallow water and vegetation makes excellent nursery habitat for young fish, providing both food and refuge. Wetlands provide a protected corridor for fish to move among other habitats. The majority of North Carolina's designated Primary Nursery Areas include wetlands along with the adjacent shallow water and soft bottom.

North Carolina has many different types of wetlands. They can be open and grassy or forested. Each type of wetland is important in keeping our rivers, sounds and coastal waters clean and providing food and sanctuary for many fish and other animals.

Threats to Wetlands

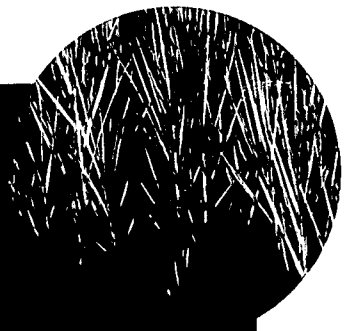
Half of North Carolina's original wetlands have been lost, and loss of this habitat continues. Ditching and draining for roads, construction of dams, mining and filling for development account for the majority of wetland losses in recent years. Additionally, small losses – from small actions (building of docks, bulkheads, filling and dredging) – add up to a large cumulative impact that affects the whole ecosystem.





There are many types of wetlands in our coastal region.

Coastal wetlands border vital nursery areas and serve as the primary buffer between land and water-based impacts.



HABITAT PROFILE

WETLAND FUNCTIONS

- Provide refuge and food for fish and other animals
- Filter pollutants
- Trap sediments
- Protect the shoreline by slowing wave energy
- Hold and slowly release flood waters

HOW FISH USE WETLANDS

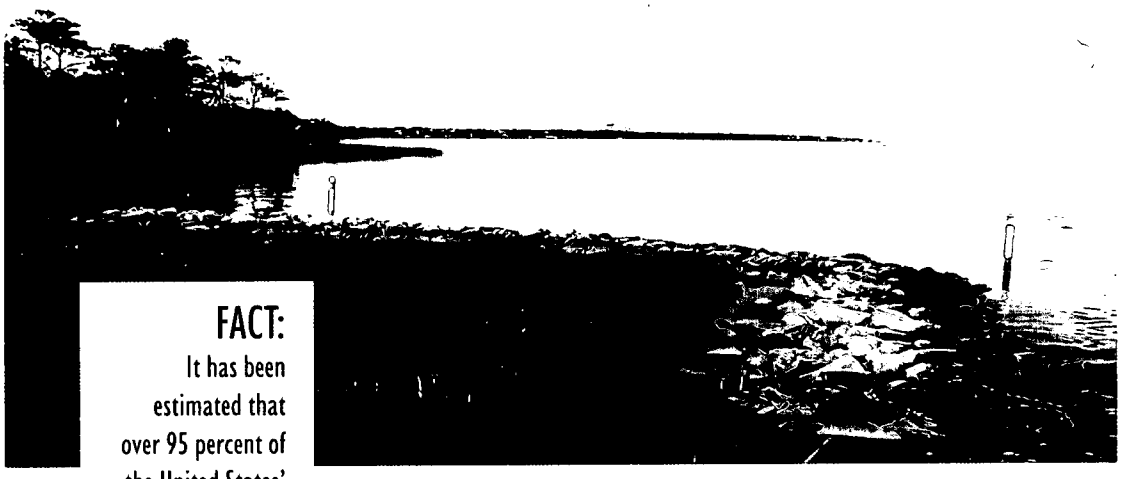
- Nursery area for blue crab, shrimp and southern flounder
- Foraging area for sea trout, red drum and flounder
- Spawning area for river herring, killifish and grass shrimp
- Refuge area for blue crab and grass shrimp

HUMAN IMPACTS

- Draining and ditching
- Filling for development
- Erosion from boat wakes and shoreline development
- Bulkheads and rip-rap

Hope for the Future

Current efforts such as buffer establishment, wetland restoration, land acquisition and preservation, and use of agricultural-forestry best management practices have lessened the impact on our wetlands. Rules protecting wetlands and reducing pollution have saved many acres from destruction. Additional actions are necessary to protect and enhance wetland habitat. The many fishery and water quality functions provided by wetlands make their preservation and restoration along North Carolina's coast a high priority.



FACT:
It has been estimated that over 95 percent of the United States' commercially harvested finfish and shellfish are wetland dependent.

Soft bottom includes muddy and sandy areas beneath coastal rivers, sounds and the ocean, where sediment moves with the waves so that plants cannot establish roots. It includes features such as mud flats, inlets, shoals, channel bottoms and ocean beaches.

Although soft bottom is defined as "unvegetated" and lacks visible structure, the sediments support an abundance of microscopic plants, worms, clams and bacteria. Like SAV, soft bottom is home to many tiny plants that use sunlight to grow. Other very small creatures graze on these algae, bacteria and fungi that grow on or near the soft bottom surface. Fish, shrimp and crabs forage on the bottom, while clams burrow into the mud or sand. Predators like sharks often hunt in soft bottom areas where water is deeper and flounder bury themselves in soft bottom to ambush prey.

Soft bottom habitat takes many forms throughout the coastal area, from freshwater creek bottoms to mud flats in the estuaries, and even includes inlets, sand bars, and shoals, along with the surf zone at the beach. Lacking the kind of structure provided in other habitats by shells, rocks or plants, the sediment itself must absorb the force of the waves. Normally, the currents and tides simply shift the sediments around within the area. When storm-driven wind and waves batter sand, the effect may be the relocation of channels, inlets and the barrier islands themselves. The soft bottom habitat is relatively resistant to this natural changing environment.

During each tidal cycle, as the bottom is exposed and then submerged, there are major shifts in temperature, salinity and contact with the air. Chemicals, excess nutrients and other pollutants that have been carried from local shorelines or far upstream settle into the sediment. This habitat also features the important ability to move many chemicals and essential elements in and out of the water column, storing them under certain conditions and releasing them at other times.

Dredging activities can impact soft bottom habitats.

Threats to Soft Bottom

Although years of land-based activities, pollution and toxic chemicals have adversely affected this habitat, inadequate information is available to clearly determine the current condition of soft bottom. In addition, many human activities aimed at enhancing the "coastal experience" inadvertently degrade this habitat. These important bottom areas are easily damaged by activities such as dredging and beach nourishment, building docks and marinas, and by certain types of fishing gear. Along the oceanfront, jetties form barriers to the movement of sand, altering the natural sediment cycle. Water quality problems that deplete oxygen and cause toxic chemical contamination can impact this habitat on which so many aquatic animals depend.

This habitat strongly influences the water column through its constant cycling of nutrients and sediments.

HABITAT PROFILE

SOFT BOTTOM FUNCTIONS

- Stores and recycles nutrients, microbes and chemicals
- Is a source of sand for other habitats
- Provides an area for marine animals to burrow

HOW FISH USE SOFT BOTTOM

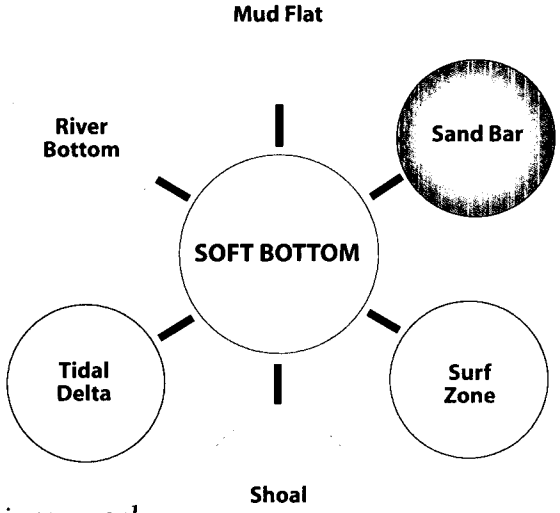
- Nursery area for blue crab, flounder and croaker
- Foraging area for sea trout, red drum and flounder
- Spawning area for shrimp, sturgeon and kingfish
- Refuge area for hard clam, shrimp and flounder

HUMAN IMPACTS

- Disturbance from dredging, filling and fishing gear
- Construction of docks, jetties and bulkheads
- Excavation for mining and beach nourishment

Hope for the future

A few basic modifications in human behavior can greatly improve the situation for the soft bottom habitat. We can minimize dredging in productive shallow bottom areas, properly manage beach nourishment projects and modify shoreline stabilization methods. Meanwhile, efforts to reduce polluted runoff from paved areas upstream can help keep the excess nutrients and toxins from reaching the coastal waters where they become trapped in the sediment. These are the primary management needs to protect and enhance the soft bottom habitat.



Soft bottom habitat is commonly called by many names.

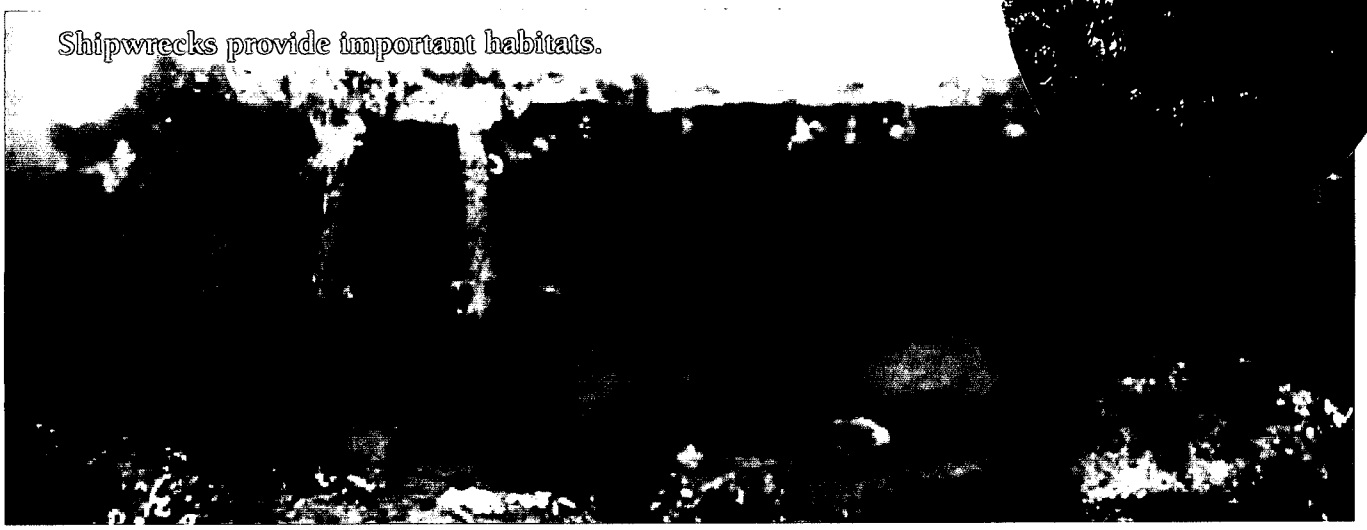
FACT:
Soft bottom covers about 2.3 million acres of estuarine and ocean bottom within State waters.

***Hard bottom** includes exposed areas of rock or other structures, primarily in the ocean, that provide a surface to which coral, algae and sponges can attach.*

Deep-sea anglers and divers know that if they want to find concentrations of fish, they need to locate a rocky reef or a sunken ship. Algae, sponges and other encrusting marine life colonize on naturally occurring rocks, ships and artificial reefs resulting in a complex habitat that provides protective cover. Fish are attracted to these rocky outcrops and structures for food, spawning and shelter. Larger fish will also congregate at these reefs to feed on smaller fish hiding in the nooks and crannies.

Hard bottom can be found nearshore and in deeper ocean waters. Combined with suitable water temperatures, this habitat supports a wide range of reef fish and a snapper-grouper fishery in North Carolina. Many economically important species, such as black sea bass, start their lives on nearshore hard bottom and use this area as a second nursery, moving between estuarine areas and offshore reefs. North Carolina's abundant shipwrecks and artificial reefs add to the total amount of hard structure available to marine organisms and may reduce fishing pressure on natural reefs.

Photo: Harold Quidley



Shipwrecks provide important habitats.

Photo: NOAA

FACT:

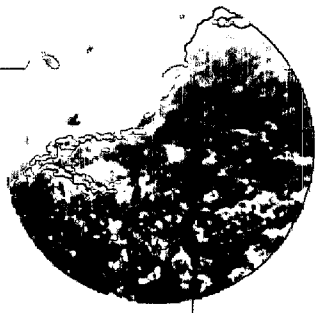
39 artificial reefs are located in ocean waters along North Carolina's coast and seven are located in estuarine waters. In addition, there are numerous shipwrecks along the coast providing habitat for reef-dwelling species.

Threats to Hard Bottom

Threats to nearshore hard bottom habitat in North Carolina include beach nourishment, channel dredging, bottom-disturbing fishing gear and water quality degradation. Channel dredging can directly remove hard bottom habitat or stir up enough sediment to smother the reef. Sand from nourished beaches can also cover hard bottom structures. Fishing gear that disturbs the bottom, such as boat anchors and bottom trawls, can uproot coral and tear loose chunks of rock. Poor water quality caused by excess nutrients, sediment, or toxins can impact growth or survival of the invertebrates living on hard bottom structure

Hope for the future

While artificial reefs have been shown to provide benefits for fish that use reef habitat, they do not fully replace all of the habitat functions provided by natural hard bottom. Management measures are being taken to protect this natural hard bottom from direct impacts including harvest and gear limitations. Additional measures to address water quality effects are needed. Since most of the polluted water that reaches near shore hard bottom areas originates from upstream sources, improving the quality of water flowing from estuaries into marine waters may have the largest overall positive effect.



HABITAT PROFILE

HARD BOTTOM FUNCTIONS

- Provides a place for sponges, seaweed and coral to attach
- Offers refuge for reef fish
- Supplies new sand through erosion

HOW FISH USE HARD BOTTOM

- Nursery habitat for goby, snapper and black sea bass
- Foraging area for king mackerel, gag and snapper
- Spawning area for black sea bass, grouper and damselfish
- Refuge area for goby, gag and black sea bass

HUMAN IMPACTS

- Dredging for beach nourishment
- Damage from fishing gear, boat anchors and ocean dumping
- Harvesting of coral

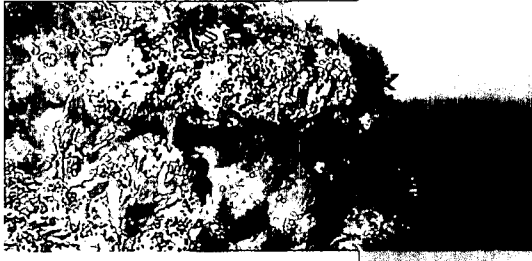
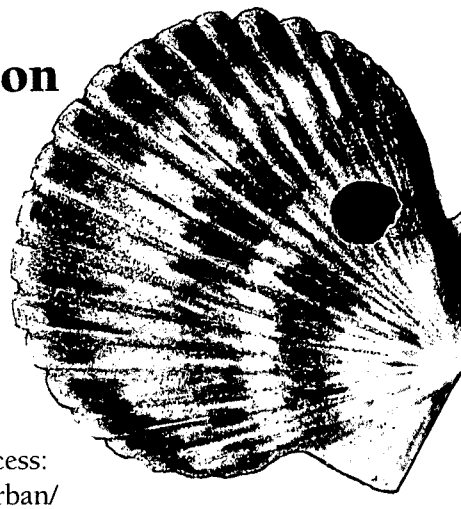
The Hard Bottom habitat of the North Carolina coast is considered crucial spawning habitat for many commercially important species of grouper and snapper.



Recommendations for enhancement, restoration and protection of North Carolina Coastal Fish Habitats



After reviewing the results of hundreds of scientific studies along with input from experts and citizens alike, it became apparent that North Carolina's coastal fish habitats are seriously threatened and in need of protection, restoration and additional research.

Major threats revealed by the Coastal Habitat Protection Plan (CHPP) development process:

Human activities provide substantial impacts, particularly from development (urban/suburban), agriculture, transportation, channel dredging, marinas, bulkheads, docks and some forestry practices.

The most threatened habitats are shell bottom and water column: shell bottom because of its greatly reduced size, and the water column because there are so many pollution sources. Both habitats have connections to all the other habitat types.

Stormwater runoff presents the greatest single threat to North Carolina's coastal fish habitats, carrying sediment, wastes, excess nutrients, toxic chemicals and other pollutants into coastal waters, reducing water quality and clarity, promoting algal blooms, decreasing dissolved oxygen, and reducing the benefits a healthy coastal system provides to coastal residents and visitors.

The CHPP development process identified hundreds of management needs associated with each of the six habitats detailed in the CHPP. The Plan itself describes these management needs in the text of the habitat chapters. The final management recommendations are a result of scientific studies and deliberations of the Environmental Management, Marine Fisheries and the Coastal Resources commissions, along with input from citizens who attended 20 public meetings held during the development of the CHPP.

The recommendations are organized according to four general habitat protection goals:

GOAL 1. IMPROVE EFFECTIVENESS OF EXISTING RULES AND PROGRAMS PROTECTING COASTAL FISH HABITATS.

GOAL 2. IDENTIFY, DESIGNATE, AND PROTECT STRATEGIC HABITAT AREAS.

GOAL 3. ENHANCE HABITAT AND PROTECT IT FROM PHYSICAL IMPACTS.

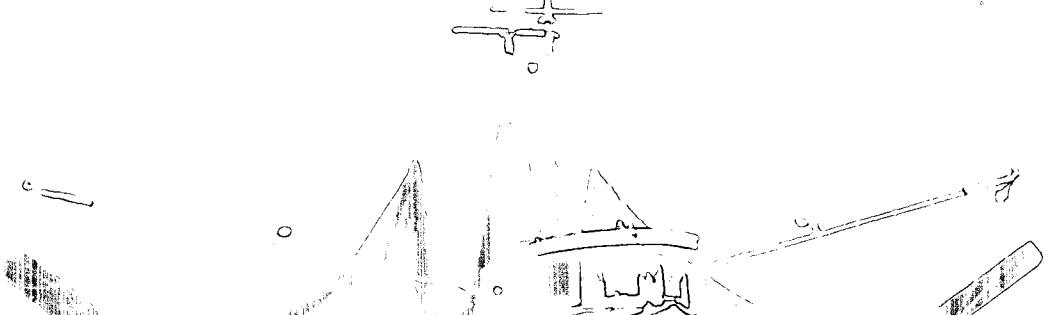
GOAL 4. ENHANCE AND PROTECT WATER QUALITY.

A summary of the recommendations is included in the pocket on the next page. Please refer to Chapter Nine of the CHPP for more details on these recommendations and to the habitat chapters in the Plan for information on how these management actions relate to each specific coastal fish habitat.

No state funds were used to produce this document.
This document was printed with funds provided by the National Oceanic and Atmospheric Administration through a grant to the NC Department of Environment & Natural Resources (Award #NA03NOS4190094).

"When one tugs at a single thing in nature, he finds it attached to the rest of the world."

- John Muir



IMPROVE EFFECTIVENESS OF EXISTING RULES AND PROGRAMS PROTECTING COASTAL FISH HABITATS

- Enhance enforcement of, and compliance with, Coastal Resources Commission (CRC), Environmental Management Commission (EMC), and Marine Fisheries Commission (MFC) rules and permit conditions.
- Coordinate and enhance water quality, physical habitat, and fisheries resource monitoring (including data management) from headwaters to the nearshore ocean.
- Enhance and expand educational outreach on the value of fish habitat, threats from human activities, effects of non-native species, and reasons for management measures.
- Coordinate rulemaking and enforcement among regulatory commissions and agencies.

North Carolina has a number of programs already in place to protect coastal fisheries and the natural resources that support them. The Marine Fisheries Commission has adopted rules addressing the impacts of certain types of fishing gear and fishing practices that may damage fish habitats. The Coastal Resources Commission regulates development impacts on certain types of critical habitat, such as saltwater marshes and primary nursery areas. The Environmental Management Commission has issued water quality standards that address pollution of coastal waters from both direct discharges and runoff. The Coastal Habitat Protection Plan has identified a number of gaps in the protection provided for critical fish habitats under these programs, but also notes that these habitats would benefit from stronger enforcement of existing regulations and better coordination among agencies.

- Develop and implement a comprehensive coastal marina and dock management plan and policy to prevent closures of shellfish harvest waters and minimize cumulative impacts on fish habitat.
- Reduce non-point source pollution from large-scale animal operations by the following actions:
  - support early implementation of environmentally superior alternatives to the current lagoon and spray field systems as identified under the Smithfield Agreement and continue the moratorium on new/expanded swine operations until alternative waste treatment technology is implemented,
  - seek additional funding to phase-out large-scale animal operations in sensitive areas and relocate operations from sensitive areas, and
  - use improved siting criteria to protect fish habitat.

Good water quality is essential to coastal fisheries because water is the common element in all the fish habitats. The water conditions necessary to support coastal fisheries include the right combination of temperature and salinity as well as the absence of harmful pollutants. Achieving and maintaining good water quality for purposes of fisheries productivity requires management of both direct discharges of pollutants and stormwater runoff. The CHPP provides additional support for policies directed toward better management of point and nonpoint sources of water pollution. In doing so, the CHPP recognizes a need to go beyond relying on regulatory programs alone. Addressing water quality impacts will also require targeted use of land acquisition programs, incentives for conservation, development of effective best management practices and assistance for local governments to upgrade wastewater infrastructure. Maintaining the water quality necessary to support vital coastal fisheries will not only benefit the commercial fishing industry – it will benefit a large sector of the entire coastal economy built around travel and tourism and recreational fishing.

Summary of DENR Recommendations (continues on back)*

GOAL 1: Improve Effectiveness of Existing Rules and Programs Protecting Coastal Fish Habitats
Enhance enforcement of, and compliance with, Coastal Resources, Environmental Management and Marine Fisheries Commissions rules and permit conditions.
Coordinate and enhance water quality, physical habitat, and fisheries resource monitoring (including data management) from headwaters to the nearshore ocean.
Enhance and expand educational outreach on the value of fish habitat, threats from human activities, effects of non-native species, and reasons for management measures.
Coordinate rulemaking and enforcement among regulatory commissions and agencies.
GOAL 2: Identify, Designate and Protect Strategic Habitat Areas
Evaluate potential Strategic Habitat Areas by : a) coordinating, completing, and maintaining baseline habitat mapping (including seagrass, shell bottom, and other bottom types) using the most appropriate technology, b) selective monitoring of the status of those habitats, and c) assessing effects of land use and human activities on those habitats.
Identify and designate Strategic Habitat Areas using ecologically based criteria, analyze existing rules and enact measures needed to protect Strategic Habitat Areas and improve programs for conservation (including voluntary actions) and acquisition of areas supporting of Strategic Habitat Areas.
GOAL 3: Enhance Habitat and Protect it from Physical Impacts
Greatly expand habitat restoration, including: a) creation of subtidal oyster reef no-take sanctuaries and b) re-establishment of riparian wetlands and stream hydrology.
Prepare and implement a coast wide beach and inlet management plan that requires ecologically-based guidelines for minimization of impacts to fish habitat, while addressing socio-economic concerns.
Protect SAV, shell bottom and hard bottom areas from fishing gear effects through improved enforcement, establishment of protective buffers around habitats, and further restriction of mechanical shellfish harvesting.
Protect fish habitat by revising estuarine and public trust shoreline stabilization rules using best available information, considering estuarine erosion rates, and the development and promotion of incentives for use of alternatives to vertical shoreline stabilization measures.
Protect and enhance habitat for anadromous fish by: a) incorporating water quality and quantity needs of fish in surface water use planning and rule making, and b) eliminating obstructions to fish movement, such as dams, locks, and road fills.

* refer to Chapter 9 of the CHPP for full recommendation text, actions and strategies.

GOAL 4: Enhance and Protect Water Quality
Reduce point source pollution from wastewater by: a) increasing inspections of wastewater treatment facilities, collection infrastructure, and land disposal sites, and b) providing incentives for upgrading all types of wastewater treatment systems.
Adopt or modify rules or statues to prohibit ocean wastewater discharges.
Prohibit new or expanded stormwater outfalls to coastal beaches and to coastal shellfishing waters (EMC surface water classifications SA and SB) except during times of emergency when public safety and health are threatened, and continue to phase-out existing outfalls by implementing alternative stormwater management strategies.
Enhance coordination with, and financial/technical support for, local government actions to better manage stormwater and wastewater.
Improve land-based strategies throughout the river basins to reduce non-point pollution and minimize cumulative losses to wetlands and streams through voluntary actions, assistance, and incentives, including: a) improved methods to reduce sediment pollution from construction sites, agriculture, and forestry, b) increased on-site infiltration of stormwater, c) documentation and monitoring of small but cumulative impacts to wetlands and streams resulting from approved, un-mitigated activities, d) incentives for low-impact development, e) increased inspections of onsite wastewater treatment facilities, and f) increased water re-use and recycling.
Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through rule making, including: a) increased use of effective vegetated buffers, b) reduction of impervious surfaces where feasible and reduction of the level of impervious surface allowable in the absence of engineered stormwater controls, c) expansion of CAMA Areas of Environmental Concern (AECs) upstream and landward, and d) consideration of erosion rates as an additional factor in the siting of structures on estuarine and public trust shorelines.
Develop and implement a comprehensive coastal marina and dock management plan and policy to prevent closures of shellfish harvest waters and minimize cumulative impacts on fish habitats.
Reduce non-point source pollution from large scale animal operations by the following actions: a) support early implementation of environmentally superior alternatives to the current lagoon and spray field systems as identified under the Smithfield Agreement and continue the moratorium on new/expanded swine operations until alternative waste treatment technology is implemented, b) seek additional funding to phase-out large-scale animal operations in sensitive areas and relocate operations from sensitive areas, and c) use improved siting criteria to protect fish habitat.

* refer to Chapter 9 of the CHPP for full recommendation text, actions and strategies.

ADOPTION OF NORTH CAROLINA COASTAL HABITAT PROTECTION PLAN AND AGREEMENT TO PREPARE COOPERATIVE IMPLEMENTATION PLANS

The Chairmen of the North Carolina Environmental Management Commission, Coastal Resources Commission, and Marine Fisheries Commission affirm that their respective Commissions adopt the North Carolina Coastal Habitat Protection Plan, as provided in General Statute 143B-279.8.

We recognize the importance of North Carolina's coastal fisheries resources and the commercial and recreational fisheries they support. The continued existence and enhancement of these resources depend on the health of the aquatic habitats they occupy. We pledge to cooperatively manage these aquatic habitats to ensure the long-term viability of the coastal fisheries resources. We agree that these Commissions will work to accomplish the following goals:

GOAL 1 – Improve effectiveness of existing rules and programs protecting coastal fish habitats

GOAL 2 – Enhance fish habitats and protect them from physical impacts

GOAL 3 – Protect and enhance water quality

GOAL 4 – Identify, protect, and enhance all strategic habitats

By July 1, 2005, the three Commissions and the Department of Environment and Natural Resources will each prepare and adopt Cooperative Coastal Habitat Protection Implementation Plans to accomplish the goals listed above. The Implementation Plans will establish priorities and identify actions to be taken within specified time periods, including measures of success. The Department and the three Commissions will review progress annually and revise their plans at least every five years.

EXECUTIVE SUMMARY

North Carolina's coastal fisheries are among the most productive in the United States because of the wide variety of habitats available, the largest estuarine system (2.3 million acres) of any single Atlantic coast state, location of North Carolina at the transition between mid-Atlantic and south Atlantic regions, and a management system that supports active citizen participation. The condition of some important fish stocks declined during the late 1980s and early 1990s (for example, river herring, weakfish, and summer flounder) as fish kills and water-borne disease outbreaks increased. Protection and enhancement of fish habitats utilized by such species would be especially beneficial in supporting stock recovery.

Recognizing the critical importance of healthy and productive habitats to produce fish for human benefits, the North Carolina General Assembly included a provision in the Fisheries Reform Act of 1997 instructing the Department of Environment and Natural Resources (DENR) to prepare Coastal Habitat Protection Plans (CHPPs). The legislative goal of the plans is long-term enhancement of coastal fisheries associated with each habitat.

A unique feature of the plans is that three regulatory commissions (Environmental Management, Coastal Resources, and Marine Fisheries Commissions) are to adopt and implement the plans, thus requiring a coordinated management approach. The plans are to include information on the description, distribution, function, status and trends of important habitats; threats to those habitats; and recommendations to address the threats. The CHPP area includes all eight of the river basins that drain to the coast of North Carolina up to the Fall Line, which is the upper limit of migration of almost all coastal fisheries species, as well as areas that influence the health of those waters.

The DENR and Commissions began working on the plans in 1998. The comprehensive approach established by the General Assembly had never been used before in the United States, so the department tried several different approaches before deciding to use the six basic fish habitat types as the framework for the plans:

- Water column
- Shell bottom
- Submerged aquatic vegetation (SAV)
- Wetlands
- Soft bottom
- Hard bottom

Once the habitat approach had been established, the DENR and Commissions moved on to address the tasks listed in the Act. After reviewing the results of hundreds of scientific studies and input from experts and citizens alike, it became even more apparent that North Carolina's coastal fish habitats are seriously threatened by human activities, including development (urban/suburban), agriculture, forestry, transportation, channel dredging, shoreline stabilization, and marinas. The water column and shell bottom are the most threatened habitats, shell bottom because there is so little of it left, and the water column because there are so many pollution sources. The greatest single threat to North Carolina's coastal fish habitats is probably stormwater runoff, which carries sediment, wastes, and chemical pollutants into coastal waters, reducing water clarity, promoting algal blooms, decreasing dissolved oxygen, and reducing the benefits that a healthy coastal system would provide to coastal residents and visitors.

The CHPP development process identified hundreds of management needs. The three Commissions reviewed the threats, along with possible management actions to address them. The Commissions selected four general goals and a series of recommendations to reach each goal, as shown below. Implementation of these recommendations will involve new program activities and revised priorities for existing programs

within DENR and other agencies. Significant new funding is essential. Prioritization of the recommendations will occur in each Commission's implementation plan to be developed in 2005.

GOAL 1. IMPROVE EFFECTIVENESS OF EXISTING RULES AND PROGRAMS PROTECTING COASTAL FISH HABITATS

- Enhance enforcement of, and compliance with, Coastal Resources Commission (CRC), Environmental Management Commission (EMC), and Marine Fisheries Commission (MFC) rules and permit conditions.
- Coordinate and enhance water quality, physical habitat, and fisheries resource monitoring (including data management) from headwaters to the nearshore ocean.
- Enhance and expand educational outreach on the value of fish habitat, threats from human activities, effects of non-native species, and reasons for management actions.
- Coordinate rulemaking and enforcement among regulatory commissions and agencies.

GOAL 2. IDENTIFY, DESIGNATE, AND PROTECT STRATEGIC HABITAT AREAS

- Gather information to identify Strategic Habitat Areas by:
  a) Coordinating, completing, and maintaining habitat mapping (including seagrass, shell bottom, and other bottom types) using the most appropriate technology,
  b) Monitoring the status of those habitats, and
  c) Assessing effects of land use and human activities on those habitats.
- Identify and designate Strategic Habitat Areas using ecologically based criteria.
- Analyze existing rules and enact measures needed to protect Strategic Habitat Areas.
- Improve programs for conservation (including voluntary actions) and acquisition of areas supporting Strategic Habitat Areas.

GOAL 3. ENHANCE HABITAT AND PROTECT IT FROM PHYSICAL IMPACTS

- Greatly expand habitat restoration, including:
  a) Creation of subtidal oyster reef no-take sanctuaries, and
  b) Re-establishment of riparian wetlands and stream hydrology.
- Prepare and implement a coast wide beach and inlet management plan that requires ecologically based guidelines for minimization of impacts to fish habitats, while addressing socio-economic concerns.
- Protect Submerged Aquatic Vegetation (SAV), shell bottom, and hard bottom areas from fishing gear impacts through improved enforcement, establishment of protective buffers around habitats, and further restriction of mechanical shellfish harvesting.
- Protect fisheries resource habitat by revising estuarine and public trust shoreline stabilization rules using best available scientific information, considering estuarine erosion rates, and development and promotion of incentives for alternatives to vertical shoreline stabilization measures.
- Protect and enhance habitat for anadromous fishes by
  a) Incorporating the water quality and quantity needs of fish in surface water use planning and rule making, and
  b) Eliminating obstructions to fish movements, such as dams, locks, and road fills.

GOAL 4. ENHANCE AND PROTECT WATER QUALITY

Point sources

- Reduce point source pollution by:
  a) Enhancing inspections of sewage treatment facilities, collection infrastructure, and land disposal sites, and
  b) Providing incentives for upgrading all types of wastewater systems.
- Amend rules to prohibit ocean wastewater discharges.
- Prohibit new or expanded stormwater outfalls to coastal beaches and to coastal shellfishing waters (EMC surface water classifications SA and SB) and continue to phase-out existing outfalls by implementing alternative stormwater management strategies.

Non-point sources

- Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through voluntary actions, Best Management Practices (BMPs) and incentives, including:
  a) Improved methods for reducing sediment pollution from construction sites, agriculture, and forestry;
  b) Increased on-site infiltration;
  c) Documentation and monitoring of small but cumulative impacts to wetlands and streams resulting from un-permitted/un-mitigated activities;
  d) Incentives for low impact development;
  e) Enhanced inspections of onsite wastewater treatment facilities;
  f) Increased water re-use and recycling.
- Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through rule making, including:
  a) Larger vegetated buffers,
  b) More stringent impervious surface limits,
  c) Expansion of Areas of Environmental Concern (AECs) upstream and landward,
  d) Establishment of setbacks along estuarine and public trust shorelines.
- Develop and implement a comprehensive coastal marina and dock management plan and policy to prevent closures of shellfish harvest waters and cumulative impacts to fish habitats.
- Reduce non-point source pollution from animal operations by the following actions:
  a) Continue the moratorium on new/expanded swine operations until alternative waste treatment technology is implemented,
  b) Use a greater percentage of agricultural conservation funds to phase-out or re-locate concentrated animal operations in sensitive areas,
  c) Mandate the phase-out of waste lagoons by a specific deadline,
  d) Use improved siting criteria to protect fish habitats.

CHAPTER 1. INTRODUCTION

1.1. PUBLIC TRUST DOCTRINE

North Carolina state government applies the Public Trust Doctrine in management of its coastal lands, surface waters, and the resources in those waters. The Public Trust Doctrine states that "public trust lands, waters, and living resources in a State are held by the State in trust for the benefit of all the people, and establishes the right of the public to fully enjoy public trust lands, waters, and living resources for a wide variety of recognized public uses. The doctrine also sets limitations on the States, the public, and private owners, as well as establishing the responsibilities of the States when managing these public trust assets" (Coastal States Organization, Inc. 1997).

The Constitution of North Carolina implements the Public Trust Doctrine in Article XIV, Section 5, which states: "It shall be the policy of this State to conserve and protect its lands and waters for the benefit of all its citizenry, and to this end it shall be a proper function of the State of North Carolina and its political subdivisions to acquire and preserve park, recreational, and scenic areas, to control excessive noise, and in every other appropriate way to preserve as a part of the common heritage of this State its forests, wetlands, estuaries, beaches, historical sites, open lands, and places of beauty."

Public trust resources include the waters to the upstream extent of navigation, including navigation by small recreational boats, such as canoes or kayaks [North Carolina Supreme Court (*Gwathmey v. State of North Carolina*, 342 N.C. 287, 464 S. E. 2d. 674, 1995)]; submerged lands beneath the waters up to the normal high tide line (or normal water level in areas not subject to lunar tides); and the fisheries resources within those waters (see definition below). Common public trust uses include navigation and commerce, fishing, bathing (swimming), and hunting. Under certain circumstances, private entities may own submerged lands, but public trust rights in the waters over those lands are not affected by such ownership.

The State can restrict exercise of public trust rights in the overall public interest. Such restrictions can be in the form of laws enacted by the North Carolina General Assembly or rules adopted as part of the North Carolina Administrative Code (NCAC) by regulatory commissions established by the General Assembly. A variety of regulatory commissions and administrative agencies established by the General Assembly has authority for management of North Carolina's coastal lands, waters, and fishes under state and federal laws. State authority generally applies within the boundaries of North Carolina, which extends from internal waters (creeks, rivers, and lakes) downstream through the coastal sounds, and into the Atlantic Ocean for three nautical (nm) or 3.45 statute miles from the state's Atlantic Ocean shoreline. Federal jurisdiction applies from that point out to 200 nm (230.16 statute miles) from shore, an area called the Exclusive Economic Zone (EEZ). Several state and federal agencies conduct major regulatory, research, and educational programs that affect North Carolina's coastal fisheries resources and their habitats (Appendix A).

1.2. THE FISHERIES REFORM ACT AND COASTAL HABITAT PROTECTION PLANS

The North Carolina Fisheries Reform Act of 1997 (FRA – S.L.1997-400, H.B. 1097) includes a provision [General Statute (G.S.) 143B-279.8] for preparation of Coastal Habitat Protection Plans (CHPPs) by the North Carolina Department of Environment and Natural Resources. This section of the FRA resembles the federal Magnuson-Stevens Fishery Conservation and Management Act reauthorization of 1996 [also known as the Sustainable Fisheries Act (SFA)]. The SFA requires the regional fishery management councils and National Marine Fisheries Service (NMFS) to amend federal fishery management plans to include provisions for the protection of "Essential Fish Habitat" (EFH) from federally funded activities. ***The legislative goal of the CHPPs is long-term enhancement of coastal fisheries associated with coastal habitats.*** The CHPP is to identify threats and recommend management actions to protect and restore

habitats critical to North Carolina's coastal fishery resources. The plans must be adopted by the Coastal Resources (CRC), Environmental Management (EMC), and Marine Fisheries (MFC) commissions. Once adopted, the plans will help to ensure consistent actions among commissions, as well as their supporting Department of Environment and Natural Resources (DENR) agencies. The passage of the FRA and the initiation of the CHPP program demonstrated the public desire and political will to better manage North Carolina's coastal fishery habitats.

Since the mid-1980s, the State of North Carolina, through the Governor and General Assembly, has convened several high level panels to examine coastal environmental and fishery management issues. Each has made numerous policy recommendations concerning improved management of fish habitat and water quality.

- The Albemarle-Pamlico Estuarine Study (1987 – 1994) recommended numerous water quality, fishery management, and land use reforms in its Comprehensive Conservation and Management Plan, including retain, restore, and enhance water quality; conserve and protect vital fish and wildlife habitats; and restore or maintain fisheries (Waite et al. 1994).
- The North Carolina Coastal Futures Committee was established in recognition of the 20th anniversary of passage of the Coastal Area Management Act (CAMA), which established North Carolina's coastal zone management system under the CRC. The Committee's report cited the tremendous growth in population and use of coastal resources, and recommended a number of important actions, including restoration and protection of important fisheries habitats, the need to address nonpoint source pollution, restoration of impaired coastal waters, and protection of freshwater wetlands similar to existing protection of coastal wetlands (North Carolina Coastal Futures Committee 1994).
- The Blue Ribbon Advisory Council on Oysters recommended a major increase in planting of oyster cultch to help restore oyster resources as well as changes in management of oyster culture practices (Frankenberg 1995).
- Most of the recommendations of the Fisheries Moratorium Steering Committee were included in the FRA in 1997, including development of this CHPP. The report also recommended reform of North Carolina's coastal fisheries management system, based on use of state Fishery Management Plans (FMPs) (MSC 1996).
- The CRC convened the Estuarine Shoreline Protection Stakeholders in 1999 to examine impacts of estuarine shoreline uses and water quality. The group's report included comprehensive recommendations to improve agency coordination, enhance basinwide water quality management, restoration of impaired waters, and reduction of point and nonpoint source pollution (North Carolina Estuarine Shoreline Stakeholders 1999).

Thus, there is a rich history of citizen participation in examination of coastal habitat and water quality issues in recent years. Based on public comments at 10 public CHPP meetings along the coast and inland during the summer of 2003 (Miller 2004), there is also considerable frustration that many, repeated recommendations have not been implemented. Because the CHPP uniquely brings together three major regulatory commissions, there is an expectation that positive actions will result from this effort.

While the MFC manages commercial and recreational fishing practices in coastal waters through rules implemented by the Division of Marine Fisheries (DMF), several other agencies directly and indirectly affect coastal fisheries and fish habitats. The EMC has wide-ranging authority over activities affecting water quality statewide. Rules adopted by the EMC govern point and nonpoint discharges, wastewater management, alteration of non-coastal wetlands, and stormwater management. The EMC is unique because its rules are implemented by several different DENR agencies, including the Division of Water Quality (DWQ), Division of Air Quality (DAQ), Division of Water Resources (DWR), and the Division of Land Resources (DLR). The DLR is also unique because it administers rules adopted by multiple regulatory commissions, including EMC, Sedimentation Control Commission, and the Mining

Commission. The CRC enacts rules to manage development and land disturbing activities along estuarine and ocean shorelines, shoreline stabilization, alteration of submerged bottoms and coastal wetlands, and marina construction. The Division of Coastal Management (DCM) implements rules adopted by the CRC. The North Carolina Wildlife Resources Commission (WRC) has a direct role in the management of fisheries through the designation of primary nursery areas in Inland Waters and, including many anadromous fish spawning areas, and regulation of fishing in those waters. There are a myriad of other state, federal, and interstate programs affecting coastal fisheries habitat in North Carolina (Appendix A).

This CHPP was written by DMF staff with assistance from the CHPP Development Team - scientists and planners from DMF, DCM, DWQ, Division of Environmental Health (DEH), and WRC (Appendix B). An Intercommission Review Committee (IRC), consisting of two members from each of the three commissions (Appendix B), provided policy oversight, reviewed this plan, and developed the management recommendations (Chapter 9.0).

1.3. PURPOSE AND ORGANIZATION OF DOCUMENT

The primary focus of this plan is habitats for coastal fisheries resources in eastern North Carolina, threats to those habitats, and management actions to address those threats. The CHPP identifies four goals for protection of coastal fisheries habitat:

1) Improve effectiveness of existing rules and programs protecting coastal fish habitats
2) Identify, designate, and protect all Strategic Habitat Areas
3) Enhance habitat and protect it from physical impacts
4) Enhance and protect water quality

The CHPP is built around six basic habitats utilized by coastal fishery species: water column, shell bottom, submerged aquatic vegetation (SAV), wetlands, soft bottoms, and hard bottoms. Within each of the following habitat chapters, there is detailed information on the habitat's description, distribution, ecological role and functions for finfish and shellfish species (primarily fishery species, but also forage and protected species), status and trends, threats, and management needs. The term "management" is defined broadly to include regulatory, enforcement, research, monitoring, and restoration activities affecting coastal fish habitat. Management needs are based on documented inadequacies in the current management framework and are highlighted in the habitat chapters with *italics*. A summary highlighting the most pressing management needs is provided at the end of each habitat chapter. A chapter (8.0) addressing strategic habitats (what they are and criteria for their designation) follows the habitat chapters. The final chapter lists the most pressing management recommendations as developed by the IRC. Each of the Commissions will use the threats, management needs, and recommendations to develop coordinated coastal habitat management strategies as provided in the Act. The DENR will also develop a coordinated strategy to implement the CHPP recommendations.

1.4. AREA DESCRIPTION

The CHPP area includes all waters flowing into North Carolina's coastal waters and the watersheds they drain. Table 1.1 shows that the CHPP area is approximately 12% water (3,181,881 acres) and 88% land (24,229,770 acres). Maps 1.1a and 1.1b show this area, including water bodies, the main towns, roads and other local and regional features noted throughout the CHPP. Local and regional differences in habitat and associated fish species are determined by climate, geology, ground water and surface water hydrology, land use, and associated human population.

Table 1.1. The land and water areas for each North Carolina Coastal Habitat Protection Plan Management Unit. *(Source: 1:100,000 scale USGS topographic quadrangle maps)*

Management Unit	Land area		Water area		Total area
	Acres	% of total	Acres	% of total	(acres)
Albemarle	1,669,684	72	658,400	28	2,328,084
Cape Fear	5,795,998	99	64,973	1	5,860,970
Chowan	3,183,877	98	51,691	2	3,235,568
Coastal Ocean	15,374	2	724,842	98	740,216
Core/Bogue	188,976	53	167,998	47	356,974
Neuse	3,466,244	96	135,571	4	3,601,815
New/White Oak	481,345	93	38,449	7	519,794
Pamlico Sound	394,337	27	1,061,613	73	1,455,950
Roanoke	6,118,980	98	140,827	2	6,259,807
Southern Estuaries	253,227	95	14,425	5	267,652
Tar/Pamlico	2,661,729	96	123,092	4	2,784,821
Total	**24,229,770**	**88**	**3,181,881**	**12**	**27,411,651**

To address local and watershed issues, the CHPP program will also produce individual Management Unit (MU) plans (after the CHPP development) based primarily on the same watershed boundaries used by DWQ for Basinwide Water Quality Plans. Since the CHPP is focused on fish and fisheries, some minor boundary changes were made to reflect similarities in fish habitats, or in estuarine and coastal water body dynamics. A watershed approach is necessary because many fisheries rely on the interconnectivity of waters within a watershed, and most pollutants are conveyed into estuarine waters via upstream conduits, such as rivers and streams. The eleven MU areas and their boundaries approved by the IRC are shown on Map 1.2. The units are Chowan, Albemarle, Roanoke (River), Pamlico Sound, Tar-Pamlico, Neuse, Core/Bogue, New-White Oak, Cape Fear, Southern Estuaries, and Coastal Ocean. Most of the Chowan and Roanoke River MUs, and part of the Albemarle MU, are located in Virginia. The Coastal Ocean MU includes North Carolina's territorial waters and ocean front beaches. Among MUs, the largest area of water (1,061,613 acres) is in Pamlico Sound, and the smallest area (14,425 acres) is in the Southern Estuaries (Table 1.1).

Climate and weather

Weather conditions, especially temperature, precipitation, wind, and storms, exert major influences on North Carolina's coastal area and the fishery resources of eastern North Carolina. The climate along the North Carolina coast is strongly influenced by the Atlantic Ocean. North Carolina's coastal ocean includes the convergence between two major oceanic currents: the warm, north-flowing Gulf Stream and the cool, south-flowing Virginia coastal current (also called the Labrador Current). The Gulf Stream current moves within 10 – 12 mi (16.1 – 19.3 km) of the coast at Cape Hatteras before turning northeast toward Europe, bringing southern species (such as brown, white, and pink shrimp; king and Spanish mackerel; snappers and groupers; and calico scallops) to North Carolina's waters. The Virginian (Labrador) Current ends at the Gulf Stream, supplying northern oceanic species (such as Atlantic mackerel, Atlantic herring, and Atlantic cod) to North Carolina.

The work of Orlando et al. (1994) closely examined coastal wind patterns. These winds vary at basically three time scales: seasonal (>1 month), synoptic (3-20 days) due to the passage of weather systems; and diurnal (<1 day) due to changes in local sea breezes. Seasonal winds blowing in the South Atlantic Bight (SAB) (area from Cape Hatteras, N.C. to Cape Canaveral, Fla.) originate either from the Bermuda-Azores High in the North Atlantic or from a smaller high pressure area centered over the Ohio Valley (Ohio Valley High). During winter (November – February), winds flowing from the northwest gradually shift to the north. Winds are stronger in North Carolina than in states to the south during this season. During

spring, the dominant influence of the Ohio Valley High is replaced by the Bermuda - Azores High, resulting in winds from the west and southwest. West and southwest winds cause offshore movement of surface water and inshore movement of bottom water along much of the North Carolina coast, resulting in upwelling in some near-shore areas. Autumn winds (September – October) flow more from the northeast.

Storms can have a significant impact on the geology of the coastal area. Tropical storms can bring storm surges over 16 ft (4.9 m) above sea level along the south Atlantic coast (VIMS 1974 in Orlando et al. 1994), causing coastal flooding. Between 1950 and 1996, 14 hurricanes struck the North Carolina coast. More recently, hurricanes Bertha and Fran hit North Carolina in 1996. In 1997 and 1998, two more hurricanes affected the coastal area: Danny in July 1997 and Bonnie in August 1998. Three sequential storms affected the North Carolina coast during late August - October 1999 (Hurricanes Dennis and Floyd, and Tropical Storm Irene), inundating the region with up to 3.3 ft (1m) of rainfall, resulting in several weeks of flooding and major environmental and economic damage (Bales et al. 2000; Paerl et al. 2001). Similarly, "nor'easter" storms during fall through spring also cause coastal flooding. For example, the Good Friday storm of 1962 was one of the most severe storms recorded to strike the United States' Atlantic coast, causing severe damage from North Carolina to New England.

Geology and hydrology

A chain of low-lying barrier islands extending from Virginia to Cape Fear dominates the geology and surface water hydrology of North Carolina's ocean coastline. Artificial barrier islands extending from the Cape Fear River to South Carolina were created by dredging the Atlantic Intracoastal Waterway (ICW) in the 1930s (Map 1.1b). The northern part of the natural barrier islands, the Outer Banks, separates the Albemarle/Pamlico sounds complex from the coastal ocean. Proceeding inland, eastern North Carolina's land area is divided between the Coastal Plain and Piedmont physiographic regions, with the majority of land in the Coastal Plain. These two regions are separated by the Fall Line (Map 1.3), where streams are characterized by falls and rapids. The Coastal Plain region extends from the seashore up to the Fall Line and varies in width from 120 to 160 mi (193.1 – 257.5 km). Streams in the western Coastal Plain have sandy bottoms. Going east, those sandy bottoms change to mud and clay in the eastern Coastal Plain, where there are extensive swamps and occasional large, shallow lakes (Menhinick 1991). The streams converge near the coast to form estuaries where fresh water mixes with salt water from the ocean. The Chowan, Roanoke, Tar-Pamlico, and Neuse rivers flow into the Albemarle-Pamlico estuarine system, the second largest estuary on the U.S. Atlantic coast. The Cape Fear River flows directly into the Atlantic Ocean.

The groundwater hydrology of coastal North Carolina is dominated by six major aquifers: the surficial, Yorktown, Black Creek, Castle Hayne, Cretaceous, and Peedee (Steel 1991; Giese et al. 1997). The various aquifers intersect the surface in zones running northeast to southwest. The Cretaceous aquifer is the most extensive and farthest west of Coastal Plain aquifers. The surficial and Yorktown are farthest east, and the Castle Hayne lies between the Yorktown and Cretaceous. The thickness of the aquifers varies from a several feet along the fall line, to more than 3000 m (9843 ft) at Cape Hatteras (Steel 1991).

Land use and human population

Estuarine and coastal areas contain some of the nation's most densely populated and rapidly growing areas (Beach 2002). Population density patterns reflect historical development and population pressures, location relative to transportation networks, and the natural resources of the coastal areas (NOS 1990). As population density increases, so does the potential for degradation of the natural environment by human activities (Cairns and Pratt 1992). In the year 2000, New Hanover County had the highest population density (803 persons/mi^2, Table 1.2) among the 20 coastal counties included in the Coastal Area Management Act (CAMA). Onslow, Pasquotank, Craven, Carteret, and Brunswick counties also had relatively high population densities (over 100 persons/mi^2).

Table 1.2. Human population, density, and growth in Coastal Plain counties of North Carolina sorted by Coastal Area Management Act (CAMA) counties and other Coastal Plain counties, and growth during 1990 – 2000. *(Source: North Carolina Office of State Budget and Management, 2002.)*

However, the highest-density areas in North Carolina were in the Piedmont region (Map 1.4), suggesting that at least some of the problem from highly mobile pollutants may be traced upstream. The lowest population densities in eastern North Carolina (about 10 persons/mi^2) were in Tyrrell and Hyde counties.

The human population of North Carolina's coastal area is growing rapidly. During the 1970s, counties within the Albemarle-Pamlico region grew at a rate below the statewide average, but in the 1980s, those counties exceeded the statewide average growth rate by 3.6% (Steel 1991). Growth rates were highest in oceanfront counties, except Hyde, in which all the oceanfront property is federally owned (Ocracoke

Island lies within Cape Hatteras National Seashore). Combined population growth in the eight counties bordering the Atlantic Ocean (Currituck, Dare, Hyde, Carteret, Onslow, Pender, New Hanover, and Brunswick) has exceeded 20% per decade since 1970 (North Carolina State Library, <http://data.osbm.state.nc.us/pls/linc>, 24 September 2003). During that period, population changes in those counties ranged from an increase of 91% (Dare County from 1970 to 1980) to a loss of 8% (Hyde County from 1980 to 1990). North Carolina's 44 Coastal Plain counties had a 16% population increase from 1990 to 2000 (1,919,186 to 2,229,888), compared to a 19% increase in non-Coastal Plain counties for the same time period. However, there was great variation among counties in the Coastal Plain (Map 1.5). As shown in Table 1.2, New Hanover, Pender, Currituck, Dare, and Brunswick counties had growth rates ranging from about 32 to 44%, while Onslow, Hertford, Washington, and Bertie counties had very low or negative growth rates (-3 to 1.3%).

The coastal counties of North Carolina experience tremendous seasonal population fluctuations due to the influx of tourists. The seasonal population of coastal cities and towns increased, on average, 54% from 1990 to 2000 (Table 1.3). These estimates do not include day visitors who come to the area, but do not stay overnight. The counties that border the ocean and sounds have the greatest population fluctuations due to tourism. In many of these counties, public facilities, including wastewater treatment, roads, and water supply systems, are being taxed to the limit (Steel 1991).

As population increases, so does the need for infrastructure (roads, schools, water and sewer facilities, electric transmission lines, etc.) to support those people, sometimes resulting in loss of important habitats and supporting areas, such as wetlands and riparian forests (see Water Column and Wetland chapters for more information on changes in land cover). Land cover data reported by the federal National Resource Inventory (D. Good, U.S. Department of Agriculture, Natural Resource Conservation Service, pers. com., 2001) show that urban/built-up land increased in coastal river basins by 83% from 1982 to 1997 (Appendix C and D).

Despite the growth in urban/built-up areas, land cover in coastal North Carolina is still primarily forest (53%) and cultivated crops (21.5%) (Appendix D). Beach (2002) showed that increases in developed areas have far outpaced population growth in coastal areas nationwide, resulting in a greater habitat impact than population data alone suggest. Beach (2002) concluded that conversion of land in the coastal zone from open space (forest and agricultural uses) to urban/suburban uses was the primary threat to coastal water quality. As of 1997, urban/built-up land covered 2.9-19.6% of the land area in North Carolina's coastal river basins (Appendix D).

Virtually all licensed commercial fishermen in North Carolina participate in several different fisheries during the course of a year [an "annual round" of work that, in total, provides for a year's employment and income (Johnson and Orbach 1996)]. Few can count on a full year's work in a single fishery. Most fishermen own a variety of fishing gears, and many own several vessels, each rigged for different fisheries. The nature of the target species (growth, seasonal migrations), weather variations, rule changes and restrictions, and other variables require that successful commercial fishermen exhibit great adaptability. Many fishermen hold non-fishing jobs as part of their annual work cycle. In fact, some persons with a commercial fishing heritage, who make very little money from commercial fishing, instead earning most of their income in non-fishing occupations, consider themselves to be commercial fishermen.

Recreational fishing is very important economically and culturally in coastal North Carolina. Hook and line fishing has been popular for generations. There are records of surf fishing from the early colonial period. Surf fishing along the Outer Banks for red drum and bluefish was the subject of articles in sporting magazines in the 1930s (Godwin et al. 1971). Tens of thousands of private recreational boaters fish the coastal waters, while thousands more fish from the shore, piers, and other structures. Since 1997, about 1.6 million anglers (64% non-residents) have made about 5.4 million fishing trips each year in coastal North Carolina. Diaby (1997) estimated that sport fishing contributed almost $75 million to the Carteret County economy, supporting over 1,800 jobs.

Protected species

North Carolina state law [G.S. 113-331] protects endangered, threatened, and special concern species of mammals, birds, reptiles, amphibians, freshwater fishes, and freshwater and terrestrial mollusks under the jurisdiction of the North Carolina Wildlife Resources Commission (Appendix E). The North Carolina Natural Heritage Program (NHP) lists seven marine and estuarine fishes. The shortnose sturgeon (*Acipenser brevirostrum*) is listed as endangered at the state and federal levels. The Atlantic sturgeon (*Acipenser oxyrhynchus*) is listed as Special Concern for state and federal protection. An MFC rule [15A NCAC 3M .0508] prohibits possession of any sturgeon in North Carolina's coastal waters. There are five marine and estuarine fishes listed as significantly rare: spinycheek sleeper (*Eleotris pisonis*), lyre goby (*Evorthodus lyrinus*), marked goby (*Gobionellus stigmaticus*), freckled blenny (*Hypsoblennius ionthas*), and opossum pipefish (*Microphis brachyurus*). All five of these species occur in marine and estuarine systems of the Cape Fear MU. Shortnose and Atlantic sturgeon occur in riverine, estuarine and marine systems of the CHPP management area. Other marine and estuarine species listed by NHP include Florida manatee (*Trichechus manatus*), loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas*), hawksbill sea turtle (*Eretmochelys imbricata*), leatherback sea turtle (*Dermochelys coriacea*), and Kemp's ridley sea turtle (*Lepidochelys kempii*). There are also numerous birds, reptiles, and mammals listed by NHP associated with salt marshes and other coastal wetlands [(LeGrand and Hall 1999 (NHP animals); Amoroso 1999 (NHP plants)]. Listed estuarine species include the Carolina diamondback terrapin (*Malaclemys terrapin centrala*), Carolina salt marsh snake (*Nerodia sipedon williamenglelsi*), while the federally-listed piping plover (*Charadrius melodus*) occurs along ocean beaches and near inlets.

In addition to species listed by NHP, there are also species designated for protection under the Marine Mammal Protection Act (for example, bottlenose dolphin, *Tursiops truncatus*). Several species of marine mammals regularly utilize North Carolina's nearshore ocean waters as migratory corridors or nursery and feeding grounds. Northern right whales (*Balaena glacialis*), one of the world's most endangered species, pass by on their annual migrations between winter calving grounds along the Georgia coast and summer feeding areas from Cape Cod to the Bay of Fundy. Similarly, humpback whales (*Megaptera novaenagliae*) pass by offshore North Carolina during their annual journey between North Atlantic feeding grounds and winter calving areas off Hispañola. Bottlenose dolphin are year-round residents of the coastal ocean waters of North Carolina, and they utilize much of the estuarine system during the warmer months, going as far upstream as the lower Neuse River. Harbor porpoise (*Phocoena phocoena*) spend a part of each winter off the Outer Banks, as far south as Hatteras Bight, below Diamond Shoals. A number of other marine mammals occasionally utilize North Carolina's coastal waters, including pygmy sperm whales (*Kogia breviceps*) and pilot whales (*Globicephala melaena*).

1.5. STATUS OF FISHERIES

The current status of fisheries may be an indicator of the potential impacts of habitat degradation and loss. The status of North Carolina's coastal fishery resources is evaluated every year by DMF. Several pertinent definitions are provided for terms used in this section.

- Stock (<http://www.ncdmf.net/resource.htm>, 2002): A stock is a group of genetically similar fish that behave as a unit. Determining stock status requires long-term collection and subsequent analysis of data such as length, weight, age, catch, fishing effort, spawning stock biomass, juvenile abundance indices, and fishing mortality. All data are not available for all species, and there is no single measure or simple index that, by itself, describes the status of a given stock. Further, information from a single year does not indicate stock status. Therefore, the stock status assigned for each coastal fishery stock is based on the available time-series of data.
- Fishery Management Plan (FMP): Plan for achieving specified management goals for a fishery. It includes data, analyses, and management measures for a fishery. The process for preparing FMPs in North Carolina was established by the FRA [G.S. 113-182.1]. The FRA states:

"[t]he goal of the plans shall be to ensure the long-term viability of the State's commercially and recreationally significant species and fisheries…Each plan shall:

a. Contain necessary information pertaining to the fishery or fisheries, including… fishery habitat and water quality considerations consistent with Coastal Habitat Protection Plans …"

- Stock status descriptors used by DMF (<http://www.ncdmf.net/resource.htm>, 2003):
  - **Viable**: Viable stocks exhibit stable or significantly increasing trends in average length and weight, catch-per-unit-effort (CPUE), spawning stock biomass, juvenile abundance indices based on historical averages, stable age structure that includes representatives of the older age classes, and stable or declining trends in fishing mortality.
  - **Recovering**: Recovering stocks are those stocks previously listed as Overfished or Concern that show marked and consistent improvement in the criteria listed for a Viable stock. A recovering stock may still be Overfished but would show measurable and consistent improvement toward the target(s) established in the applicable FMP.
  - **Concern**: Stocks designated as Concern are those for which an assessment is incomplete or unavailable, but data show increased effort and landings, and/or a truncated age distribution. The nature of a given fishery may also be a reason for concern (such as the roe fishery for striped mullet). Stocks especially affected by diseases or adverse natural events may also fall into this category (for example, oysters). Species designated Concern may be reasonable candidates for FMP development if the concern is well-documented and justified.
  - **Overfished**: Overfished stocks are classified based on stock assessments conducted by the DMF or some other recognized fisheries management authority. Species designated as Overfished are priority candidates for FMP development.
  - **Unknown**: Stocks for which insufficient data are available to conduct a scientifically valid stock assessment are classified as Unknown. When data for species that have been designated Unknown are subsequently collected in DMF sampling programs and analyzed, a different status may be assigned.

Based on a combination of fishery landings and value, dependence (or association) of the stock on specific habitats, and importance of management and environmental issues associated with the fisheries, the primary coastal fisheries species in North Carolina and their status are listed in Table 1.6 (<http://www.ncdmf.net/resource.htm>, 2003). Of the more than 25 species and at least 24 fish stocks listed in Table 1.6, eight stocks are Viable (33%), two are Recovering (8%), eight are Concern (33%), three are Overfished (13%), and three are Unknown (13%). The status of most stocks has been evaluated since 1997. Some stocks have shown signs of improvement from 1997 to 2003, while others have declined (Table 1.7). For example, southern flounder status has gone from Viable in 1998, to Concern from 1999 to 2001, to Overfished in 2002 and 2003. Bay scallop status has also declined from Viable (1997-1999) to Concern (2000-2003). There have also been some improvements in stock status; summer flounder, weakfish, and Albemarle Sound striped bass have gone from Concern to Viable. For more information on the status of individual fishery species, see the DMF website (<http://www.ncdmf.net/stocks/index.html>).

Table 1.6. Average fisheries landings, fishery management plan (FMP) authority, stock status, and importance in Coastal Habitat Protection Plan management units in coastal North Carolina. *(Sorted by descending commercial fisheries landings. Source: Division of Marine Fisheries commercial and recreational fisheries landings data.)*

Spot							
Spotted seatrout							
Striped bass (Albemarle Sound)							
Striped bass (except Ocean and Albemarle Sound)							
Striped bass (Ocean)							
Striped mullet							
Summer flounder							
Weakfish							

While much of the concern over declining fish stocks has been attributed to overfishing, habitat loss and degradation also make a stock more susceptible to overfishing. The effect of habitat loss and degradation could also be indicated by the lack of recovery of certain stocks after fishing pressure is reduced. For example, river herring stocks have not recovered despite reduced fishing effort in recent years. Although the role of environmental factors in the river herring decline are uncertain, the center of river herring abundance (Chowan and Roanoke rivers) has suffered from water quality problems since the 1970s.

A number of species/fisheries with high landings are not discussed because they occur primarily outside the areas emphasized in the CHPP program, such as wahoo, tunas, and dolphin, all of which live their entire lives in the ocean. Among MUs, the primary fisheries vary according to the range of salinity present. For example, Table 1.6 shows that the primary fisheries in low salinity estuaries (Albemarle, Chowan, and Roanoke MUs) include river herring, catfishes (*Ictalurus* and *Ameiurus*), striped bass, white perch (*Morone americanus*), American eel, and American shad. In areas with moderate salinities (Neuse, Tar-Pamlico, and Pamlico Sound MUs), species such as blue crab, shrimp, and spot are dominant. In higher salinity estuaries (i.e., Core/Bogue) and the near shore ocean, the primary fisheries include Atlantic menhaden, flounders, hard clams, and shrimp.

1.6. HABITAT CONCEPTS AND TERMINOLOGY

The following habitat chapters contain numerous technical terms and acronyms that may not be familiar

to the average reader. A complete list of terms and acronyms is found in Appendix F.

Habitat is simply the place where an organism lives (Odum 1959). Fish Habitat (FH) is hereby defined as freshwater, estuarine, and marine areas that support juvenile and adult populations of economically important fish species (commercial and recreational), as well as forage species important in the food chain. Fish habitat also includes land areas that are adjacent to, and periodically flooded by, riverine and coastal waters. Fish occupy specific areas or sites where the conditions are suitable for growth, protection, and/or reproduction. A species' use of specific areas can depend on various factors, including life stage, time of day, and tidal stage. Together, these habitat areas form a functional and connected system that supports the fish from spawning until death.

The upstream boundary of coastal fish habitat in North Carolina is approximately the Fall Line separating the Coastal Plain and Piedmont physiographic regions (Map 1.3) because only one coastal migratory species (American eel, *Anguilla rostrata*) has been reported significantly above the Fall Line (Menhinick 1991). Within North Carolina's coastal ecosystem, six habitat types were distinguished based on similar physical properties, ecological functions, and habitat requirements for living components:

- Water column: The water covering a submerged surface and its physical, chemical, and biological characteristics.
- Soft bottom: Areas of primarily unvegetated, unconsolidated sediment (particles smaller than rocks) beneath the water column, and not within other categories defined below.
- Submerged aquatic vegetation (SAV): Bottom recurrently vegetated by living structures of submerged, rooted vascular plants, (including roots, rhizomes, leaves, stems, propagules), as well as temporarily unvegetated areas between vegetated patches.
- Shell bottom: Intertidal or subtidal bottom composed of shell concentrations, including living oysters (*Crassostrea virginica*), hard clams (*Mercenaria mercenaria*), or other shellfish (such as whelks). Also referred to as oyster bars, oyster beds, oyster rocks, oyster reefs, clam beds, and shell hash.
- Hard bottom: Exposed areas of rock or consolidated sediments that may or may not be characterized by a thin covering of live or dead animals, generally located in the ocean rather than an estuary.
- Wetlands: Section 404 of the Federal Water Pollution Control Act defines wetlands as: "areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in wet soil conditions." The CHPP will focus primarily on wetlands that are connected to coastal water bodies by surface water of sufficient depth to allow fish utilization. These "connected" wetlands are termed "riparian wetlands" in the CHPP because they border streams and other water bodies.

North Carolina's coastal fishery resources (the "fish") exist within a system of interdependent habitat types that provide the basis for long-term fish production available for use by people (the "fisheries"). The integrity of the entire system depends upon the health of areas and individual habitat types within the system. The areas that contribute most to the integrity of the system are another category of habitat termed Strategic Habitat Area. Strategic Habitat Areas (SHAs) are hereby defined as specific locations of individual fish habitat or systems of habitat that have been identified to provide critical habitat functions or that are particularly at risk due to imminent threats, vulnerability, or rarity. Criteria for delineation of SHAs are included in chapter 8.0 (Strategic Habitat Areas). The designation of SHAs is primarily reserved for the CHPP Management Unit plans.

Ecological role and functions

The ecological role of each habitat is discussed in the habitat chapters that follow in terms of productivity

and effect on overall water quality and quantity in an ecosystem. That discussion is followed by information on specific fish habitat functions. The general functions of habitat for fishery and forage species are grouped into the following categories:

- Refuge: Properties of the habitat that provide cover for organisms at various life stages to escape from predators and adverse environmental conditions. Structural refuge can also encourage attachment of colonizing sessile (stationary or non-mobile) organisms.
- Spawning: Properties of the habitat that provide the necessary conditions (substrate, temperature, flow, structure, etc.) for successful spawning of adults.
- Nursery: Properties of the habitat that provide a combination of refuge and foraging habitat resulting in successful development of subadult life stages of aquatic organisms. Nursery habitat can be further defined as habitats that contribute disproportionately to the production of individuals that recruit to adult populations (Beck et al. 2001).
- Foraging: Properties of the habitat that enhance growth of species' life stages through the presence, accessibility, and vulnerability of prey organisms.
- Corridor: Properties of the habitat that allow relatively safe passage (either active or passive) of species' life stages among foraging, spawning, and refuge areas. This function also addresses the connectivity of aquatic habitat and its effect on aquatic organisms.

Spatial scales

In ecological terms, spatial scales are differentiated by the variable resolution of landscape features (such as a forest to a tree to an individual branch) and the manifestation of different biological, chemical, or physical patterns at those resolutions. For example, individual oyster shells, the spaces between them, and the water surrounding them could define a very fine scale. Small organisms relate to these crevices by selecting them over the surrounding unstructured bottom. The small organisms are relatively separate from what is happening in the entire watershed, although watershed patterns can affect them through the surrounding water. The entire watershed occupies a much larger scale in which anadromous fish, for example, require different areas depending on time of year and life stage. Regional scales encompass multiple watersheds and affect individual watersheds with similar climatic patterns and other large-scale phenomena. Highly migratory organisms like tunas, whales, and sea birds relate to habitat at regional scales while at the same time selecting fine-scale habitat characteristics at any specific point in time. There are basically three larger scales used to describe habitat and ecosystem organization and function in this document: regional, watershed, and site-specific.

- Regional scale is defined by large biogeographic regions, such as the mid-Atlantic and South Atlantic Bights or the Coastal Plain and Piedmont physiographic regions of eastern North America.
- Watershed scale is defined by CHPP management units or by other hydrologic units based on DWQ or U.S. Geological Survey (USGS) delineations. Nationally, the typical watershed covers 40,000 to 250,000 acres (USGS 2001).
- Site-specific scale is defined by DWQ as water bodies delineated on 1:24,000 scale hydrographic maps or by features named on NOAA nautical charts. Within a given area, a given habitat type may be dominant, but not continuous, such as patchy distribution of SAV. Specific habitat features change continually, especially at their edges. Beds of SAV expand and contract. Thus there is a high degree of natural variability within habitats.

Impacts, sources, and threats

Coastal fisheries resources in North Carolina have evolved over geologic time to live within their existing conditions. Thus, they have adapted to the gradual climate shifts and episodic storm events that have occurred through time. But these natural and gradual changes did not include the host of artificial chemicals, deforestation of riparian lands, stormwater runoff, nutrient enrichment, destruction of habitats, and highly effective fishing practices that have developed during the last century, and are so pervasive

today. These threats to coastal fish habitat can be characterized by impacts types and sources.

Impacts are specific effects on habitat such as extremely low flow, nutrient enrichment, or erosion. These impacts have corresponding effects on living resources, which can be both positive and negative. Positive impacts can result from habitat preservation, enhancement, and restoration efforts. Negative impacts can result from habitat degradation and loss. Cumulative impacts are the combined outcome of numerous actions and stresses that alone may have relatively minor effects, but together lead to substantive habitat degradation or loss. Restoration of specific degraded habitats may cumulatively benefit dependent organisms.

The overall effect of human-induced, habitat impacts on living resources has been expanding areas of low dissolved oxygen, coupled with nutrient enrichment and suspended sediment. Species that can tolerate the low dissolved oxygen, algae growth, and excess sediment thrive in degraded areas. These species include smaller, less desirable organisms such as jellyfish (Breitburg 1992; Breitburg et al. 1994), and toxic algae (Paerl 1982; Tester and Fowler 1990). In areas where there is no oxygen, only a few bacteria species can survive. Degraded areas not only impair fishery resources, they also impair other human uses such as swimming and drinking water supply.

Impact sources are natural events or human activities that can have individual or multiple effects. Impact from pollution originates from both point (outfall pipes, ditches) and nonpoint sources (stormwater runoff), primarily affecting water quality (the biological, chemical, and physical suitability of water relative to standards that support desirable living communities). Natural events and human activities also affect the physical habitat through storms, floods, construction activities, land clearing, and fishing. These sources are discussed briefly below and in great detail in the following chapters.

Broad coast wide threats to fish habitat are identified below and discussed throughout the plan as they apply to each coastal fish habitat.

- Fishing gear impacts: Negative impacts of fishing gear on habitat have been the subject of numerous studies (Adkins et al. 1983; Van Dolah et al. 1991; Dorsey and Pederson 1992; Collie 1998; Auster and Langton 1999; ASMFC 2000). Effects include uprooting vegetation, breaking physical structures, and digging and suspending sediment. Oyster dredging, in particular, may have played a significant role in the eutrophication of Pamlico Sound (Jackson et al. 2001).
- Marina and dock siting, and boating: The cumulative effects of increasing boater access facilities and associated boating activities are a concern due to documented negative impacts from operation of individual boats (Lockwood 1990; Milliken and Lee 1990; Wisby and Lopazanski 1995; Stephan and Bigford 1997; Crawford et al. 1998; Fonseca et al. 1998; SAFMC 1998) and access facilities (Allen and Hardy 1980; Johnston 1981; Van Dolah et al. 1984; DWQ 1990; Wendt et al. 1990; DWQ 1991; Weis and Weis 1994; Wisby and Lopazanski 1995; McAllister et al. 1996; NMFS 1998; SAFMC 1998; Weis et al. 1998). Some effects include disturbance and removal of sediment, changes in currents, and degradation/loss of wetlands and SAV.
- Shoreline stabilization: The increasing modification of natural shorelines to prevent or reduce landward migration of the shoreline (a natural process) is a major concern documented in numerous studies (Mock 1966; Ellifrit et al. 1972; Garbisch et al. 1973; Gilmore and Trent 1974; Knutson 1977; Walton and Sensabaugh 1979; O'Rear 1983; Reilly and Bellis 1983; Pilkey and Wright 1989; Van Dolah et al. 1992; Byrne 1995; Hackney et al. 1996; Pilkey et al. 1998; SAFMC 1998; Titus 1998; Donaghue 1999; Jutte et al. 1999; Taylor 1999; Cahoon et al. 2000; DMF 2000; Peterson et al. 2000; Waters and Thomas 2001). These modifications often result in loss of wetlands and shallow water habitats, reduced fish diversity and abundance, and changes in runoff patterns.
- Nonpoint source (NPS) pollution: While great advances in the control and reduction of point source pollution have been made in the past 25 years (<http://www.epa.gov/OWOW/NPS/facts/point1>, 2002), NPS pollution has become the most widespread source of water quality degradation in North

Carolina's streams and estuaries (DWQ 2000 – 305(b) report). The impacts and contribution of nonpoint source pollutants have been well documented (Duda 1982; Duda and Klimek 1982; Humenik et al. 1983; DEHNR 1996b; Mallin et al. 1997; Scott 1997; SAFMC 1998; Paerl et al. 1999; DMF 2000; Mallin et al. 2000). Some impacts include reduced availability of dissolved oxygen, reduced water clarity, and excessive nutrients that trigger algal blooms.

- Habitat loss: The physical degradation and loss of habitat is the most widespread source of impairment in coastal North Carolina streams (DWQ 2000 – 305(b) report). Sources of physical degradation and loss include:
    - Dredging and draining of wetlands (Sutter 1999; Dahl 2000; DWQ 2000a);
    - Conversion of habitat to impervious surfaces (Mallin et al. 1998; Mallin et al. 2000; White et al. 2000; Natural Resources Conservation Service (NRCS), unpub. data); and
    - Installation of dams, culverts, bulkheads (Mock 1966; Ellifrit et al. 1972; Garbisch et al. 1973; Gilmore and Trent 1974; Knutson 1977; Walton and Sensabaugh 1979; O'Rear 1983; Reilly and Bellis 1983; Pilkey and Wright 1989; Van Dolah et al. 1992; Byrne 1995; Hackney et al. 1996; Pilkey et al. 1998; SAFMC 1998; Titus 1998; Donaghue 1999; Jutte et al. 1999; Taylor 1999; Cahoon et al. 2000; DMF 2000; Peterson et al. 2000; DCM, unpub. data), and jetties.
- Shellfish harvest area closures: The increasing closure to harvest of shellfishing waters has been correlated with increasing coastal development and stormwater runoff (Maiolo and Tschetter 1981; DWQ (DEM) 1994; Frankenberg 1995; Reilly and Kirby-Smith 1999; DWQ 2001 – White Oak Basinwide Water Quality Plan; and DMF 2001a, b). Although such closures have no direct impact on shellfish (only human harvest is affected), presence of indicator bacteria is strongly correlated with presence of other pollutants and nutrients (Mallin et al. 2000; 2001).

In spite of the great stresses on North Carolina's coastal ecosystem, it has proven to be quite resilient, and it is generally healthy (DWQ 2000a). However, the number of water bodies showing danger signs is growing as human activities further stress the coastal area (Maiolo and Tschetter 1981; DWQ 2000a). The trend toward a largely degraded coastal ecosystem must not only be stopped, but reversed.

SUMMARY OF INTRODUCTION

Development of an effective Coastal Habitat Protection Plan (CHPP) is critical for long-term enhancement of North Carolina's coastal fisheries. The habitat section of the North Carolina Fisheries Reform Act (FRA) of 1997 is similar in some ways to the 1996 federal Sustainable Fisheries Act, which requires federal fishery management plans to include provisions for the protection of Essential Fish Habitat. The FRA requires the North Carolina Department of Environment and Natural Resources (DENR) to prepare a Coastal Habitat Protection Plan for the long-term enhancement of fisheries associated with coastal habitats. The plan is to identify threats and provide recommendations for management actions to protect and restore habitats critical to North Carolina's coastal fishery resources. Once adopted by the Coastal Resources, Environmental Management, and Marine Fisheries commissions, the plan will help to ensure consistent actions among the commissions, as well as among their supporting DENR agencies.

The CHPP focuses on four goals for protection of coastal fisheries habitat: improve the effectiveness of existing rules and programs; enhance habitat and protect it from physical impacts; protect and enhance water quality; and identify, protect, and enhance "strategic" habitats. The CHPP is built around six basic habitats utilized by coastal fishery species: water column, shell bottom, submerged aquatic vegetation, wetlands, soft bottoms, and hard bottoms. Detailed information is provided on each habitat's description and distribution, ecological role and functions for finfish and shellfish resources, status and trends, threats, and management needs. Each of the three Commissions that adopt the CHPP will use it to develop coordinated coastal habitat protection strategies per the FRA requirements.

The CHPP area includes all waters flowing into North Carolina's coastal waters and the watersheds they drain, which are divided into 11 Management Units based on river basins. Plan development must take into account North Carolina's weather and climate, geology, and hydrology, as well as the effects of human population and land use. The current status of fisheries may be an indicator of the potential impacts of habitat degradation and loss, and the CHPP recommendations are intended to provide guidance that will support productive fisheries for future generations.

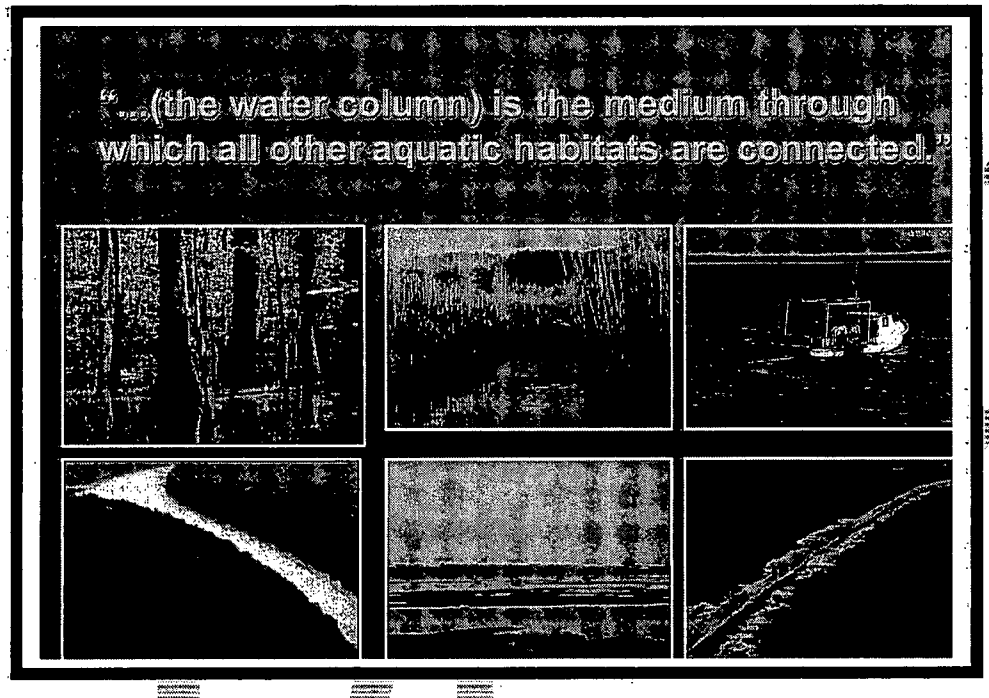
CHAPTER 2. WATER COLUMN

The quality of our coastal waters affects fish species diversity, production, and distribution but also living fish habitats, such as submerged aquatic vegetation and oyster beds (shell bottom). Water quality in the water column is a key factor that links fish, habitat, and people. That linkage is affected by growing development pressures along our coast as well as far inland, making the protection and enhancement of water quality for fisheries resources a challenging task. Determining the best course of action for enhancing water quality requires detailed knowledge of the water quality characteristics that various species require throughout their life cycle, along with the status, trends, and threats of those characteristics.



Water column habitat is defined in this plan as "the water covering a submerged surface and its physical, chemical, and biological characteristics." Differences in the chemical and physical properties of the water affect the biological components of the water column - including fish distribution. Water column properties that may affect fisheries resources include temperature, salinity, dissolved oxygen (DO), total suspended solids, nutrients (nitrogen, phosphorus), and chlorophyll *a* (SAFMC 1998). Other factors, such as depth, pH, water velocity and movement, and water clarity, also affect the distribution of aquatic organisms.

Coastal fisheries habitat may be found both in waters that are privately owned and in waters that are held by the state for the use of the public. Private waters include many lakes, ponds and some small streams. Public trust waters include all navigable waters and the lands beneath them, from the mean high water mark or mean water level, within state jurisdiction. The public has the right to use public trust waters for travel, recreation, and other activities (i.e., commercial and recreational fishing) that do not degrade acceptable public uses or biological and physical functions of those water bodies [CRC rule 15A NCAC 07H .0207(a)-(c)].

The Environmental Management Commission (EMC) classifies surface waters according to the best use

of the water (e.g., water supply, aquatic life protection, and swimming) and adopts water quality standards intended to protect the designated uses. Supplemental surface water quality classifications provide additional protection to waters that have special physical, chemical, biological, or use characteristics. These standard and supplemental classifications are depicted in Maps 2.1a-b and 2.2a-b, and are also described below.

Primary Surface Water Classifications:
C or **SC***—Supporting secondary recreation (including swimming on an unorganized or infrequent basis); wildlife; fishing; fish and other aquatic life propagation and survival; agriculture and any other usage, except for primary recreation or water supply.
B or **SB***—Supporting primary recreation (including swimming on an organized or frequent basis) and all uses specified for Class C or SC (and not water supply use).
WS—Water supply in natural and undeveloped watersheds (WS-I), predominantly undeveloped watershed (WS-II), low to moderately developed watersheds (WS-III), and moderately to highly developed watersheds (WS-IV), plus former or industrial potable water supplies or waters upstream and draining to WS-IV waters (WS-V).
SA*—Commercial shellfishing waters and all Class SC and SB uses.
* = saltwater classification

Supplemental Surface Water Classifications:
ORW (Outstanding Resource Waters)—Unique and special waters that are of exceptional state or national recreational or ecological significance which require special protection to maintain existing uses. These waters have been identified as having excellent water quality in conjunction with at least one important resource value.
HQW (High Quality Waters)—Waters rated as excellent by DWQ; Primary Nursery Areas or other functional nursery area; Native and Special Native Trout Waters and their tributaries; WS-I, WS-II and SA waters and waters for which DWQ has received reclassification to WS-I or WS-II.
NSW (Nutrient Sensitive Waters)—Waters needing additional nutrient management due to their being subject to excessive growth of microscopic or macroscopic vegetation.
SW (Swamp Waters)—Waters with low velocities and other characteristics different from adjacent waterbodies (generally low pH, DO, high organic content).
FWS (Future Water Supply)—Water designated for future water supply use.
TR (Trout Waters)—Waters protected for natural trout propagation and stocked trout survival.

The Marine Fisheries Commission (MFC) designates areas subject to commercial and recreational fishing regulations (Map 1.3). The MFC and the Wildlife Resource Commission (WRC) also designate areas with ecological functions vital to fish and shellfish production, such as nursery and spawning areas for finfish and crustaceans (Maps 2.3 and 2.4).

Nursery areas: Those areas in which for reasons such as food, cover, bottom type, salinity, temperature and other factors, young finfish and crustaceans spend the major portion of their initial growing season [MFC rule 15A NCAC 03N .0102 (a)].
Primary nursery area: Those areas of the estuarine system where initial post-larval development takes place. These areas are located in the uppermost sections of a system where populations are uniformly very early juveniles [MFC rule 15A NCAC 03N .0102 (b)].
Secondary nursery areas: Those areas of the estuarine system where later juvenile development takes place. Populations are usually composed of developing sub-adults of similar size which have migrated from upstream primary nursery areas to the secondary nursery area located in the middle portion of the estuarine system [MFC rule 15A NCAC 03N .0102 (c)].
[Inland] primary nursery areas: Those [inland] areas inhabited by the embryonic, larval, or juvenile life stages of marine or estuarine fish or crustacean species due to favorable physical, chemical or biological factors [WRC rule 15A NCAC 10C.0502].
Anadromous fish spawning areas: Those areas where evidence of spawning of anadromous fish has been documented by direct observation of spawning, capture of running ripe females, or capture of eggs or early larvae [MFC rule 15A NCAC 031 .0101 (b) (20) (C)].
Anadromous fish nursery areas: Those areas in the riverine and estuarine systems utilized by post-larvae and later juvenile anadromous fish [MFC rule 15A NCAC 031 .0101 (b) (20) (D)].

The MFC and WRC habitat designations generally include a complex of habitats, of which the water column is one component. These definitions and classifications of water column habitat and their associated regulatory jurisdictions provide the authority for management actions.

2.1. DESCRIPTION AND DISTRIBUTION

The water column is the dominant component and bonding element of the entire coastal aquatic ecosystem, integrating aquatic influences from both land and sea (15A NCAC 07H .0206 (b)). The coastal aquatic ecosystem is divided among several river basins draining into North Carolina's coastal area. Within a river basin, characteristics of the water column change markedly from the basin's extreme headwaters to the ocean. The primary variable that changes is salinity. Based on salinity variation, there are three major systems in coastal North Carolina: 1) fresh water, 2) estuarine, and 3) marine. To a large extent, differences in salinity determine the species found in coastal waters (Ross and Epperly 1985; Noble and Monroe 1991). Within each system, additional variation occurs as a result of water velocity, substrate, sediment transport, and depth.

Freshwater systems

Freshwater systems are generally considered to have salinity between 0 and 0.5 ppt (Cowardin et al. 1979, SAFMC 1998; Map 2.5a-b). Freshwater water bodies include rivers, creeks, lakes, and ponds.

Rivers and creeks

The characteristics of river and creek water depend on climate, geology, topography, and land cover. The coastal plain is relatively flat, with a basin slope of approximately one foot per mile (DWQ 1997a), higher in the southern portion and lower in the northern portion. Streams in the coastal plain are often slow flowing, with extensive swamps, bottomland hardwood forest, and marshes in their floodplains (DWQ 1997a). These streams are often acidic from high inputs of dissolved organic matter, a condition known as "dystrophy" (Wetzel 2001). These "blackwater" systems often have moderate phytoplankton production, but, given a source of human-generated nutrients and an open canopy, shallow blackwater streams can support dense phytoplankton blooms (Ensign and Mallin 2001; Mallin et al. 2001a). Dissolved oxygen and pH are also influenced by dystrophy. Where slow-moving water bodies drain wetlands with decaying vegetation, the water column has high concentrations of dissolved organic carbon (humic acids), low pH, and low dissolved oxygen (DO). Water column characteristics change as one moves from the river's headwater tributaries to its mainstem channel. Changes include a shift to increasing turbidity, depth (Sheehan and Rasmussen 1993), phytoplankton abundance, and flooding frequency. There also tends to be a decrease in particle size of organic matter (Vannote et al. 1980), an increase in the importance of floodplain wetlands (Junk et al. 1989), and more continuous flow in downstream areas.

Rivers and creeks also exhibit seasonal variations in stream flow, suspended particle concentrations, and water temperature. Average monthly discharge among all coastal river basins peaks in March, declines throughout the summer and fall, and gradually increases again around November (Figure 2.1). This discharge pattern also corresponds with low and high-salinity time periods in downstream estuaries. Flow variability also follows the general discharge pattern, with the highest variability during March. Heavy spring flows carry relatively high sediment loads, which, in combination with spring algal blooms, result in increased turbidity. Water temperatures are generally highest from June to September (25-27° C) and lowest during December - January (5-9° C) (Figure 2.1). From 1969 to 1999, annual discharge patterns within river basins appear to rise and fall on a 2-5 year cycle (Figure 2.2; see Map 2.6 for USGS stream gauge stations used).

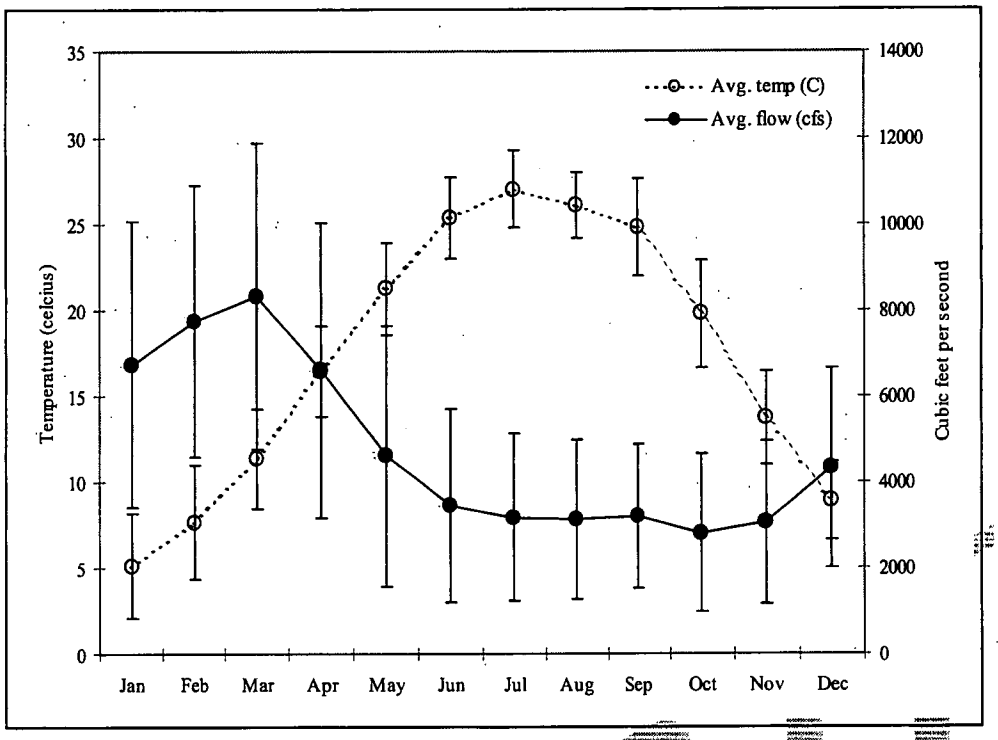


Figure 2.1. Average and standard deviation of monthly discharge (time period: 1969-1999, n = 1,464) and water temperature (time period: 1953-2001, data points per month = 52-123). *[Source: USGS hydrologic monitoring stations on the lower Roanoke, Tar, Neuse, and Cape Fear rivers, North Carolina. (Station locations are marked on Map 2.6.)]*

Five major riverine systems flow into North Carolina's coastal waters: Chowan, Roanoke, Tar-Pamlico, Neuse, and Cape Fear (Map 1.1). Smaller, coastal plain systems include the New and White Oak river basins, the blackwater rivers of the Pasquotank basin (Albemarle MU), and the coastal streams of the Lumber River basin (Southern Estuaries MU). Of the smaller systems, only the blackwater rivers of the Pasquotank basin (Albemarle MU) have a significant freshwater component. The New, White Oak, and coastal streams of the Lumber river (Southern Estuaries MU) basin are primarily estuarine.

The Chowan, Tar-Pamlico, Neuse, and Cape Fear Rivers are contained entirely within the coastal plain and piedmont regions, while the Roanoke River flows from the mountains to the coastal plain region. With the exception of the Albemarle, Chowan and Roanoke basins, which originate in Virginia, all are located entirely within North Carolina. The Cape Fear River is the only major river system that flows directly into the ocean. The other riverine systems all discharge into coastal estuaries behind barrier islands.

The WRC has designated most of the main stem of the Roanoke, Tar, Neuse, and Cape Fear rivers within its jurisdiction as Inland Primary Nursery Areas (Map 2.4). The WRC has also designated certain inland waters near the coast as PNAs based on recommendations by DMF. While there are few MFC designated nursery areas within inland fishing waters, DMF sampling data show many of freshwater tributaries function as anadromous fish spawning and nursery areas.

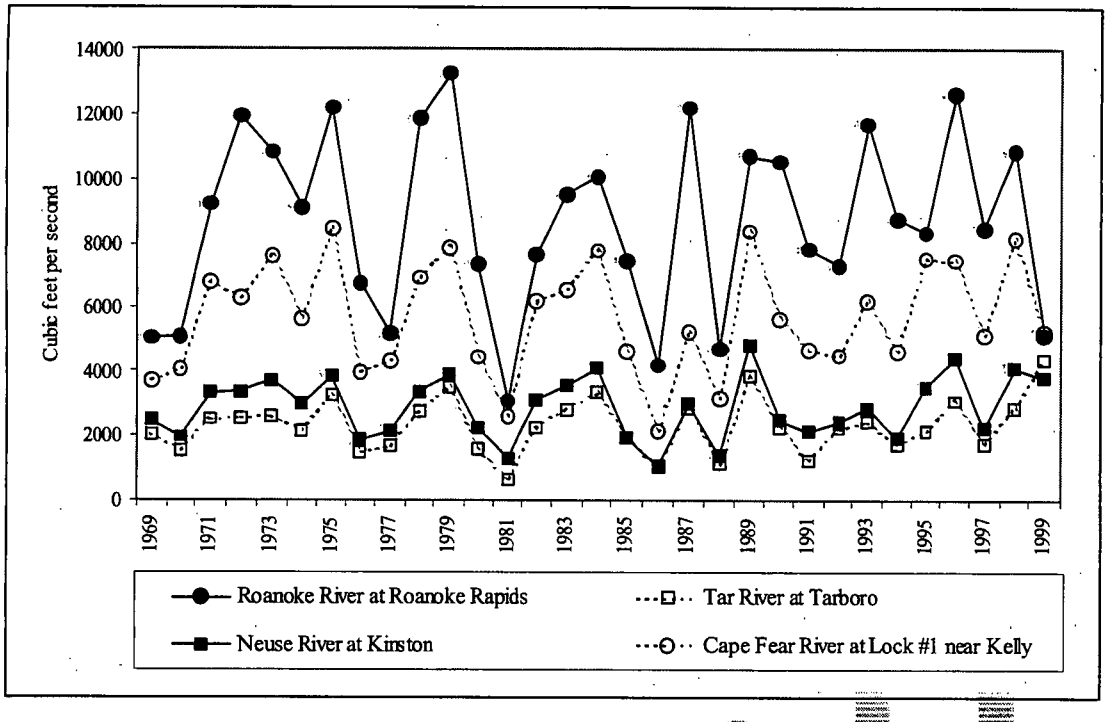

Figure 2.2. Average annual discharge in the Roanoke, Tar, Neuse, and Cape Fear rivers during 1969-2001 based on data from the USGS hydrologic monitoring stations. *(Station locations are marked on Map 2.6)*

Lakes and impoundments

The water column in lakes and ponds can be vertically stratified in temperature, DO, and related physical and chemical parameters. However, during strong winds or seasonal turnover (spring/fall), the water column's layers may become mixed so that there is less variability based on depth. Overall, water column characteristics in lakes depend on the lake's origin, underlying geology, and land cover in the watershed. Many natural lakes in North Carolina were formed by the solution of minerals in ground water (Menhinick 1991). They are shallow (maximum depth about 2 m) and generally circular (Crowell 1966). The Carolina Bays are an example of these systems. Most of these natural lakes, similar to coastal blackwater rivers and creeks, have low pH and are naturally dark in color from organic staining.

There are 16 natural lakes in North Carolina's coastal plain (Menhinick 1991). There are many other small natural ponds and impoundments. However, there are only a few lakes whose connection with coastal waters is unobstructed by a dam or other impassable feature. The lakes that directly connect to coastal waters include Alligator Lake, Great Lake, Ellis Lake, and Pungo Lake (Map 1.1). Lake Phelps has a sporadic connection to coastal water via several man-made canals. Except for Lake Phelps, which is designated as a State Park, these natural lakes are largely under federal government jurisdiction in Croatan National Forest and national wildlife refuges. The feeder creeks and canals flowing into them are partially under state and private ownership.

The natural coastal lakes range in size from 2,789 (Great Lake) to 41,084 acres (Lake Mattamuskeet). Lake Mattamuskeet, the largest natural lake in North Carolina, connects to coastal waters through several man-made drainage canals - a connection demonstrated by the frequent occurrence of adult blue crabs in the lake (Rulifson and Wall 1998). The canals draining Lake Mattamuskeet have historically supported significant anadromous alewife spawning runs that have shown signs of resurgence in recent years (Epperly 1985; Winslow et al. 1983b; R. Rulifson, ECU, pers. com., 2002). There are research and

management activities currently underway to maintain and enhance the connections between Lake Mattamuskeet and other lakes on the Albemarle-Pamlico peninsula and coastal waters to benefit coastal fishery species utilizing these waters (R. Rulifson, ECU, pers. com., 2002).

Estuarine systems

Water column characteristics in estuaries are a dynamic mix of adjacent riverine and marine systems. Estuaries occupy the transition between freshwater and marine systems, where circulation patterns are determined by prevailing winds, buoyancy-driven flows, and lunar tides. Estuarine-dependent species comprise more than 90% of North Carolina's commercial fisheries landings and over 60% of the recreational harvest (by weight) (from DMF annual commercial and recreational fisheries landings data). This Plan uses three salinity zones[1] for simplicity and consistency with established definitions (Bulger et al. 1993):

- low-salinity (0.5-5 ppt) (also known as oligohaline)
- moderate-salinity (5-18 ppt) (also known as mesohaline)
- high-salinity (18-30 ppt) (also known as polyhaline)

Boundaries between salinity zones change in response to water flow, weather conditions, and tidal fluctuations. Flooding can result in fresh water expanding seaward over denser masses of water in the "mixing zone" (0.5-25 ppt). Conversely, dry weather can result in seawater advancing into typically freshwater areas. Less drastic are tidal changes resulting in periodic additions of seawater to the mixing zone. The mixing zone receives coarser-grained sediments, saline water, and migrating organisms from the flood tide, while the ebb tide brings finer-grained sediment, fresh water, nutrients, and organic matter (SAFMC 1998). This dynamic system is mediated by a series of inlets along a chain of barrier islands separating the ocean from the adjacent estuary. Salinity in estuaries also varies in accordance with the seasonal pattern of river input depicted in Figure 2.1. Salinity within estuaries is generally lowest from December to early spring and highest from late spring to early fall (Orlando et al. 1994). Similarly, water temperatures are lowest during mid-winter and highest during the summer.

Pilkey et al.'s (1998) analysis of North Carolina's shore and barrier islands revealed much about the variation in salinity and tidal amplitude along North Carolina's coast due to the slope of the coast. Steeper slopes with relatively short basin profiles result in less river input and greater tidal amplitude from increasing oceanic influence. In these areas, numerous inlets develop along short barrier islands protecting narrow, back barrier sounds. Small rivers draining these areas form trunk estuaries (drowned river estuaries perpendicular to the coast) where low volumes of organic-stained fresh water mix with seawater. As a result, small trunk estuaries exhibit a distinct salinity gradient from upstream fresh waters to the ocean, while narrow back barrier sounds maintain high salinities from regular lunar tides. Other areas have gentler slopes and relatively long basin profiles, with more river input and lower tidal amplitude from reduced seawater intrusion; such areas have few inlets and long barrier islands protecting extensive back barrier sounds with highly variable salinity. Large rivers flowing into the sounds form trunk estuaries with very low salinity.

Strong winds are a major component of water movement in large, irregularly flooded estuarine systems. At locations relatively isolated from inlets in the Albemarle-Pamlico Sound system, the effects of lunar tides are small (a few inches at most) whereas those of wind tides can be much greater (especially during storms). A strong wind tide often floods the windward shore, exposing bottom along the leeward shore. This situation can also result in colder, nutrient-rich water welling up along the leeward shore. Wind tides also affect salinity in the estuary, by pushing high-salinity water from the ocean toward the estuary.

[1] A five-zone scheme was used on existing salinity maps from NOAA: 1) 0-0.5 ppt (fresh water), 2) 0.5-5 ppt (low-salinity), 3) 5-15 ppt (moderate-salinity), 4) 15-25 ppt (high-salinity), and 5) >25 ppt (highest salinity) (Map 2.6). The low-salinity zone used in this document covers NOAA's zone (2) and the moderate-salinity zone covers NOAA's zone (3). The high-salinity zone is a combination of NOAA's high (4) and highest (5) salinity zones (15 to >25 ppt).

For example, one model of the Albemarle-Pamlico system indicates that southwesterly winds cause the formation of low-salinity plumes from Oregon Inlet seaward while wedge-shaped high-salinity plumes enter Pamlico Sound from Hatteras and Ocracoke Inlets (Xie and Pietrafesa 1989). This hydrodynamic model predicted the opposite effect during cold fronts, when northwesterly winds caused a wedge-shaped, high-salinity plume on the sound side of Oregon Inlet.

Circulation, by wind or lunar tide, can increase DO levels in bottom water. But while lunar-driven systems receive regular circulation, wind-driven systems depend on variable weather conditions (Leuttich et al. 1999; Borsuk et al. 2001). Irregular mixing can result in stratification of the water column and hypoxia or anoxia during periods of warm, calm weather. Anoxia can also develop with light winds if a strong vertical salinity gradient is present, especially during westerly winds.

Large back barrier sounds and trunk estuaries

Large back barrier sounds occur north of Cape Lookout and include Albemarle, Currituck, Croatan, Roanoke, and Pamlico sounds (Map 1.1). Large trunk estuaries flowing into these northern sounds include the Alligator, Pungo, Pamlico, and lower Neuse rivers. The Albemarle-Pamlico sound system (not including Core Sound) connects with nearshore ocean waters through Oregon Inlet in the north, and Hatteras and Ocracoke inlets in the south. These large sounds are of prime importance for North Carolina's fishery productivity. Small tributary estuaries in west and northwest Pamlico Sound provide important fish nursery habitat. Outstanding Resource Waters within these northern estuaries include the Alligator River and an area extending offshore from Swan Quarter National Wildlife Refuge. The Alligator River is also classified as Swamp Water. Nutrient Sensitive Waters include the Pamlico, Neuse and Pungo rivers as well as southwest Pamlico Sound (Map 2.2a-b).

The Albemarle-Pamlico system has a long flushing period (about 272 days) relative to the other North Carolina estuarine systems. Since the large trunk estuaries flowing into Pamlico Sound flush more rapidly than Pamlico Sound, the sound acts as a settling basin for sediments and nutrients (Giese et al. 1979). Near inlets in the Albemarle-Pamlico system, lunar tides are the dominant influence on salinity variation and water column mixing (Orlando et al. 1994). Elsewhere, wind mixing is the dominant factor. Management of river flows can also affect salinity. Releases from Roanoke Rapids Lake and other Roanoke River reservoirs during low-flow periods are generally effective in keeping higher salinity waters out of Albemarle Sound (Giese et al. 1979), except during extreme droughts. Seasonal variation in fresh water has a major effect on salinity (Map 2.5a-b). Different salinity layers can occur in estuaries lacking a direct connection to the ocean, such as the Cape Fear and Northeast Cape Fear rivers (Orlando et al. 1994). Different salinity layers can also occur in Albemarle Sound during period of calm or high freshwater inflow (Steel 1991). Although the major factors driving large-scale salinity change are fairly simple in estuaries, the factors underlying smaller-scale horizontal and vertical variation can be very complex, both spatially and temporally.

Small back barrier sounds and trunk estuaries

South of Cape Lookout, back barrier sounds and trunk estuaries begin to narrow as the basin slope becomes steeper. Starting at Core Sound in the north, small back barrier sounds continue south with Bogue Sound and some very narrow sounds located between the small trunk estuaries of the New and White Oak estuaries and the more riverine lower Cape Fear River. Some of these smaller sounds are Stump Sound, Topsail Sound, Masonboro Sound, and Myrtle Grove Sound (Map 1.1). Other small trunk estuaries include the Newport and North rivers along Bogue and Back sound. These small back barrier and trunk estuaries contain numerous designated nursery areas and Outstanding Resource Waters (Map 2.3a-b). The only Nutrient Sensitive Water among small back barrier sounds and trunk estuaries is the upper New River (DWQ, unpub. data).

In Bogue and Back sounds, lunar tides are the dominant influence on salinity and water column mixing

(Orlando et al. 1994) and flushing rates are faster than in the larger sounds. Winds and freshwater inflow are secondary influences on salinity variation, but may cause major seasonal differences in salinity.

During late winter (January-March) and summer (June-August), surface and bottom salinities are only weakly stratified in Bogue Sound. Large seasonal differences in surface salinity occur. The very small back barrier sounds found in the Southern Estuaries MU have high salinities year-long. In upper sections of the New River, freshwater inflow is the dominant influence on salinity (Orlando et al. 1994). In the lower New River estuary, lunar tides have the greatest influence on salinity variation. Spatial and temporal salinity variation in the New and White Oak rivers can be seen in Map 2.5a-b.

Cape Fear River estuary

The Cape Fear River is the only major river in North Carolina flowing directly into the ocean, making the Cape Fear River estuary unique among North Carolina estuaries. The lower river is essentially a large trunk estuary, but with a much steeper gradient in salinity than large trunk estuaries in the northern part of the coast. The upper Cape Fear estuary is composed almost entirely of low-moderate salinity fish nursery areas (Map 2.5a-b).

In the upper Cape Fear River estuary (north of Wilmington), seasonal patterns of freshwater inflow have the greatest influence on salinity (Orlando et al. 1994). Discharge from the principal rivers in the Cape Fear basin is three times greater during the high-flow period than during the low-flow period. Short-term increases in freshwater discharge also influence salinity in the upper estuary, displacing bottom water downstream and homogenizing the water column (Giese et al. 1979). In the lower and middle estuary, lunar tides have the dominant effect on salinity variation. Due to the relatively high discharge and low volume of the Cape Fear estuary, the flushing rate is approximately 14 days (Table 2.1), the most rapid turnover among major estuaries in North Carolina. Map 2.5a-b depicts the seasonal salinity in the Cape Fear River system.

Table 2.1. Hydrologic and hydrodynamic characteristics of major estuaries in North Carolina. *(Source: Basta et al. 1990)*

Estuary	Drainage area (mi^2)	Surface area (mi^2)	Avg. depth (ft)	Volume (billion ft^3)	Avg. daily freshwater input (100 cfs)	Flushing period (days)
Albemarle-Pamlico sounds*	29,600	2,949	13	1,081	460	272
Pamlico-Pungo River	4,300	166	9	44	46	111
Neuse River	5,600	173	12	55	62	103
Bogue-Core sounds and White Oak River	700	102	5	13	13	116
New River	500	32	6	5	8	72
Cape Fear River	9,100	38	11	12	101	14

* Includes Core Sound NOTE: flushing period = volume / average daily freshwater input

Marine systems

Marine systems are defined as open ocean waters overlying the continental shelf and its associated high-energy coastline where salinities exceed 30 ppt (Cowardin et al. 1979). This Plan addresses the ocean waters within the State's territorial jurisdiction, which extends three nautical miles offshore.

The effects of tides and bottom friction are most evident near inlets and along the shoreline. Tidal amplitude along North Carolina's ocean shoreline is greatest in the southern coastal area where the

continental shelf is widest. The average tidal height in North Carolina is approximately 2 ft (0.6 m) near Cape Hatteras and 4.3 ft (1.3 m) near Cape Fear. A considerable amount of mixing is provided by the turbulence of twice-daily tides.

The effects of freshwater runoff are also most apparent near inlets and river mouths. Salinities are lowest in coastal marine systems during periods of maximum freshwater runoff in April. The Cape Fear River is a major source of direct river runoff into southern North Carolina's ocean waters. Low-salinity waters also enter the ocean through the multiple inlets along the coast and from southerly flow of Chesapeake Bay waters along the Outer Banks. The plume of lower-salinity Chesapeake Bay water is pushed southward by the southerly-flowing coastal frontal zone (CFZ).

Winds are important in all layers of the marine water column. Wind stress can alter or reverse the generally southern pattern of flow in the CFZ (Blanton et al. 1999). Winds can also mix and move water masses inshore. In the mid-Atlantic, waters from Gulf Stream intrusions move across the shelf at a rate of approximately 2-3 mi/day (3-5 km/day), and parallel to the coast at a rate of approximately 3-9 mi/day (5-15 km/day) (Hare et al. 1999). Georgian shelf waters flow into the Carolina Capes region during periods of persistent southwesterly winds, while Virginian coastal waters flow south across Diamond, and occasionally Lookout, shoals during periods of persistent northerly winds (Pietrafesa 1989). Current and wind patterns will have a strong effect on the recruitment and retention of various fish larvae from different offshore areas.

Major oceanic currents off North Carolina are the Gulf Stream and Virginia Coastal Labrador current. The warm, north-flowing Gulf Stream and cool, south-flowing Virginia Coastal Labrador current meet near Cape Hatteras, separating mid- and south Atlantic waters. The position of these major water masses is clearly seen in sea surface temperature data from satellite imagery (Map 2-7). Warm Gulf Stream waters tend to elevate temperatures and salinities in the water column south of Cape Hatteras (Menzel 1993). The cool, lower salinity Virginia Current runs along the northern shore of the Outer Banks, and tends to lower temperature and salinity of the water column (Pietrafesa 1989). Temperatures on the inner shelf are uniform throughout the water column in the fall and winter. During summer, inner shelf waters are often stratified (Menzel 1993). Gulf Stream waters are the transport mechanism for many larval fish species, nutrients, and phytoplankton into North Carolina's shelf waters (Govini and Spach 1999). The red tide episode that occurred in North Carolina coastal waters in 1987 was attributed to a Gulf Stream water intrusion, carrying the toxic dinoflagellate *Ptychodiscus brevis* (Tyler 1989).

Shoals extending roughly perpendicular from shore accompany capes and inlets along North Carolina's coastal ocean. Oceanic currents interacting with these shoals create upwellings of nutrient-rich bottom water. There is also a strong upwelling along the beaches north of Oregon Inlet during the summer caused by southwest winds, resulting in surface water temperature changes of 10° F (5.5°C) in one or two days. In offshore areas, the interaction of frontal zones and bottom topography can often result in nutrient-rich upwellings. Upwellings also recycle nutrients locked under a strong halocline. The most probable locations of upwellings and their associated blooms are around Cape Hatteras. Upwellings, associated currents, and winds can also transport phytoplankton and floating *Sargassum* weed (from the Sargasso Sea) into nearshore coastal waters.

Habitat requirements for aquatic life

Unlike other fish habitats, the water column will persist regardless of environmental conditions. However, the quality of the water column may not be suitable to support certain fish species or ecological functions. Fish and invertebrate species occur where physical and chemical characteristics (i.e., temperature, DO, salinity, clarity) suit their physiological requirements. The following paragraphs discuss the differentiation of fish community structure along important physical and chemical gradients in coastal North Carolina.

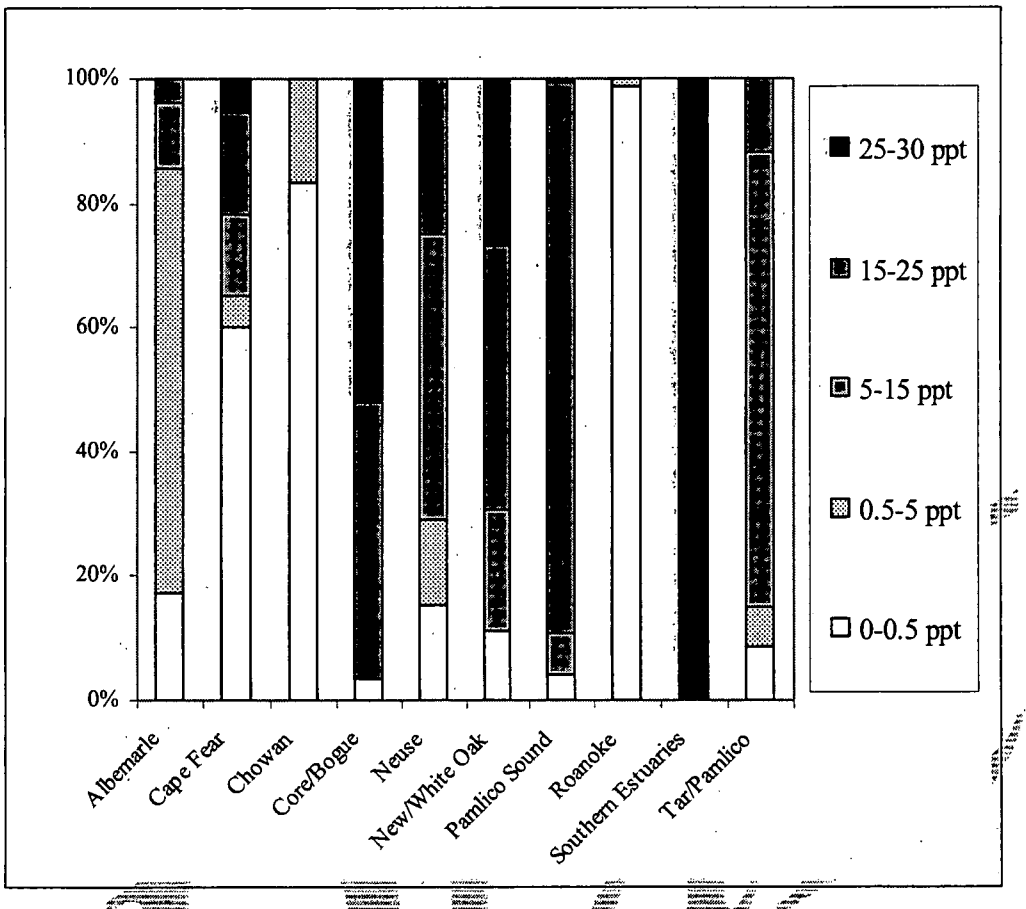

Figure 2.3. The relative proportion of average salinity zones within CHPP management units (excluding the coastal ocean). *[Source: NOAA's 1:100,000 scale salinity mapping (Coastal Ocean Resource Assessment Program). The area for 0-0.5 ppt includes only mainstem rivers and lakes in the management unit.]*

Salinity

The proportion of the different salinity-based systems within each CHPP management unit varies (Table 2.2). The Albemarle, Chowan, and Roanoke MUs are primarily freshwater and low-salinity systems, whereas Core/Bogue, Coastal Ocean and Southern Estuaries MUs are primarily high-salinity estuarine or marine systems (Figure 2.3). The salinity characteristics of any given estuary are a major determinant of aquatic community composition.

Salinity is among the key factors shaping fish communities in North Carolina estuaries (Ross and Epperly 1985; Noble and Monroe 1991). Some aquatic species are capable of tolerating large variations in salinity (blue crab), while others are capable of living in only a narrow salinity range (i.e., black sea bass). Salinity has a major role in the distribution of aquatic species (Szedlmayer and Able 1996). A partial list of important fish species in North Carolina coastal waters is shown in Table 2.3. Species are organized by salinity zones of spawning and nursery areas to give an indication of where species occur in coastal waters.

In low-salinity areas of the Albemarle-Pamlico system, the fish community is dominated by freshwater and anadromous species (Table 2.3). In late winter, river herring (blueback herring and alewife), striped

bass, Atlantic sturgeon, and other anadromous species migrate from the ocean and lower estuary to spawn upstream in freshwater areas. After spawning, the adults migrate back to the lower estuary or oceans, while the juveniles spawned in spring begin their seaward migration in late fall. This pattern holds for all the rivers in eastern North Carolina (Sholar 1975; Marshall 1976; Sholar 1977; Fischer et al. 1979; Hawkins 1980). The Albemarle-Pamlico system also has a resident population of striped bass that contribute little to the ocean migratory stock (Hassler et al. 1981; DMF 2003b).

Southern Estuaries	0	0	0	5	15,248	15,253
Tar/Pamlico	10,694	7,832	89,950	14,616	0	112,397
TOTAL	**418,673**	**490,593**	**310,840**	**1,113,455**	**124,305**	**2,039,194**

In the Albemarle-Pamlico system, striped bass and American shad primarily use the Roanoke, Tar, and Neuse rivers (Steel 1991). River herring spawn in these rivers as well as most of the smaller tributaries of the Albemarle Sound system and the canals connecting Lake Mattamuskeet with coastal waters. River herring are also present in riverine waters south of the Albemarle-Pamlico system, where they have been studied in the New and White Oak rivers (Sholar 1975) and Cape Fear River (Sholar 1977; Fischer 1979; Rulifson et al. 1982).

During spring and summer, juvenile and adult estuarine species spawned in high-salinity estuarine waters (i.e., blue crab, red drum, weakfish) or the nearshore ocean (i.e., Atlantic menhaden, Atlantic croaker, spot, southern flounder) occupy the low-salinity zone (Table 2.3). There are also some resident species that complete their entire life cycle in the low-salinity zone. Residents include estuarine species like bay anchovy but are dominated by freshwater species, such as white perch, yellow perch, catfishes, sunfishes, and minnows (Keefe and Harriss 1981; Copeland et al. 1983; Epperly 1984). Prominent species in this resident group include the spring-spawning white perch and white catfish (Keefe and Harriss 1981). Both species use the entire Chowan River and other areas as nursery habitat, but generally occupy deeper areas during winter (Hester and Copeland 1975). The low-salinity zone is also occupied by the catadromous American eel.

In moderate- and high-salinity estuarine zones, the young of offshore winter and spring spawners, such as Atlantic menhaden, spot, and Atlantic croaker, predominate (Table 2.3; refer to Nursery function section). Common, year-round residents of the nearshore marine zone include bottom fish such as black sea bass, gag, kingfishes, dogfish sharks, and summer flounder, along with more pelagic species like Spanish mackerel, king mackerel, cobia, silversides, and bluefish. Juveniles and adults of these species are also common in the high-salinity estuarine zone (NOAA 2001). Many high-salinity estuarine species are also found in the nearshore ocean (i.e., red drum, spotted seatrout, weakfish, black drum). During late fall and winter, the nearshore marine zone is flooded with adult offshore spawning estuarine species like southern

Table 2.3. Spawning location/strategy ("spawning guild") and vertical orientation of some prominent coastal fish and invertebrate species.

SPAWNING GUILD		Vertical orientation[1]	
Common name	Scientific name	Demersal	Pelagic
ANADROMOUS FISH			
Alewife	***Alosa pseudoharengus***	**E**	**A, J, L**
American shad	***Alosa sapidissima***	**E**	**A, J, L**

flounder, Atlantic croaker, spot, shrimp, striped mullet, and Atlantic menhaden. Florida pompano and Gulf kingfish are common species in the nearshore marine zone (primarily during the summer).

Temperature

Temperature patterns in North Carolina coastal waters affect fish distribution and functions. The North Carolina coast is located at the southern end of the cooler Mid-Atlantic Bight and the northern end of the warmer South Atlantic Bight, with Cape Hatteras marking the transition between these two major zones. As a result, some northern species are abundant in coastal ocean and estuarine waters north of Cape Hatteras, and some southern species are abundant south of Cape Hatteras. Predominantly northern fish include summer flounder, weakfish, spiny dogfish, and migratory striped bass, whereas primarily southern species include snappers, groupers, southern shrimps, and southern flounder.

In riverine systems, water temperature increases downstream from river headwaters to the estuary. The gradual increase in temperature is determined naturally by elevation, shading, and water velocity. Temperature in riverine systems is one of the primary cues for anadromous fish spawning. For example, spawning of striped bass in coastal rivers is triggered by increasing water temperatures in early spring (Funderburk et al. 1991).

The greatest variation in temperature within North Carolina's estuaries occurs from season to season and is highly influenced by high spring flows in the rivers feeding the estuary (Figure 2.1). Apart from very high river flows, the temperature of upper estuarine waters is most affected by air temperatures. For example, average monthly temperatures in the Pamlico River estuary range from 41°F (5°C) in January to 81°F (27°C) in July and August, but in extreme conditions may range from 32° to 86°F (0-30°C) (Copeland et al. 1984). The seasonal temperature range of the Pamlico River estuary follows the average monthly temperature of upstream rivers very closely (Figure 2.1). Estuarine water temperature also responds to the tides (Peterson and Peterson 1979). In winter, water temperatures near ocean inlets rise abruptly with the incoming tide, whereas, during summer, the incoming tide is cooler (Peterson and Peterson 1979). Estuarine, and especially slow-moving or stationary, organisms have adapted to survive these short-term and seasonal conditions.

In general, all estuarine organisms can tolerate a very wide range of temperatures, if given adequate time to acclimate (Nybakken 1993). Organisms cannot readily adapt to a rapid increase or decrease in temperature. Early life stages of many species (i.e., clams, oysters, spot, croaker, flounder, menhaden) have a much narrower temperature tolerance than adults (Kennedy et al. 1974). If water temperature becomes too low, or falls too rapidly, there can be a fish kill of sensitive species like seatrout and red drum. Great variability in annual reported catch is typical for seatrout species and seems related to climatic conditions of the preceding winter and spring. Low catches follow severe winters; winter cold shock of juveniles and adults is cited as a primary factor in local and coastwide declines in spotted seatrout (<http://www.ncdmf.net/stocks/spectrou.htm>, July 2003).

Temperature varies least in the marine system (Peterson and Peterson 1979; Nybakken 1993) and marine species tend to be less tolerant of temperature extremes and rapid changes in temperature. Water temperature is one of the most important factors in determining use of coastal ocean habitat by warm temperate and tropical species (SAFMC 1998). Tropical species occur off the North Carolina coast where offshore bottom water temperatures range from approximately 52-81°F (11–27°C) (SAFMC 1998). Temperatures less than 54°F (12°C) may result in the death of some tropical fish and invertebrates (SAFMC 1998; Wenner et al. 1984). Estuarine-dependent species in the nearshore ocean, such as black sea bass and southern flounder, have a broader temperature tolerance (Steimle et al. 1999; Reagan and Wingo 1985). Research in North Carolina marine waters has found that fish species composition at hard bottom shifted over a 15 year period, with an increase in tropical species and decrease in temperate

and other parameters in order to evaluate the relative contribution of water clarity in determining fish community structure.

Flow and water movement

Estuaries are mixing zones with complex water movements between fresh and salt water. The four principal factors that affect water movement in North Carolina's estuaries are: (1) rainfall (inflow), (2) wind, (3) lunar tides, and (4) density gradients (salinity and temperature) (DMF 2003b). Each creek, river, bay, or sound is uniquely different due to these four factors.

Flow and circulation patterns within North Carolina's estuaries are complex due to interacting physical, chemical, and biological factors. Variation in water flow occurs at a broad range of spatial scales in estuarine and marine systems. The interaction of topographic features (e.g., shoals, bays) and tidal or wind-driven circulation patterns creates large-scale (km) spatial variation (Xie and Eggleston 1999; Inoue and Wiseman 2000). At much smaller scales (<1m), topographic changes or the presence of bottom habitat structure (e.g., SAV, oyster reef, pilings, stumps, logs) can create areas of reduced and increased water velocity (Jokiel 1978; Gambi et al. 1990; Komatsu and Murakami 1994; Lenihan 1998). Temporal variation in flow is caused by regular tidal flushing or irregular circulation by the wind.

Each organism in an estuary relies upon certain circulation patterns to provide the conditions that it needs to flourish at a given life stage. Some conditions benefit one species or species life stage more than others. The conditions needed by a species do not always occur at the same time and location each year due to variations in weather. However, the expansive nature of North Carolina's estuaries almost assures that proper conditions for a particular species will occur somewhere, but conditions may not be optimal in all locations (DMF 2003b).

The aquatic organisms that flourish in estuaries rely on flow and water movement to: (1) deliver the nutrients and physical water conditions for appropriate food and nursery area development at the opportune time; (2) keep eggs and larvae of pelagic spawners in suspension to enhance survival; (3) transport and distribute eggs, larvae, and juveniles to the appropriate nursery area for optimum food availability and protection from predators; and (4) distribute sediment and affect structures that serve as habitats (i.e., shell bottom, SAV, soft bottom) for many fish species (DMF 2003b).

High flows serve as a cue for spawning activity of anadromous fish, whereas low flows correspond to the growth and recruitment period of young fish (Orth and White 1993). Successful spawning of striped bass coincides with optimal water velocities between 3.3 and 6.6 ft/s (100-200 cm/s), while adult American shad prefer water velocities between 2 and 3 ft/s (61-91 cm/s) (Fay et al. 1983a; Mackenzie et al. 1985). For example, recruitment of larval river herring in tributaries of the Chowan system is related to flow conditions (O'Rear 1983). However, water velocity is not the only cue for anadromous fish spawning; increasing light and temperature are also important factors.

Flows have a major effect on biological interactions. Powers and Kittinger (2002) found that blue crab predation on juvenile hard clams and bay scallops decreased with increasing water velocity, while whelk predation on bay scallops increased under the same treatment. Dilution of water-borne chemical cues was likely the reason for reduced blue crab predation (Powers and Kittinger 2002). Tamburri et al. (1996) found that chemical cues successfully induced larval settlement of oysters regardless of flow conditions. In another study, Palmer (1988) showed that higher current velocities increased erosion of small animals from below the sediment surface (meiofauna) into the water column, resulting in increased predation by spot (a more non-visual feeder). Species that rely primarily on visual cues would not be affected by dilution of chemical cues. However, all mobile aquatic organisms (including visual predators) also seek to minimize the energetic cost of movement through the water column while maximizing foraging efficiency.

As fish grow and develop, flow regime requirements or preferences change (Ross and Epperly 1985). Larvae and juveniles generally prefer lower velocities than adults, enabling them to settle out and maintain their positions in the estuary. Consequently, juvenile, estuarine-dependent fish are highly abundant in shallow, side-channel habitats where velocities are low (Ross and Epperly 1985; Noble and Monroe 1991).

There is little information on flow preference of estuarine species. Hydrologic modifications can, in some situations, negatively impact optimum flow conditions for aquatic organisms (refer to threats section for more details). *Research is needed on the preferred flow regimes of estuarine species in order to refine distributional patterns and better understand the effect of hydrological modifications on fish species.*

pH

The pH of the water column is a basic chemical characteristic that affects egg development, reproduction, and the ability of fish to absorb DO (Wilbur and Pentony 1999). Among freshwater, estuarine, and marine systems, pH varies naturally, and the organisms of the aquatic community have adapted to that natural variation. However, most fish require pH >5 (Wilbur and Pentony 1999), within a possible range of 0 (extremely acidic) – 14 (extremely basic). The pH of seawater is the most stable among systems and varies between 7.5 and 8.5 (Nybakken 1993). The pH of estuaries depends on the dynamic mix of seawater and upstream fresh waters. In high-salinity estuaries with little river input (i.e., Core and Bogue Sound), pH is near that of seawater. Fresh water has the most variable pH, depending on the buffering, or acid controlling, capacity of the water and organic matter input. Freshwater water bodies with low buffering capacity and high organic matter (i.e., swampy creeks) can have very low pH (≤5). The pH standard for surface fresh waters in North Carolina is between 6.0 and 9.0. The pH may fluctuate dramatically between day and night, associated with algal blooms. The pH can affect chemical cycling, availability, and ionic balance of compounds within the water column, some of which may be toxic to aquatic organisms under appropriate pH conditions, but have no effect otherwise.

The pH of the water is an important requirement for reproduction of estuarine organisms. For example, the optimum pH for normal egg development and larval growth of oysters occurs between 8.25 and 8.50 (Calabrese 1972; Calabrese and Davis 1966). Oysters also have an optimum pH of 7.8 for spawning and >6.75 for successful recruitment. Likewise, hard clam eggs and larvae require pH levels of 7.0-8.75 and 7.5-8.50, respectively, for the same functions (Funderburk et al. 1991). Anadromous fish species can generally tolerate fresh water with lower pH. For example, alewife eggs and larvae require pH between 5.0-8.5 pH and blueback herring eggs and larvae require pH levels between 5.7-8.5 (Funderburk et al. 1991). This pattern of pH requirements between systems also illustrates the adaptation of freshwater and estuarine organisms to their environment.

2.2. ECOLOGICAL ROLE AND FUNCTIONS

The water column is the lifeblood of aquatic ecosystems. It is the medium through which all other aquatic habitats are connected. As such, the water column provides a basic ecological role and function for organisms within it. The water column also provides other functions, both by itself and due to benthic-pelagic coupling. Benthic-pelagic coupling refers to the influence of the benthic community and sediments on the water column and, in turn, the influence of the water column on them, through integrated events and processes such as resuspension, settlement, and absorption (Warwick 1993).

Productivity

The potential productivity of fish and invertebrates in a system is determined by the assimilation of energy and nutrients by green plants and other life at the base of the food chain. The potential productivity of a habitat can indicate its relative value in supporting fish populations. Although

productivity in the water column is derived mostly from phytoplankton, it can also come from bacterial decomposition of plants (detritus), floating plants, and macroalgae. The foundation of riverine production during elevated flows is detritus from adjacent wetlands and fine particulate organic matter from upstream areas (Vannote et al. 1980; Junk et al. 1989). As flows decline through summer, phytoplankton can maintain its position in the water column and photosynthetic production supports the majority of secondary production. In some coastal rivers (i.e., Perquimans River), floating macrophytes such as duckweed can make up a significant portion of primary production during some years (S. Chappell, DMF, pers. com., 2003). Rivers play a dominant role in providing nutrients and flushing for downstream estuaries in the Albemarle, Tar-Pamlico, Pamlico, Neuse, and Cape Fear management units. These nutrients, in turn, contribute to primary productivity. The amount and type of production are determined by flushing (retention) and season.

Historically, phytoplankton productivity in estuarine systems was thought to be relatively low compared to that of other primary producers (Peterson and Peterson 1979). For instance, Marshall (1970) estimated that phytoplankton contributed only 50 g carbon/m^2/yr to New England's subtidal shoal waters, compared to a contribution of 125 g carbon/m^2/yr for all macrophytes. In the Newport River estuary near Beaufort, North Carolina, Williams and Murdoch (1966) and Thayer (1971) estimated that phytoplankton produce about 110 g carbon/m^2/yr. Subsequent research suggested a higher contribution to overall primary production from phytoplankton (Peterson and Peterson 1979). Sellner and Zingmark (1976) found phytoplankton production as high as 350 g carbon/m^2/yr in shallow tidal creeks and estuaries of South Carolina. Various data sources for North Carolina estimate phytoplankton productivity anywhere from 67 (Beaufort Channel adjacent estuaries) to 500 g carbon/m^2/yr (Pamlico River estuary) during the growing season. Mallin et al. (2000a) found that the highest phytoplankton production is in riverine estuaries where flushing is limited by extensive barrier islands (i.e., Neuse River), whereas areas that are well flushed or unconstrained (i.e., Cape Fear River) support a much lower phytoplankton biomass and productivity. Complex, estuarine creek/salt marsh systems generally have moderate phytoplankton productivity. Lucas et al. (1999) used a depth-averaged numerical model to predict the productivity of phytoplankton in an estuary with shallow shoals, deep channels, and variable turbidity and benthic grazing. The model predicted that phytoplankton growth rate was generally greater in deeper areas when benthic grazing is high and turbidity is low. Conversely, when turbidity was high and benthic grazing was low, phytoplankton growth rate was generally greater in shallow areas.

However, phytoplankton productivity is still generally considered secondary to detritus-based production in salt marsh-dominated estuaries (Peterson and Peterson 1979; Dame et al. 2000). A study conducted on a Georgia salt marsh found a net productivity of 6,850 kcal/m^2/year from emergent vegetation and only 1,600 kcal/m^2/yr from the various algae (Teal 1962). Compared to broad, open water areas, narrow tidal creeks and their associated marsh would likely contribute more detritus than phytoplankton. However, some research suggests that much of the detrital production from emergent vegetation remains in the marsh and that phytoplankton are the major production export (Haines 1979). Planktivorous fish (i.e., menhaden) and detritivores (i.e., shrimp) can also export production from shallow marsh creeks and bays to more open waters (SAFMC 1998).

Phytoplankton production in shallow estuaries may also be secondary to phytobenthic (microscopic plants that live on the bottom) production. In North Carolina, benthic microalgal biomass frequently exceeds phytoplankton in the nearshore ocean water column by a factor of 10 to 100 (Cahoon and Cooke 1992). Based on relative rates of primary production and nutrient cycling, Webster et al. (2002) found that phytobenthos was the dominant primary producer in a shallow estuary where light was not limiting, results that may not be applicable to North Carolina estuaries with higher turbidity. Net productivity for any given estuary depends on the relative proportion of wetlands, shallow soft bottom and water column in the system.

In nearshore ocean waters, the depth that light penetrates to allow photosynthesis (euphotic zone) may be

quite shallow because of high turbidity and wind mixing. Proceeding offshore there is generally a sharp decrease in chlorophyll *a* where the water column becomes more stratified. Menzel (1993) reported that primary production rates decreased significantly from the inner shelf to the outer shelf of the South Atlantic Bight. Production levels may increase by a factor of three to ten with warm core intrusions from the Gulf Stream. Because these intrusions occur irregularly on the inner shelf zone, this nearshore area depends more on nutrients recycled or resuspended by wind or tidal forces (Menzel 1993). Zooplankton distribution is directly related to location of phytoplankton blooms. Cahoon et al. (1990) found that on the inner shelf in Onslow Bay, 80% of the chlorophyll *a* was associated with the sediment. Benthic microalgal biomass (36.4 mg chlorophyll *a*/m^2) always exceeded phytoplankton biomass (8.2 mg chlorophyll *a*/m^2) (Cahoon and Cooke 1992). Hackney et al. (1996) reported that, because of circulation patterns, inorganic nutrients could be resuspended and retained in sufficient amounts to allow localized phytoplankton blooms within the surf zone. Primary production within the water column can also come from macroalgae detached from hard substrate (i.e., *Enteromorpha*) or floating on the surface (i.e., *Sargassum*).

Fish utilization

Although all fish technically use the water column, this section focuses primarily on species associated with open water (pelagic) habitat. Pelagic species are those most commonly found near the surface of the water column and include the adult stages of alewife, American shad, blueback herring, striped bass, bay anchovy, silversides, Atlantic menhaden, bluefish, cobia, Spanish mackerel, and striped mullet. Table 2.5 summarizes the life functions provided by the water column to pelagic fish at various life stages. In addition to these species, eggs and larvae of most fish species depend on the open water for passive transport and food (see Corridor and connectivity function).

Corridor and connectivity

The corridor function is the most basic function of the water column because the various life stages of fish species must move through it to utilize other habitats supporting other functions. The corridor function is particularly important for anadromous species such as river herring, shad, and striped bass, species that must migrate as adults from high-salinity waters, through estuarine waters, and upstream into freshwater systems to spawn in the spring. As a catadromous species, adult American eel must migrate from upstream freshwaters through estuarine waters to their spawning grounds in the Atlantic Ocean. The upstream limit of anadromous and catadromous fish migration in North Carolina is depicted on Map 1.3. All that is needed for transporting anadromous fish eggs and larvae to downstream nursery areas is relatively clear, unobstructed, and flowing water.

Table 2.5. Partial list of important fish and invertebrate species using pelagic habitat in coastal North Carolina, and ecological functions provided for those species. *(Sources: Funderburk et al. 1991, Pattilo et al. 1997, SAFMC 1998, and NOAA 2001)*

The large estuaries of North Carolina function as settling basins where coastal rivers meet the sea (Giese et al. 1979). As such, the flow of water between the rivers and the estuaries, and between the estuary and the ocean, must be maintained so that settlement of transported larvae to the estuary is successful. Nearly all fish and shellfish species in coastal North Carolina occupy the estuarine water column at some point in their life cycle. Meroplankton (organisms that spend only part of their life cycle in the plankton), in particular, rely on the corridor function of the water column to transport them to favorable nursery areas.

The surf zone and shallow intertidal waters are important corridors for seasonal fish migrations and for larval transport in and out of estuarine waters. Several studies have directly targeted surf zone fishes in North Carolina (Francesconi 1994; Hackney et al. 1996; Ross and Lancaster 1996). These studies reported 47 species in North Carolina's surf zone. About 130 species of fishes have been reported from North Carolina through Georgia (Tagatz and Dudley 1961).

Common species inhabiting the Surf Zone
Atlantic menhaden, striped anchovy, bay anchovy, rough silverside, Atlantic silverside, Florida pompano, spot, Gulf kingfish, striped mullet, and Spanish mackerel, flounders, bluefish, Atlantic sharpnose shark, red drum

The surf zone is an important migratory path for larval and juvenile fish moving toward the estuaries in the winter and spring. Adult fish are thought to migrate close to shore in the surf zone during the fall migration offshore (Hackney et al. 1996). Adult fish abundance in the surf zone is highly seasonal with lowest abundance and diversity in the winter and maximum abundance and diversity in the late summer (Hackney et al. 1996). Maximum biomass occurs in the fall when juveniles are at peak sizes, and large schools of fish migrate from the estuaries along the beaches. Table 2.5 provides information on habitat utilization of some of the most important fishery and prey species in the water column.

Larval fish are an important component of zooplankton in the coastal ocean water column. In Onslow Bay, Powell and Robbins (1998) documented a total of 110 families from ichthyoplankton samples. Estuarine-dependent species such as menhaden, spot, and Atlantic croaker are an important component of the ichthyoplankton during late fall and winter. These species spawn offshore and must be transported into estuaries through the water column. Ichthyoplankton from estuarine-dependent species that spawn in the sounds, inlets, and nearshore ocean waters during spring and early summer (i.e., pigfish, silver perch, weakfish) were also found in the ocean water column shortly afterward. Reef fish larvae were most abundant during spring, summer, and early fall. The frequent occurrence of larvae from deep-water oceanic species indicates that Gulf Stream waters transported those larvae to shelf waters off North Carolina.

Inlets are important corridors (or bottlenecks) through which many fish must successfully pass to complete their life cycles. Larval fish diversity in North Carolina's inlets is very high. Sixty-one larval species have been found in Oregon Inlet; Atlantic croaker and summer flounder were particularly abundant (Hettler and Barker 1993). Some of the other species included bluefish, black sea bass, gray snapper, several flounder species, pigfish, pinfish, spotted seatrout, weakfish, spot, kingfish, red drum, mullet, and butterfish. Beaufort, Ocracoke, and Oregon inlets also support significant larval fish passage, although Oregon Inlet may be especially important due to the great distance between it and adjacent inlets, its orientation along the shoreline, and the direction of prevailing winds. Oregon Inlet provides the only opening into Pamlico Sound north of Cape Hatteras for larvae spawned and transported from the Mid-Atlantic Bight.

Peters et al. (1995) and Peters and Settle (1994) documented species' utilization and temporal trends in larval fish transport through Beaufort Inlet. Table 2.6 depicts the time periods during which various larval species immigrated through the inlet. Over 52 taxa including 29 species were identified, although menhaden, spot, Atlantic croaker, and pinfish dominated the majority of the samples. Peak larval abundances for those species occurred between September and April.

Research projects conducted under the South Atlantic Bight Recruitment Experiment (SABRE) studied transport of winter-spawned fish larvae into the estuaries. Larvae concentrate on the shelf in a narrow "withdrawal zone" upwind of an inlet within the 23-foot (7m) deep isobath. Upon the appropriate conditions of ocean currents, the larvae pass through the inlets. Even during best wind and tidal conditions, only about 10% of the available larvae are successfully drawn into the inlet (Blanton et al. 1999). Larvae passing downwind and outside the narrow withdrawal zone pass seaward of the inlet shoals and, given the right conditions, will be transported into the next available inlet downstream. Churchill et al. (1999) noted that transport dynamics in the immediate vicinity of inlets are complex, and that larvae may also remain near an inlet or move in and out repeatedly before actually immigrating. However, since the along-shore flow component of the coast is four to five times greater than the cross-shelf component, larvae are highly dependent on being transported along the shore in a narrow zone and then injected through the inlet (Hare et al. 1999). Offshore-spawning, estuarine-dependent species include many of North Carolina's most important commercial and recreational fish species, such as menhaden, spot, Atlantic croaker, pinfish, flounders, shrimp, black sea bass, and gag. Red drum and blue crabs, which spawn in and near the inlets, also require transport of larvae through inlet systems. Consequently, successful movement of larvae through the inlets is of great importance to North Carolina fisheries, particularly where inlets are limited, such as along the Outer Banks.

Spawning

Fish that spawn in open waters generally broadcast planktonic eggs. Survival of these eggs is affected by flow and circulation patterns. With increasing light, flow, and temperature during the spring, open-water freshwater systems provide spawning habitat for resident freshwater and anadromous fish (Orth and White 1993). Anadromous fish species such as river herring (alewife and blueback herring), striped bass, and shads (hickory and American shad) use the freshwater water column to broadcast eggs which develop as they float downstream. All of the life stages of these species use the water column as their primary habitat. Environmental conditions such as heavy rainfall, high water flow, and temperature affect anadromous fish life cycle stages and migration patterns in freshwater systems. Conditions for anadromous fish spawning are typically met from mid-February to mid-June in North Carolina (Table 2.7), although spawning periods vary according to species and drainage basin (Steel 1991).

Sufficient rainfall is needed to provide suitable current velocities for spawning. The strongest currents are required by striped bass and blueback herring (Table 2.8). Slower current velocities are needed for American shad and alewife; alewife spawn in slow-moving oxbows and small streams, as well as fast-water sites. Adequate DO levels in slow-moving backwaters are critical to alewife spawning because the eggs require >5 mg/l DO (Funderburk et al. 1991) (Table 2.4). During their spawning migration, anadromous fish actively avoid waters with low DO and extremely high turbidity (Steel 1991).

Estuarine spawners fall into two basic groups, estuarine spawning species and inlet/estuarine channel spawning species. The estuarine spawning species are mostly resident forage finfish species that spawn

in shallow water during the warmer months (Table 2.7). This group also includes some important shellfish species (i.e., oysters, hard clams, bay scallop). Spawning for oysters, clams, and scallops is triggered primarily by increasing water temperatures during spring and/or decreasing water temperatures in fall (Fay et al. 1983c; Burrell 1986; Eversole 1987). Table 2.7 shows spawning seasons for coastal fish and invertebrate species found in North Carolina waters. The specific time of spawning for anadromous fishes is determined by coincidence of physical conditions in the water column (Table 2.8).

The inlet/estuarine channel spawning group includes mostly large fish species such as weakfish, red drum, and cobia that spawn in or near deep flowing waters. The environmental requirements for successful spawning and egg development for estuarine spawners are shown in Table 2.9.

The marine spawning species generally spawn in locations where prevailing currents will carry their eggs and larvae to nursery areas within estuaries and nearshore ocean waters. Spot, Atlantic croaker, southern flounder, Atlantic menhaden, and striped mullet spawn offshore where they produce planktonic eggs and larvae from fall to late winter (Table 2.7) (Anderson 1958; Epperly and Ross 1986). Their larvae are transported into the estuaries where they settle in nursery areas with low to moderate salinity. The spawning function of pelagic waters for demersal species is therefore limited to egg dispersal (discussed in Corridor section). The specific time of spawning is determined by coincidence of environmental conditions in the water column (Table 2.10). The other group of marine spawners reproduces at various times, but their nursery habitat is limited to higher salinity areas.

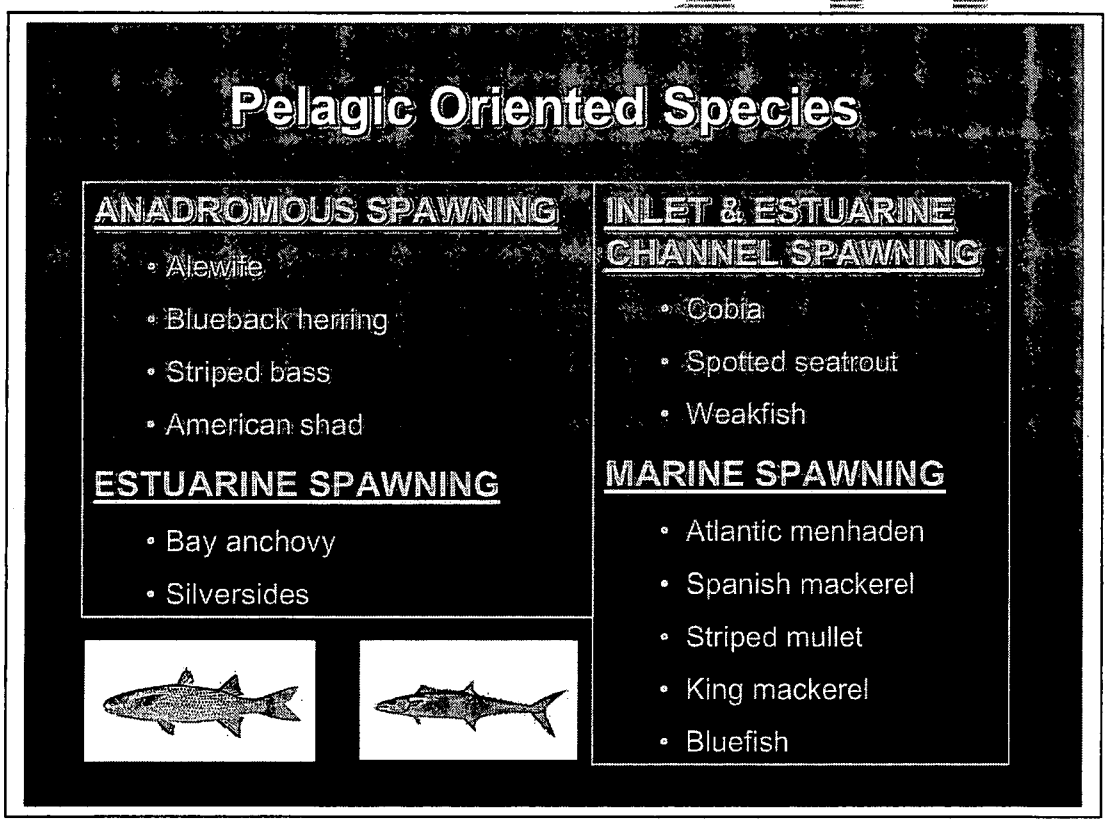

Table 2.7. Spawning seasons for coastal fish and invertebrate species occurring in North Carolina that broadcast planktonic or semidersal eggs.

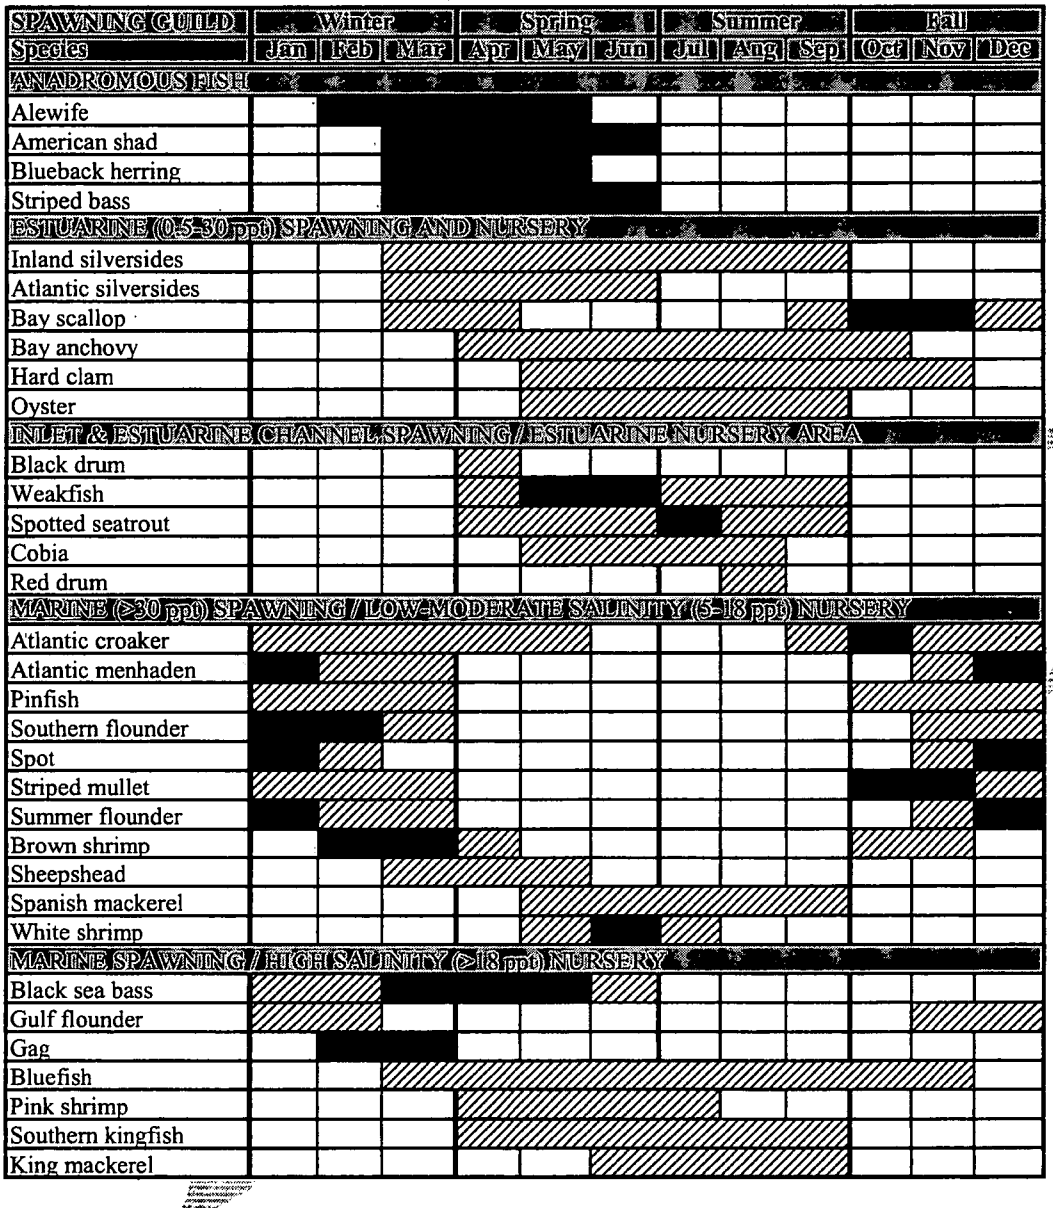

Black squares indicate peak spawning. **Cross-hatched** squares indicate spawning period.

Nursery

Open water provides nursery habitat for most planktivorous larvae and many juvenile pelagic species (i.e., bluefish, river herring, menhaden, Spanish mackerel). The value of open water habitat for these species depends on the abundance and timing of planktonic food sources and their coincidence with required environmental conditions needed for growth during this critical time period. Areas that have been designated as Primary, Permanent Secondary, or Special Secondary Nursery Areas by the Marine Fisheries Commission are shown in Map 2.3a-b and total approximately 162,300 acres of coastal waters. Of this total, roughly 80,800 acres are Primary Nursery Areas, 35,000 acres are Permanent Secondary Nursery Areas, and 46,500 acres are Special Secondary Nursery Areas.

Anadromous fish nurseries

Nursery habitat for anadromous fishes is generally downstream from spawning locations but still within the freshwater low-salinity system. Alewife larvae in the Chesapeake Bay moved slightly downstream from spawning areas only where salinities were less than 12 ppt (Fay et al. 1983d). Juvenile alewife and blueback herring in the Potomac River exhibited apparent upstream movement over the four months before emigration. Both species were most abundant in surface waters through September. Juvenile blueback herring remained in the upper portion of the water column during their stay in nursery areas. Juvenile alewife, however, increased in abundance at a depth of 15 feet (4.6 m) and on the bottom for the two months prior to emigration (Warinner et al. 1969).

Juvenile alewife and blueback herring emigrate from freshwater/estuarine nursery areas by November of their first year of life (Burbidge 1974; Kissil 1974; Richkus 1975; O'Neill 1980). Heavy rainfall, high water flow, and sharp declines in water temperature have been found to influence the initiation of migration from nursery areas (Cooper 1961; Kissil 1974; Richkus 1975). The water quality requirements for anadromous fish larvae and juveniles inhabiting pelagic waters are listed in Table 2.11.

Table 2.11. Larval and juvenile water quality requirements for anadromous fish species inhabiting coastal North Carolina.

[S] = suitable, [O] = optimum
[Source: NOAA 2001, Funderburk et al. 1991, SAFMC 1998, Pattilo et al. 1997, USFWS species profiles (see literature cited: reference titles beginning with Species life histories and Environmental Requirements), and Wannamaker and Rice 2000]

Larval striped bass move downstream from spawning locations in the upper river during summer and early fall, where they inhabit shoal waters less than six feet deep (Funderburk et al. 1991). As the larvae grow into juveniles, they move progressively downstream, where they seem to prefer shallow-water, nearshore areas (Funderburk et al. 1991). During winter, young striped bass may move farther downstream and into deeper water (Kay et al. 1983a; Hill et al. 1989).

Juvenile American shad use the same general nursery areas as river herring, but the young shad prefer deeper pools away from the shoreline and occasionally move into shallow riffles (Funderburk et al. 1991). During summer, juvenile shad migrate from the bottom during the day to the surface at night (Loesch and Kriete 1984). A decrease in temperature during the fall and slight increases in river flow seem to trigger downstream movement of American shad (Funderburk et al. 1991). Nursery area surveys conducted by DMF noted decreased catch of juvenile shad in October on the Cape Fear River, Neuse River, and Albemarle Sound (Winslow 1990a).

Low-moderate salinity nurseries

The interactions of spawning locations, physical processes, environmental factors (salinity and temperature), chemical cues, and habitat preferences are determining factors for the time and place of larval settlement in estuaries (Brown 2002; Luckenbach 1985; Peterson et al. 2000c). The total nursery area for larvae of most estuarine-dependent species extends from the spawning locations to juvenile nursery habitat. For species spawned offshore in winter, the larval (primary) nursery habitat extends from the inlet water column, across primarily inshore-flowing channels, to the upper reaches of estuaries. Survival to the juvenile life stage and beyond is then dependent on the estuarine nursery areas providing the biological, physical and chemical characteristics needed for growth (Table 2.12).

In the Pamlico Sound, salinity and circulation patterns are the key physical conditions affecting the species composition occurring in juvenile nursery habitat (Noble and Monroe 1991). Low-salinity nurseries include the Pamlico, Pungo, and Neuse rivers, the eastern portion of Albemarle Sound (including Croatan and Roanoke sounds), and the upper Cape Fear estuary. During spring through fall, shallow areas within these systems are dominated by juvenile Atlantic menhaden, striped mullet (Epperly

and Ross 1986), silversides, anchovies (Nelson et al. 1991), and demersal species such as Atlantic croaker, brown shrimp, blue crab, and southern flounder (Noble and Monroe 1991).

Table 2.12. Water quality requirements for selected larval and juvenile estuarine fish species inhabiting low-moderate salinity (0.5-18 ppt) open water habitat in coastal North Carolina.

[Source: NOAA 2001, Funderburk et al. 1991, SAFMC 1998, Pattilo et al. 1997, USFWS species profiles (see literature cited: reference titles beginning with Species life histories and Environmental Requirements), and Wannamaker and Rice 2000]

Moderate-salinity areas include the bays and open waters of Pamlico Sound. In addition to juvenile species present in lower salinity areas, spotted seatrout, weakfish, silver perch, and red drum are also abundant in these moderate-salinity estuaries (Noble and Monroe 1991). Young weakfish and silver perch tend to occupy deeper waters of the moderate and high-salinity zones, while young blue crabs and other demersal species prefer shallow areas (Epperly and Ross 1986). There seem to be little or no data on the depth distribution for juvenile spotted seatrout in North Carolina. However, information from the Gulf coast suggests that the species prefers shallow, sheltered waters (Blanchet et al. 2001). The most common characteristics of water bodies supporting juvenile red drum in North Carolina are water depth (<16 feet or <5 m) and relative wind protection (Ross and Stevens 1992).

Different species arrive in nursery areas at different times of the year and remain for variable periods. For

example, juvenile spot begin entering nursery areas in February (Steel 1991). Postlarval Atlantic croaker arrive over an extended period from August to May, with peak recruitment during winter and early spring (Purvis 1976). Similar to Atlantic croaker, postlarval striped mullet enter low-salinity nurseries primarily in winter (Nelson et al. 1991). Menhaden postlarvae arrive in low-moderate salinity nurseries from February to June (Purvis 1976), whereas juvenile anchovies and silversides are generally year-long residents (Nelson et al. 1991). Juvenile brown shrimp are most abundant in moderate-salinity nurseries during spring to early fall (Nelson et al. 1991), migrating to higher salinity areas as they grow larger. By late fall, many of these nonresident estuarine fish migrate to the ocean or to deeper regions of the estuary to overwinter (Epperly and Ross 1986).

High-salinity nurseries

High-salinity nurseries (>18 ppt) include the eastern side of Pamlico Sound, Core and Bogue sounds, the mouth of the Cape Fear River, and the southern coastal estuaries. The dominant juvenile species in shallow waters of the high-salinity zone include pinfish, pink shrimp, black sea bass, gag, pigfish, red drum, gulf flounder, and summer flounder (Noble and Monroe 1991). Juvenile spot, brown shrimp, striped mullet, and southern flounder are also abundant in high-salinity estuaries (Epperly and Ross 1986), and juvenile red drum reach their highest abundance in this salinity zone (Nelson et al. 1991). With the exception of summer flounder (Powell and Schwartz 1977), these high-salinity species prefer protected, shallow waters over deeper areas. However, young Spanish mackerel, bluefish, and cobia prefer deeper, more open waters (NOAA 2001). The water quality requirements for larvae and juvenile species inhabiting open waters of the high-salinity zone are listed in Table 2.13. As with juveniles in lower salinity areas, the timing of juvenile arrival in high-salinity nurseries depends on their preceding spawning conditions. Bluefish begin spawning in March, and their young become abundant in Bogue Sound (a high-salinity estuary) around mid-May (Nelson et al. 1991). Juvenile pinfish spawned offshore in winter become abundant in Bogue Sound by late March, and juvenile sheepshead spawned later in winter and early spring become abundant in Bogue Sound by April (Nelson et al. 1991). Spanish mackerel appear (although rarely) in Bogue Sound in mid-May (Nelson et al. 1991).

Data from the Estuarine Trawl Survey indicate that the diversity of juvenile species found in designated primary nursery areas is somewhat larger in waters north of Cape Lookout than south of Cape Lookout. From 1990 to 2002, an average of 68 species was collected from core sampling stations north of Cape Lookout during the months of May and June. During the same time span, an average of 55 species was collected south of Cape Lookout (DMF, unpub. data). The greater diversity in northern waters may be due to the larger variation in salinity regimes or its location at a major transition point for species distribution. North of the cape, the total number of observed species generally changed by less than 10 species from year to year. The number of species collected was lowest in 1992 (49 species) and highest in 1998 (83 species). Annual changes in observed species diversity south of Cape Lookout also appear to be relatively consistent (45 and 49 species were collected in 1999 and 2001, respectively).

Bluefish, Florida pompano and Gulf kingfish use the surf zone and nearshore ocean waters as a nursery (Hackney et al. 1996). Juveniles of these species tend to stay in one area and use the surf zone for an extended time (>25 days during the summer months) (Ross and Lancaster 1996). Some fish, such as anchovies and king mackerel, rely on the nearshore boundaries of ocean water masses as nursery habitats (SAFMC 1998). Juveniles of other estuarine species, such as red drum, Spanish mackerel, bluefish, and black sea bass, use the surf zone and nearshore waters seasonally while migrating between estuarine and ocean waters (Godcharles and Murphy 1986; DMF 2000a). Pelagic species that use nearshore ocean waters as a nursery to some extent include butterfish, pinfish, striped anchovy, striped mullet, and Atlantic thread herring (F. Rohde, DMF, pers. com., 2001). The major recruitment period for juvenile fish to surf zone nurseries is late spring through early summer.

Table 2.13. Water quality requirements of selected larval and juvenile coastal estuarine fish species inhabiting high-salinity open water habitat in coastal North Carolina.

Species	Salinity (ppt)		Temperature (C)		Dissolved oxygen (mg/l)	
	Larvae	Juvenile	Larvae	Juveniles	Larvae	Juvenile
Bay scallop	**[S] 22-35 [O] 25**	[S] 16-30	**[S] 16-30**	[S] 11 to >30

Foraging

The primary food sources abundant in open waters are decayed plant material (detritus), phytoplankton and zooplankton. Most fish, during the larval stage in particular, consume plankton at some point in their life cycle. Of the 43 species listed in Table 2-3, nearly all larval stages eat phytoplankton or zooplankton. Resuspended benthic microalgae are also an important source of food.[2] The diet of juveniles and adults includes zooplankton (the relatively most common component), detritus, or phytoplankton (the least common). In addition, pelagic fish may consume benthic copepods, mysids, and amphipods as they rise through the water column at night (P. Peterson, UNC-IMS, pers. com., 2003). Some adult fish also forage on other fish. Overall, about 60% of juvenile species and 50% of adult species listed in Table 2.3. eat detritus, phytoplankton, zooplankton, or fish eggs/larvae (NOAA 2001).

In low-salinity estuaries and riverine systems, tributaries are the dominant source of water inputs. Because of this, the foundation of the food chain is typically incoming detritus from the watershed (Fairbanks 1963). Detritus comprises a large portion of the diet of small animals in the water column and on the bottom; these animals are in turn eaten by larger organisms. Estuarine and riverine fish can be characterized as omnivores and opportunistic feeders. Many fish, including the anadromous species, shift their food preferences as they grow. Most of the prey species important to finfish live in the water column. Some of the pelagic estuarine fish that feed on other fish in the water column include weakfish, bluefish, Spanish mackerel, and cobia (NOAA 2001).

Within an estuary, menhaden, anchovy, silversides, striped mullet, and other pelagic species use suspended organic matter exported from the adjacent marshes, SAV, and oyster reefs without physically occupying these structured bottom habitats (SAFMC 1998). The relative contributions of detritus and phytoplankton between the estuarine and nearshore ocean ecosystem are demonstrated by the foraging behavior of Atlantic menhaden. Lewis and Peters (1994) confirmed that the dominant food source for

[2] Refer to the soft bottom section for more information on how soft bottom habitat contributes to water column productivity through benthic-pelagic cycling.

menhaden was detritus in shallow, estuarine systems, but phytoplankton in coastal waters.

A large number of fish inhabits the marine water column as adults. Coastal pelagics, highly migratory species, and anadromous fish species are dependent on the water column for adequate foraging. The boundaries of water masses (coastal fronts) in the nearshore ocean are favorite foraging areas for mackerel and dolphin (SAFMC 1998). King and Spanish mackerel feed on baitfish that congregate seasonally on shoals and natural and artificial reefs. National Marine Fisheries Service (SAFMC 1998) has designated the cape shoals of North Carolina as Habitat Areas of Particular Concern (HAPC) for both mackerels. Anadromous species such as shad, river herring, and striped bass utilize the cape shoals as a staging area for migration along the coast. Large aggregations of striped bass have been documented in the northern, nearshore coastal area of the state during winter months, feeding and resting prior to initiation of an extensive northward spawning migration (Laney et al. 1999; Holland and Yelverton 1973). This wintering ground is shared by the Chesapeake, Hudson, and Roanoke/Albemarle striped bass stocks, and is therefore important to the entire Atlantic coast population (Benton 1992). The water column off the Outer Banks during winter supports an abundance of anchovies and menhaden, weakfish and other sciaenoids, on which the striped bass feed. Laney et al. (1999) considered the existence of an area with such abundant food sources to be critical for building energy reserves for successful migration and reproduction of striped bass.

Refuge

The water column provides a basic, but relatively minor, function as refuge for adult finfish and invertebrates. However, the water column does provide some indirect protection for forage species that need unobstructed, open water for protective schooling behavior (Table 2.5). For example, silversides can create such dense schools that DO concentrations are low enough to repel predators (Fay et al. 1983b). Other areas of low DO can provide refuge for prey species whose predators are less tolerant of low DO. For example, copepods and zooplankton have a high tolerance for low DO, which could impact the food web in areas where the small invertebrates use low DO areas for refuge (Breitburg et al. 1997; Keister et al. 2000). Large expanses of open water can also provide protection for forage species by reducing their encounters with predators. Turbidity in the water column can provide prey species refuge from visual predation (Bruton 1985) (refer to Light and water clarity section above). For example, bay anchovy may be attracted to more turbid areas for the refuge it provides (Livingston 1975). Snags from woody debris or overhanging branches extending from the shoreline provide excellent refuge for fish.

Deep water provides an important refuge from birds that feed in shallow water and protection from colder surface temperatures during winter. Deep, open-water habitats also provide refuge for fish and invertebrates during low tide (Ayvasian et al. 1992). Floating aquatic plants in fresh water such as duckweed may provide refuge for some open water fish. The value of floating plants has been evaluated in marine systems, where *Sargassum* floating in the water column supports a diverse assemblage of marine organisms, including at least 145 species of invertebrates, 100 species of fish, four species of marine turtles, and numerous marine birds (SAFMC 1998). *Sargassum* is concentrated as small patches, large rafts, or weedlines at the convergence of water masses in the coastal ocean, such as those found along "tide lines" near coastal inlets. The greatest concentrations of *Sargassum* patches are found in the Sargasso Sea and on the outer continental shelf of the South Atlantic, although they can be pushed into nearshore waters by winds and currents. Large pelagic adult fish such as dolphin and sailfish feed on the small prey in and around *Sargassum*. This behavior prompts sport fishermen to target *Sargassum* patches.

Areas within the water column that have been found to have a particularly important ecological role or function include inlets, shallow nursery areas, and the nearshore surf zone. *These areas and others should be considered for designation as Strategic Habitat Areas.*

2.3. STATUS AND TRENDS

In North Carolina, news of massive fish kills, increasing events of oxygen depletion and harmful algal blooms caused widespread concern over water quality and fisheries between the late 1980s and late 1990s. The catastrophic events that made news headlines have abated, but the concern over coastal water quality has not disappeared. There are many indications from a variety of sources that the nation's overall water quality is becoming increasingly degraded over time (EPA 2002; Heinz Center 2002). In a recent EPA report on national water quality, using data through 2000, more than one third of the surveyed rivers and one half of all lakes and estuaries were too polluted for swimming or fishing (EPA 2002; <http://www.epa.gov/305b/>, 2003). From 1998 to 2000, the percent of polluted streams increased from 35% to 39% and the percent of polluted estuaries increased from 44% to 51%.

This section briefly describes ongoing water quality and fishery monitoring programs that help determine the status and trends of water column habitat in North Carolina. Status and trends are described in terms of physical and chemical conditions (such as salinity and the presence of nutrients) and fisheries associated with the open water subsystem of water column (i.e., bluefish, Atlantic menhaden).[3]

Physical and chemical environment

Although water quality monitoring data are abundant for North Carolina, differences in sampling methodology, such as duration, magnitude, and parameters studied, complicate comparisons within and among river basins over time. However, information obtained from ongoing state and federal programs allow for some indirect evaluations. At the coast-wide level, water quality evaluations are conducted by DWQ and USGS. Detailed information on water quality within specific coastal river basins is available from DWQ's basinwide water quality plans (<http://h2o.enr.state.nc.us/basinwide/index.html>, 2004).

Statewide and regional water quality monitoring

The status of water quality conditions in North Carolina's coastal waters, as well as the probable causes of water quality problems, is determined primarily by DWQ's use support assessments. Water quality data are collected and summarized by river basin on five-year cycles. The information is used to assess whether waters are supporting their designated use (Use Support). Surface waters are assigned a use support status based on assessment of DWQ's biological sampling (benthic macroinvertebrates and fish); chemical and physical data from surface water monitoring; lake monitoring data; shellfish sanitation surveys; and other information. Impaired waters do not meet one or more water quality standards or some other criterion. If data are inconclusive for a determination of use support, the water body is not rated. If no data are available, the water use support status is "no data."

Because of changes in methodology and in EPA requirements for assessing use support and improvements in analytical methodologies, current use support ratings cannot be directly compared to previous assessments, and trends cannot be readily identified. Division of Water Quality use support assessments give a snapshot of recent water quality conditions and can be used to determine where further studies or different management strategies are needed (DWQ 2000a). The DWQ Use Support status of water bodies is referred to throughout this document as a general indicator of the current condition of some North Carolina coastal waters.

The DWQ use support information reported in this document is taken from the 1998-1999 305(b) report (DWQ 2000a). In this report only one overall use support rating was given for individual water bodies. However, beginning with the 2000 Roanoke River Basin Plan, use support ratings are separated into six categories where applicable. Because of the rotation of river basin plan development, not all river basins have been assessed with this different methodology. Therefore the 2000 305(b) report was used in the

[3] Further information on threats and specific trends in water quality parameters is discussed in the threats section.

CHPP to briefly summarize and compare the general condition of all coastal river basins at one time period. Water quality data will be updated when the CHPP is updated.

The U.S. Geological Survey's National Water-Quality Assessment (NAWQA) was established in 1991 to evaluate the condition of the Nation's estuaries. The Albemarle-Pamlico Study Unit was one of 20 study areas evaluated nationwide. Data for the Albemarle-Pamlico study unit provide an assessment of water quality within each study unit by analysis of historical (pre-1992) and current (1992-95) water quality information. Surface water samples collected from the Coastal Plain and Piedmont and ground-water samples from the Coastal Plain of the Albemarle-Pamlico drainage area were analyzed to characterize current water quality conditions in the basin and identify potential problems in the study area. Because of potential human health and environmental implications, nutrients (nitrogen, ammonia, and phosphorus) and pesticides were the primary focus of the NAWQA effort (refer to Threats section). The study found that, although the water quality conditions tended to be more degraded than the national average, the fish communities were less degraded than the national average. This inconsistency could indicate that inappropriate measures were used to calculate a national fish community index, fish communities in the North Carolina study areas were relatively tolerant to water quality degradation or there were flaws in the water quality testing.

Freshwater and estuarine water quality

As of 2002, surface water quality monitoring stations for freshwater areas within the CHPP area include approximately 145 DWQ ambient stations, 104 USGS stream gauges, 91 NAWQA stations, and 41 Citizen's Water Quality Monitoring Stations (Table 2.14, Map 2.8). Based on total watershed land areas, the mostly heavily sampled freshwater areas are located in the Neuse, Tar-Pamlico, and Cape Fear management units.

Table 2.15 shows the extent to which North Carolina's coastal rivers are able to support their intended uses. Of the total 15,771 freshwater stream miles in coastal river basins, 12,456 miles (94%) were rated by DWQ during 1995-1999. Of the 94% that were rated, 89% were fully supporting their intended uses; seven percent of streams were partially supporting and 1% were not supporting (DWQ 2000a). Current Use Support Assessments by DWQ do not use the "partially supporting" category. Of all monitored and evaluated streams, the river basin with the lowest percentage of fully supporting streams was the Chowan (42%). However, only about half of the stream waters were evaluated in the Chowan river basin primarily because of problems evaluating swamp waters. Recent refinements in the classifications of swamp waters in the Chowan River basin suggest less impairment (DWQ 2001a).[4]

Use-support evaluations in estuaries are based on 119 DWQ ambient stations, nine USGS stations, 31 Citizen's Water Quality Monitoring Stations, and other information sources (discussed below in Threats section). The typical coverage of monitoring stations in estuarine systems is somewhat less than in freshwater streams, particularly in Pamlico Sound, which has only five monitoring stations (Table 2.14). However, it is noteworthy that there are 1,263 DEH bacterial contamination-monitoring stations, which are often the primary basis for use-support ratings in estuaries (P. Fowler, DEH, pers. com., 2002). These DEH stations could provide a more balanced picture of coastal water quality than the lack of estuarine monitoring stations implies (to the degree that fecal coliform contamination indicated other forms of degradation). *There is a need to coordinate and enhance water quality, physical habitat, and fisheries resource monitoring efforts by DWQ, DMF, WRC, USFWS, USGS, NMFS, DEH, and others to determine status and trends of coastal waters and resources. There should also be concurrent efforts to provide a more thorough analysis of existing water quality data at multiple spatial and temporal scales.*

[4] Sources of impairment are discussed in the Threats section.

Table 2.14. Number of freshwater and estuarine surface water quality monitoring stations in North Carolina coastal drainages (as of 2002). The limit of estuarine waters was depicted using the spatial component of the salinity zone data presented in Table 2.2.

Management unit	Number of stations (freshwater/estuarine)						TOTALS	
	DWQ ambient stations	USGS Stream gauge	USGS Water quality	USGS Gauge + water quality	Citizens monitoring sites	Other	freshwater stations	estuarine stations

Total	15,771	11,141	89	1,083	9	232	2	3,315	6

Note: DWQ no longer differentiates a "partially supporting" category, so data are not comparable with more recent data.

Table 2.16. Use Support status for estuaries in each coastal river basin (1995-1999).

River Basin	Total acres	Use Support Totals (Miles)							
		Fully Supporting	% of rated	Partially Supporting	% of rated	Not Supporting	% of rated	Not Rated	% of total
Cape Fear	39,200	29,673	76	8,602	22	0	0	0	0
Lumber	4,800	2,178	45	2,622	55	0	0	0	0
Neuse	328,700	296,162	90	32,538	10	0	0	0	0
Pasquotank	868,800	862,813	99	5,987	1	0	0	0	0
Tar-Pamlico	634,000	622,420	99	8,280	1	0	0	3,300	1
White Oak	121,875	109,934	90	11,941	10	0	0	0	0
Total	**1,997,375**	**1,923,180**	**96**	**69,970**	4	**0**	0	**3,300**	0

Note: DWQ now evaluates 6 separate use support rating categories for each river basin and has changed the use support classifications, so data are not comparable with more recent data.

Based on use-support ratings, the water quality of estuaries in North Carolina was considered in overall good condition in 1999 (DWQ 2000a). According to the DWQ 305(b) Report (DWQ 2000a), 96% of North Carolina estuaries were rated as fully supporting, with only 4% rated as partially supporting (Table 2.16). However, several changes in the use support assessment methodology will result in a substantial number of SA waters being downgraded to impaired for shellfish harvesting use support. The only ratings now used are fully supporting or impaired. Conditionally approved waters that in the past were rated as "fully supporting but threatened" or "partially supporting" are now rated as impaired. As an example, from 1995-1999, 10% of the rated waters in the White Oak River basin were classified as partially supporting and 0% were classified as not supporting for overall use support; whereas in 2001, 24% were rated as impaired for shellfish harvest use support. The increase is primarily attributed to the change in methodology, rather than additional shellfish closures.

Ocean water quality

There are a limited number of water quality monitoring stations in North Carolina's ocean waters. Since 2000 the University of North Carolina at Wilmington has maintained eight water quality monitoring stations in Onslow Bay and seven stations in Long Bay through the NOAA-supported Coastal Ocean Research and Monitoring Program (CORMP). There are also four NOAA Coastal-Marine Automated Network (C-MAN) stations in our coastal waters. The C-MAN stations are permanent automated climatic stations that typically record barometric pressure, wind direction, speed and gust, and air temperature. However, some C-MAN stations also measure seawater temperature, water level, wave height, relative humidity, precipitation, salinity, underwater light availability, and visibility. In North Carolina state waters, the only C-MAN station that measures water temperature is located off Cape Hatteras (see <http://www.ndbc.noaa.gov/Maps/Southeast.shtml>, 2003, for list of parameters measured by each C-MAN station). The EPA has three water quality sampling stations off the Outer Banks of North Carolina located approximately five nm off Currituck Beach, Sanderling, and Kitty Hawk. Parameters measured biannually since 1999 include total phosphorus, total nitrogen, chlorophyll *a*, and visibility (G. Gibson, EPA, pers. com., 2001). *To improve our understanding of current conditions in coastal waters, and the effect of estuarine inputs and human activities, water quality monitoring and research on coastal processes in North Carolina's nearshore ocean waters is needed.*

In 1997, the Division of Environmental Health, Shellfish Sanitation Office began a recreational swimming water quality-monitoring program. The purpose of the program is to test for bacterial contamination (total coliform, fecal coliform, and *E. coli*) to determine safety for swimmers. Bacterial

contamination often comes from stormwater discharges along the ocean beaches. There are 33 ocean sampling stations in the northern region, 13 stations in the central region, and 22 in the southern section (Map 2.9a-c). Samples are taken from the surf zone where the public frequently swims. Stations are located near known stormwater outfalls and populated beach communities. In general, the results of the sampling have been within the SB water quality standards (<geometric mean of 200/100 ml MF fecal coliform). It has been necessary, however, to post temporary precautionary swimming advisories along the coast following heavy rain events because of potential contamination from stormwater discharge onto the beach or water.

Fisheries associated with pelagic habitat

Trends in fish abundance may be an indication of changes in water quality. The status and trends of some open water fishery species are described in Table 2.5. Because many variables affect fish abundance, trends in stock status do not necessarily indicate a corresponding trend in water quality. The data necessary for evaluating trends in species abundance come from several sources:

- Fisheries-dependent data on commercial catch and effort (beginning in 1994 with the DMF trip ticket program).
- Fisheries-dependent data on commercial catch from fish house samples (since 1972 for many species).
- Creel survey data on recreational catch collected by NOAA (since 1979) and by DMF (since 1987).
- Fisheries-independent data from several coast-wide biological surveys (conducted by DMF from the early 1970s to the present).

The objective of these programs is to obtain biological and fisheries data on economically important fishes for use in fishery management decisions. Long-term trends in length, weight, and age for each stock are analyzed. The data collected provide information on species composition, relative abundance, distribution, migration, and seasonality of various fisheries. In riverine and estuarine waters, sampling focuses on juvenile estuarine and anadromous fish species, although data on adult fishes are collected from several fisheries. In ocean waters, the primary commercial fisheries sampled include the winter trawl (flynet and flounder trawl) and sink net fisheries. Other programs collect information on the snapper-grouper, coastal pelagic, red drum, beach seine fishery, other fisheries, as well as catch and effort data. The information from the sampling programs is used in conjunction with commercial fishery landings data and recreational fishing surveys to evaluate stock status of important fishery species and to prioritize development of state fishery management plans. A stock status report is issued annually by the DMF.

Of at least fifteen pelagic species identified in Table 2.5, nine species, comprising at least eleven stocks, were evaluated for fishery status. Of the ten stocks whose status was known, two were designated as overfished (20%), two as concern (20%), one as recovering (10%), and five as viable (50%) (DMF 2003a, Figure 3.4). Specifically, the Albemarle Sound stock of alewife and blueback herring (classified jointly as "river herring" in the stock status report) and the Central/Southern stock of striped bass were listed as "overfished", while the stocks of American shad and striped mullet were identified as "concern." Viable stocks included those of Atlantic menhaden, Spanish mackerel, king mackerel, and striped bass in the Atlantic Ocean and Albemarle Sound.

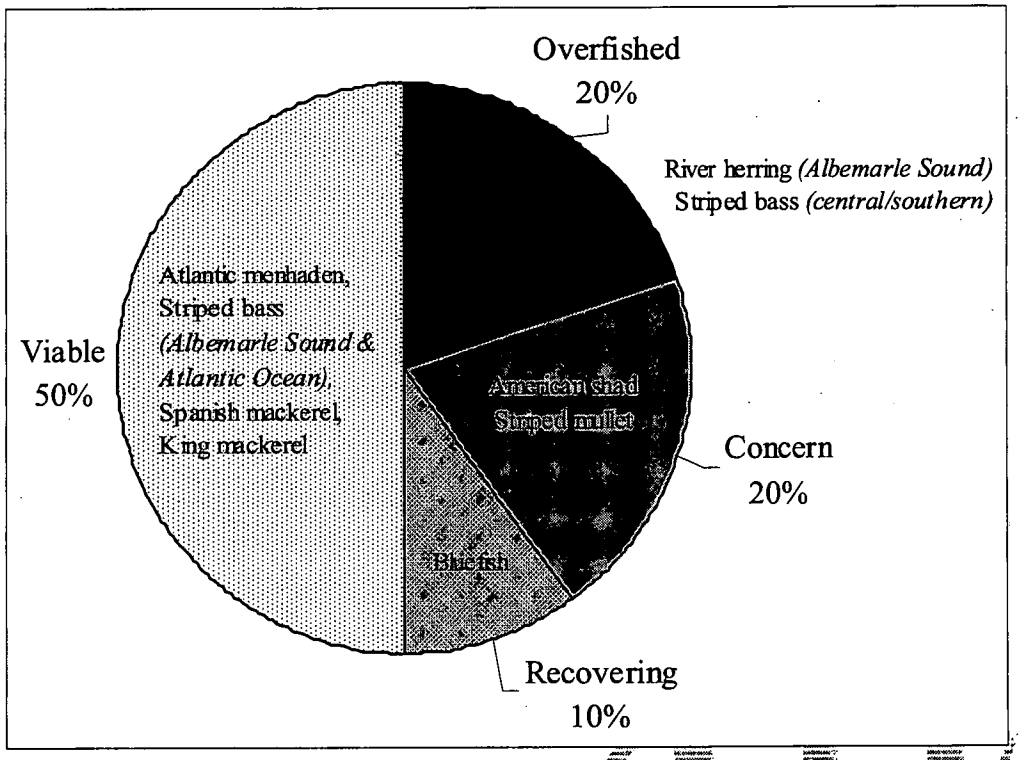

Figure 2.4. Percent of pelagic fish stocks classified as Overfished, Concern, Recovering, or Viable in the 2003 DMF Stock Status Report.

DMF Fishery-independent surveys

DMF conducts several monitoring programs to obtain information on the status of fish species. These programs include the estuarine trawl survey, the Pamlico Sound survey, and the juvenile anadromous survey. The estuarine trawl survey is conducted during May and June at 105 core stations in primary nursery areas. The Pamlico Sound survey samples in June and September at 50-52 random grid locations in Pamlico Sound, Pamlico River and Neuse River. The juvenile anadromous survey, from June to October in western and central Albemarle Sound, includes trawl sampling for juvenile striped bass and seine sampling at 11 core stations for juvenile herring and 19 for striped bass. These surveys collectively provide information on the abundance and diversity of juvenile finfish in North Carolina's estuaries. Juvenile abundance indices (JAIs) are calculated as a standardized measure of catch per unit effort.

Figure 2.5 shows a sharp and consistent decline in blueback herring and a concurrent decline in the commercial catch of river herring beginning around 1986. River herring stocks in the Albemarle Sound Management Area are now considered Overfished and represent a collapsed fishery. The DMF River Herring FMP addressed habitat and water quality issues associated with these species (alewife and blueback herring). Striped bass (Figure 2.6), in contrast to the river herring, indicate a stock that was Overfished during the early 1970s, but is now rapidly recovering as a result of improved management. As a result, both the juvenile abundance index and the commercial catch are increasing. It is important to note that quotas and other fishery management restrictions are limiting the annual commercial landings for both fisheries.

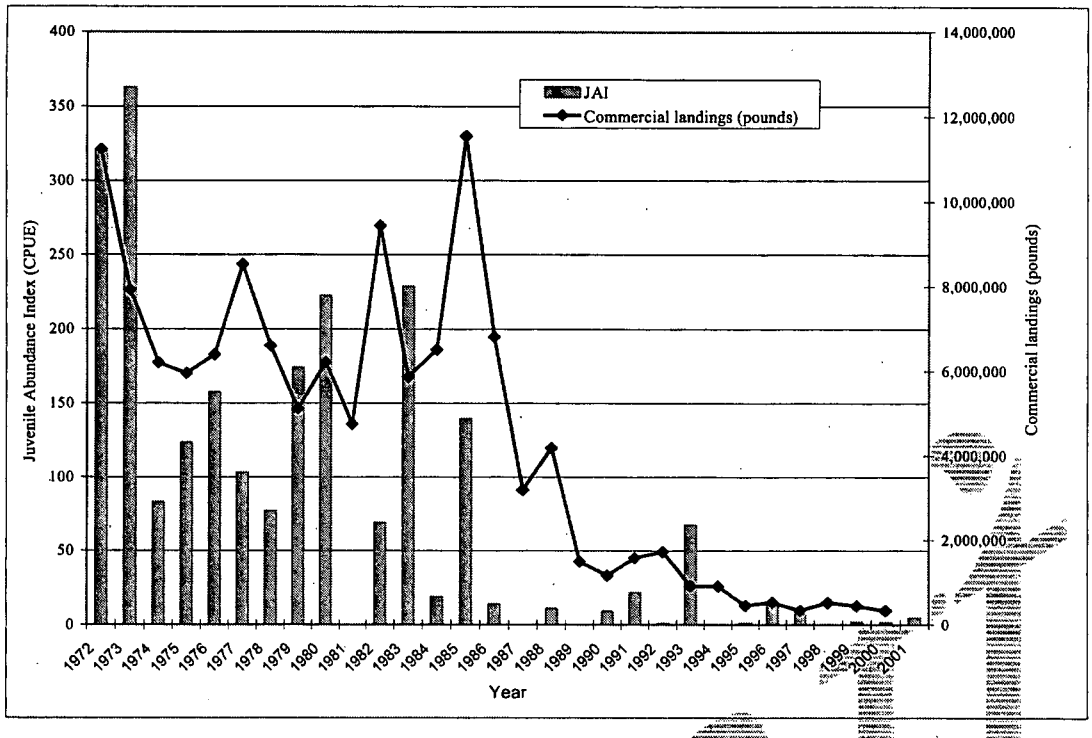

Figure 2.5. Annual North Carolina Division of Marine Fisheries juvenile abundance indices (seine survey) for blueback herring in the Albemarle Sound Management Area and total commercial landings of river herring (alewife and blueback herring), 1972-2001.

Draft

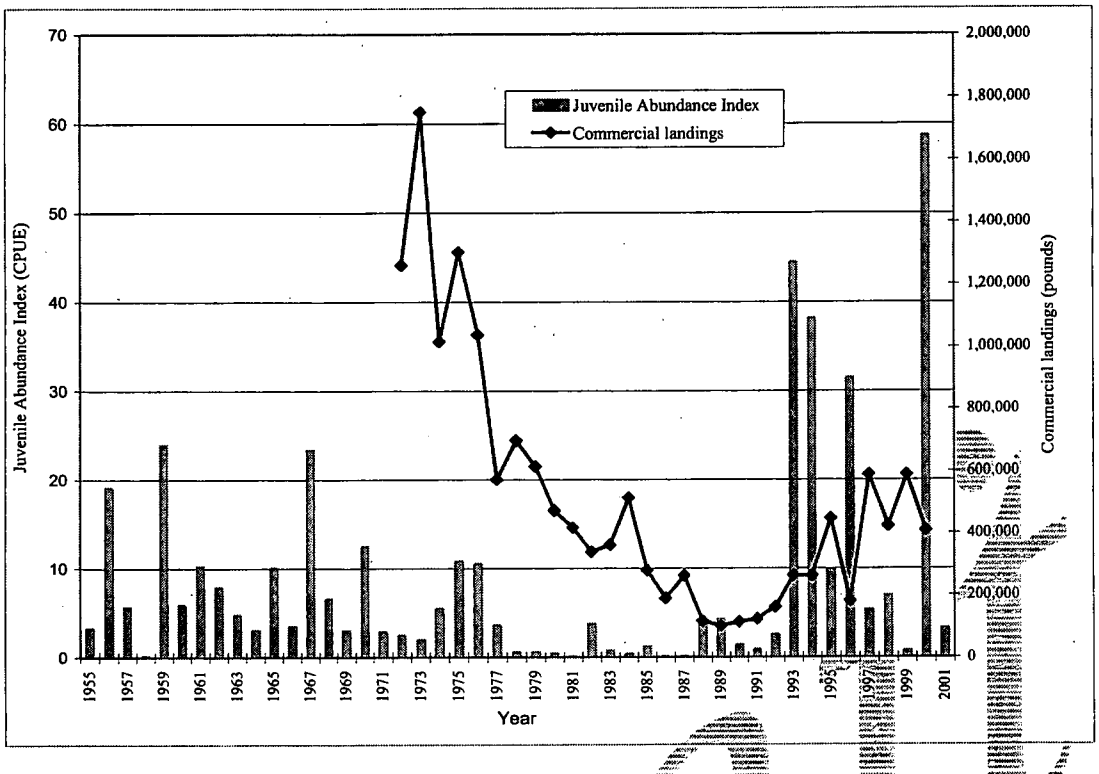

Figure 2.6. Annual DMF juvenile abundance indices of striped bass in the Albemarle Sound Management Area (1972-2001) and total commercial landings of striped bass (1972-2000).

In summary, only half of the predominantly pelagic stocks listed in Table 2.5 are considered viable or recovering stocks. Of the stocks that have a status of Concern or Overfished, the majority are anadromous. Of those anadromous species, river herring (alewife and blueback herring) are the most threatened. For river herring, the suspected causes of stock reductions were both overfishing and degradation of water quality and quantity (DMF 2000c). The only estuarine species of concern was striped mullet. However, potential overfishing (not habitat degradation) is responsible for their concern status (R. Wong, DMF, pers. com. 2002). Juvenile abundance indices of common estuarine species do not indicate clear trends of increasing or decreasing abundance, except for pinfish, which had a large increase in the past few years. However, more apparent trends may be found analyzing data at the watershed or waterbody level (reserved for Management Unit plans).[5]

2.4. THREATS AND MANAGEMENT NEEDS

Human activities can negatively impact fish communities by altering naturally occurring water quality or flow conditions. Hydrological modifications—such as dam and culvert construction; surface water withdrawal; channelization; channel modification; streambank modification; and shoreline erosion—can obstruct fish passage or affect flow and quality of the water column. Pollutant loading from point or nonpoint sources affects the quality of the water column. Drainage projects and point source discharges can also affect the natural distribution and movement of water.

Excessive inputs of nutrients, bacteria, sediment, or toxins, from point or nonpoint sources alike, can lead to visible signs of habitat degradation, including algal blooms, hypoxia, and fish kills. Likewise,

[5] Trends in the condition of the water column will be discussed in the Threats Section.

evidence of the diminished capacity and relative quality of fishery resources is indicated by increased disease incidence, decreased recruitment, lowered reproductive success, or reduced abundance of fish and invertebrates. Threats are organized and discussed in this section by hydrological modifications, water quality degradation, introduced species, and other threats.

The susceptibility of individual fish or invertebrates to threats in the water column will vary by species, lifestage, location, diet, residency, tolerance to change, and the cumulative impact from exposure to multiple stressors. The condition of the water column can affect all other coastal fish habitats. Therefore, identification and evaluation of threats to the water column will aid in protecting coastal fish habitats.

Hydrological Modifications

The ability of various lifestages of fish species to move unobstructed through the aquatic system is a critical component of a healthy water column habitat. Physical structures not only obstruct fish passage but can also alter water flow. The natural flow patterns (volume and timing) of rivers or streams are important mechanisms for maintaining adequate oxygen, salinity, and temperature levels and for dissipating wastes throughout the watershed, including the downstream estuary (DMF 2003b). Unobstructed passage and natural flow patterns are crucial to anadromous species, since they travel great distances and their migration patterns are closely linked to flow conditions. Adult anadromous fish migrating upstream to spawning grounds are generally attracted to higher flows that typically occur in North Carolina rivers in late winter and early spring.[6] Flow pattern alterations, through surface water withdrawal, reservoir storage, or drainage/discharge, affect habitat conditions for anadromous and estuarine fish. Construction of dams, reservoirs, road fill, culverts, bridges, and shoreline stabilization structures can alter flow characteristics or obstruct fish passage. In addition, ground water withdrawals and channelization can alter natural flow patterns.

draft

Flow regulation

Dams/impoundments

Dams have been constructed throughout N.C. to provide flood control, hydropower generation, water supply, irrigation, navigation, recreation, fish and wildlife ponds, debris and sediment control, and fire protection (DLR, unpub. data). The location of dams is shown in Map 2.10. The majority of dams in North Carolina occur in the upstream portions of estuaries, rivers, and streams. In the coastal plain, dams are most abundant in the upper reaches of the Cape Fear, Neuse, Tar-Pamlico, Roanoke, and Chowan rivers (Table 2.17). These structures primarily impact striped bass, river herring, sturgeon, and shad, migrating upstream to spawn, and the catadromous American eel migrating downstream to spawn. These species often migrate hundreds of miles to reach their traditional spawning sites in rivers, streams, and swamps. Eggs and larvae are less likely to survive if passage to their historical spawning areas is obstructed by dams or other alterations (Moser and Terra 1999). The level of impact on spawning and recruitment depends on the location of the dam, spawning grounds, and species requirements. Large dams located in the main stem of coastal rivers primarily impact striped bass, shortnose sturgeon, and Atlantic sturgeon, which spawn in these areas far upstream. Small millpond dams located along tributaries and narrow streams are more problematic for blueback herring and alewife (river herring), which spawn in the shallow upper reaches of streams or swamp waters. Movements of estuarine-dependent pelagic species, such as menhaden, and coastal pelagics, such as Spanish mackerel, are generally not impeded by dams, although water quality and flow characteristics can be affected in ways that impact them.

[6] Refer to Ecological Role and Function Section for more on the importance of flow in anadromous fish spawning.

Table 2.17. Partial or total obstructions in the water column by Management Unit. *(Source: North Carolina DOT – culverts; North Carolina DWR – dams)*

Management unit	Dams	Pipe culverts	Reinforced Concrete Box Culverts
Cape Fear	1160	324	340
Neuse	596	154	219
Roanoke	445	101	78
Tar-Pamlico	241	83	124

Pamlico	1	5	2
Albemarle	0	27	16
Total	**2473**	**761**	**811**

Recently efforts have been made to restore spawning habitat for anadromous species by removing dams that are no longer necessary. In 1997, the Quaker Neck Dam on the Neuse River near Goldsboro was removed, making an additional 74 miles of historic spawning habitat available upstream to the Milburnie Dam near Raleigh. Similarly, the Rains Mill Dam on the Little River in Johnston County was removed in 1999, opening an additional 49 miles of spawning grounds for anadromous species. After dam removal, striped bass spawned further upstream and juvenile American shad used the entire river downstream of the fall line as a nursery area (Hightower and Jackson 2000). Nationwide, about 40 dams have been removed since 1999, and an additional 63 dams in 15 different states are scheduled for removal in 2002. One of these removals is located in a coastal North Carolina drainage, a tributary of Marks Creek in the Neuse River basin (Map 2.10). *This is a positive trend for fish habitat that should be continued.* It is estimated that 30% of the dams in the United States are no longer needed and are more costly to renovate and repair than to remove. Removal has demonstrated almost immediate positive benefits for migratory species (Hightower and Jackson 2000).

Where obstructions cannot be removed, fish passages can be constructed that allow fish to maneuver upstream. In the Chesapeake Bay region, several different types of fish passages are utilized (<http://www.chesapeakebay.net>, 2003). The Denil fishway, which is commonly used in Chesapeake Bay, consists of a series of sloped channels that allow the fish to swim over the dam or obstruction. Wooden baffles are placed at regular intervals within the channels to slow the velocity of the water. There are resting pools between each section of the fishway to conserve the energy of the migrating fish. The necessary slope and length of the fishway is determined by the swimming ability of the predominant species at the site. A fish lift or fish elevator is generally only used at very large obstructions. In this design, a flow of water guides the fish into a large hopper, which then raises the fish over the dam. At the top of the dam, the fish can be released into the river.

In the Cape Fear River, locking procedures were modified and a fishway was installed in 1997 to improve passage of anadromous fish (refer to Appendix H). The U.S. Army Corps of Engineers (COE) has proposed constructing an artificial bypass channel around the lowermost dam (Lock and Dam # 1). The bypass will allow about 10% of the river flow to travel around the dam in a meandering channel that approximates a natural stream (COE 2002). It is not recommended that the dam itself be removed because saltwater intrusion would likely result, impacting the City of Wilmington's water supply. This stream restoration project should greatly benefit habitat conditions for Atlantic and shortnose sturgeon, American shad, striped bass, American eel, blueback herring and hickory shad stocks (COE 2002). Following the construction of the bypass channel, it is hoped that Lock and Dam #2 and 3 can be

removed. *Restoration efforts through removal or modification of dam structures that impede migration of anadromous fish should remain a high priority to continue in North Carolina, focusing on the lowermost structures in rivers or streams, and advancing upstream. In particular, the Cape Fear system (i.e., Lock and Dam #1) should be a high priority, since striped bass, shortnose sturgeon, and Atlantic sturgeon have not recovered.*[7]

Water withdrawals

Water is withdrawn from surface and ground waters for multiple purposes (Table 2.18). Surface water is withdrawn for industrial uses (such as cooling water for nuclear and fossil fuel power plants), municipal water supply, crop irrigation, and other uses. Thermoelectric power generation accounts for the greatest amount of surface water withdrawals. Excluding thermoelectric use, non-agricultural industrial use accounts for the largest source of water withdrawal from both public water supply and self-supplied surface water. Domestic use is responsible for the second largest amount of water withdrawn. Public water supply systems withdraw primarily surface water (633 mgd) and a lesser amount of ground water (135 mgd).

Table 2.18. Most recent estimate of statewide water use compiled by the USGS in 1995, by type of use, in millions of gallons per day (mgd). *(Source: DWR 2001).*

Type of use	Self-supplied surface water	Self-supplied ground water	Public water supply (PWS)	Total
Domestic	0	172	332	504
Commercial	0.3	7.3	138	146
Industrial	308	61	193	562
Mining	4.3	11.7		16
Irrigation	181	57		238
Livestock	207	90		297
Thermoelectric	7,417	0.1	0.4	7,417
PWS losses	-	-	105	105
Total	8118	399	769	9,286

Most surface water withdrawals for power plants or water supply are located in fresh water and associated with a dam or reservoir. Although increasing numbers of potable water intakes are being located in the mainstem of coastal plain rivers (e.g., Neuse, Tar). In some large rivers, such as the Cape Fear, there is a considerable amount of water directly withdrawn from the river for industrial use. The quantity of water removed can be large enough to significantly affect river flow patterns below the intake. The impact of the withdrawal may be offset if treated wastewater or cooling water is discharged back into the same river system. Most cooling water is returned in close proximity to its source, reducing the effect on overall water quantity (DWR 2001). Interbasin transfers could result in large permanent flow reductions (DMF 2003b). Hydropower operations impact water flow conditions for anadromous species by severely altering natural discharge patterns over a short time period. For example, flows on the Roanoke River can increase from 2,000 cfs to up to 18,500 cfs within a few hours, causing rapid change in water depth and temperature, and can quickly affect water levels in adjacent floodplain forest (DMF 2003b). Such drastic changes in flow and temperature can have a major effect on spawning and egg development of anadromous species.

Surface water withdrawal for municipal uses will likely become a major issue for future water conservation. Within the North Carolina portion of the Roanoke River basin, where over half of the total water use is currently derived from surface water, estimated water demand in 43 public water systems is projected to increase 55% by 2020 (DWQ 2001c). Similarly, overall demand for water from public

[7] Refer to Soft bottom section for more information on sturgeon.

sources is forecasted to grow 55%, 70%, and 73% by 2020 for the Tar-Pamlico, Neuse, and Cape Fear River basins, respectively, where surface water presently serves as the primary water supply (DWR 2001). At a minimum, public education is needed to encourage greater voluntary re-use and recycling of water within communities.

The amount of water withdrawn from surface and ground water is tracked through water withdrawal registrations. The Registration of Water Withdrawals and Transfers law (G.S.143-215.22H) requires users who withdraw predetermined amounts of ground and surface water in North Carolina to register annually with the Division of Water Resources (if non-agricultural) or with the Department of Agriculture and Consumer Services (if agricultural) (Table 2.19). Agricultural activities include those "directly related or incidental to the production of crops, fruits, vegetables, ornamental and flowering plants, dairy products, livestock, poultry, and other agricultural products" (G.S.143-215.22H). Because persons or entities who fall below the required use designations are exempt from registration, data obtained from Water Withdrawal Registrations represent minimum estimates of the total water usage.

Table 2.19. Surface and groundwater volumes requiring user registration inside and outside of Central Coastal Plain Capacity Use Area (CCPCUA), North Carolina.

User type	Gallons of water per day (gpd)	
	Inside CCPCUA	Outside CCPCUA
Non-agricultural	> 10,000	≥ 100,000
Agricultural	> 10,000	> 1,000,000

Within the coastal-draining river basins, surface water intakes are permitted in four river basins –Cape Fear, Roanoke, Tar-Pamlico, and Neuse (Table 2.20). The maximum permitted volume of water withdrawal ranges from 73 to 184 million gallons per day (mgd) in the Tar-Pamlico and Neuse, but is more than three times greater in the Cape Fear. The Cape Fear has 27 permitted intakes with a combined maximum flow of 406 mgd. However, these numbers exclude public water supply systems and hydropower facilities. Including public water supply intakes and hydropower facilities, there are at least 33 surface water intakes in the Cape Fear River basin (DWQ, unpub. data; Map 2.11). The North Carolina portion of the Roanoke River and entire Neuse River basin have a similar amount of maximum permitted volume of water withdrawal. Municipal water withdrawals are the largest threat to instream flow in the Cape Fear River. Some of the larger municipalities that receive water from these water intakes include Cary, Apex, Wake County, Fayetteville, and Wilmington. In the Roanoke, withdrawal for power plant use accounts for the majority of the water volume removed. Water withdrawals in the Tar-Pamlico and Neuse river basins are for a mixture of industrial and municipal water supplies. *More research is needed to assess the impact of water withdrawals on water column habitat and fish populations in the affected river basins.*

Table 2.20. Number of surface water intakes and maximum permitted volume of water that can be withdrawn daily (millions of gallons per day) for municipal surface water intake systems in CHPP MUs. *(Source: DWR 2001 and DMF 2003b)*

CHPP MU	Year of data	Number of surface water intakes	Maximum surface water flow (mgd)
Cape Fear	1997	27	405.90
Roanoke (North Carolina portion)	2000	26	147.08 [1]
Neuse	1997	11	183.70
Tar-Pamlico	1997	6	73.30

[1] This figure excludes public water systems and power generating facilities.

Withdrawal of groundwater from wells can also reduce river flows by reducing subsurface flow into

adjacent rivers (Bair 1995; DMF 2003b). Removal of shallow groundwater can be particularly detrimental during low flow periods when subsurface flow is more critical to maintaining baseflow levels. Of the 50 inches of total precipitation per year in this area, it is estimated that approximately 22% enters streams through ground-water seepage, 2% seeps into large rivers and sounds, 10% becomes surface runoff, 66% evaporates, and only 2% percolates into confined aquifers (J. Bales, USGS, pers. com., 2001). These statistics emphasize the significance of ground water seepage in maintaining base flow in streams and the slow process of replenishing aquifers. Eastern North Carolina is experiencing a decline in the quantity of ground water. Between 1989 and 1998 in the Black Creek Aquifer, 10-year reductions in groundwater levels ranged between 3 ft in Greene County and 45 ft in Onslow County. Groundwater levels declined 27 ft decline in Craven County and 22 ft in Beaufort County (J. Bales, USGS, pers. com., 2001). *Assessments of groundwater water supplies in coastal counties should be made to determine what the environmental consequences will be if the increase in water withdrawals continues.*

Effective August 01, 2001, the Environmental Management Commission (EMC) designated 15 coastal counties as the Central Coastal Plain Capacity Use Area (CCPCUA)—Beaufort, Carteret, Craven, Duplin, Edgecombe, Greene, Jones, Lenoir, Martin, Onslow, Pamlico, Pitt, Washington, Wayne, and Wilson—and composed corresponding rules "to protect the long-term productivity of aquifers within the designated area [CCPCUA] and to allow the use of ground water for beneficial uses at rates which do not exceed the recharge rate of the aquifers within the designated area" (15A NCAC 2E .0501). Specifically, to promote the sustainable use of groundwater, "adverse impacts" to existing aquifers are to be avoided or minimized. Examples of adverse impacts include dewatering (i.e., "when aquifer water levels are depressed below the top of a confined aquifer or water table declines adversely affect the resource"), saltwater encroachment, and land subsidence or sinkhole development (15A NCAC 2E .0502). Farming- and non-farming-related users of surface water and groundwater within this area must register if they withdraw greater than 10,000 gpd (Table 2.19). Furthermore, in CCPCUA counties, any user of 100,000 gpd or more of groundwater is required to apply for and obtain a withdrawal permit. Quarterly reporting of groundwater withdrawals and monitoring of groundwater levels are then mandatory requirements for permitted users.

Rules also require reductions in withdrawals from the Peedee, Black Creek, Upper Cape Fear and Lower Cape Fear aquifers, and are being implemented over a 16-year period. One implication is that the demand for high quality surface waters will gradually increase through time. However, permits are not currently required for surface water usage within the CCPCUA. In addition, "intermittent" users are exempted from the groundwater reduction requirements; "intermittent" is defined as "persons who withdraw ground water less than 60 days per calendar year; or who withdraw less than 15 million gallons of ground water in a calendar year; or aquaculture operations licensed under the authority of G.S. 106-761 using water for the initial filling of ponds or refilling of ponds no more frequently than every five years" (15A NCAC 2E .0507). Although several coastal counties (e.g., Hyde, Tyrrell, Currituck, Brunswick, New Hanover) and adjacent aquifers (e.g., Castle Hayne) are omitted from the designated area, the CCPCUA provides a potential foundation for comprehensive, regional conservation of aquifers.

Impingement and entrainment

Cooling water intake systems can cause mortality of fish and other aquatic life by pulling organisms into cooling water systems (entrainment) or trapping them on parts of the cooling water intake structure (impingement). Cooling water intake structures transport surface waters to the intake pump where the force of the water passing through the structure can cause the impingement of organisms. The organisms then suffocate because the water current prevents opening of their gill covers, or die from starvation, exhaustion, or descaling (ASMFC 2002). Fish impinged for a short period can survive or experience delayed mortality from the stress. Protected species, such as shortnose sturgeon, sea turtles, or manatees have also been trapped against or within intake structures. Usually only small organisms, including early life stages of fish and invertebrates, can pass through the mesh screens. The early life stages of fish are particularly vulnerable to damage because their soft tissues offer little protection against thermal or

mechanical stress (EPA 2002). Once entrained, organisms can be subjected to physical, thermal, and toxicity stresses. Studies have shown that very large numbers of fish larvae can be entrained through a power plant and that mortality is high, but varies by species and life stage. Entrainment survival studies found that mortality rates ranged from 2% for naked goby larvae to 97% for bay anchovy (ASMFC 2002). The primary concern of cooling water intake structures is the cumulative impact of multiple facilities on fish populations (ASMFC 2002). For example, in the Delaware Bay estuary, which has four power plant facilities, it was estimated that an average of 14.3 million fish/year were impinged and more than 616 million fish/year were entrained (EPA 2002).

The ASMFC recently formed a Power Plant Panel to conduct a coastwide assessment of the cumulative impact of power plant impingement and entrainment. The results of this workgroup will provide a method for estimating mortality rates based on loss estimates and power plant data. Also, EPA is developing national standards under section 316(b) of the Clean Water Act for cooling water intake structures to ensure that the location, design, construction and water capacity reflect the best technology available to minimize adverse environmental impacts. Standards have already been developed for Phase 1 (new facilities), while Phase II standards for existing electric generating plants using large amounts of cooling water (>50 mgd) are under development. Phase III standards for existing plants that use smaller amounts of water will be developed last. There are 70 surface water intakes for water withdrawals in North Carolina. There are a particularly large number of intakes in the Cape Fear and Roanoke rivers (Table 2.20). In the lower Cape Fear River, a study at the Brunswick Steam Electric Plant found that the combined use of fish diversion structures, fine mesh screens, a fish return system, and flow minimization reduced the number of impinged or entrained larvae and fish by 40–70% (Thompson 2000). The study concluded that the plant operation did not have a significant adverse effect on the fisheries of the Cape Fear Estuary. *Until standards are implemented and effective exclusive technology is available, withdrawals should be reduced as much as possible during and following spawning season in areas known to be used by eggs, larvae and early juveniles. This would include DMF designated PNAs and anadromous fish spawning and nursery areas that are currently being mapped by DMF staff.*

Status and trends in flow regulation

Of the North Carolina coastal river basins, flows are regulated through a combination of dams, reservoirs, and water withdrawals within the Chowan, Roanoke, Tar-Pamlico, Neuse, and Cape Fear river systems. Flows in the Pasquotank, New, White Oak, and Northeast Cape Fear are generally unregulated. All of these rivers historically supported striped bass and other anadromous fish populations (DMF 2003b). Alteration of natural flow patterns by operation of reservoirs and dams can negatively impact fish species. Water releases in the Roanoke River adversely affect flow conditions needed for some anadromous fish species and lower dissolved oxygen levels (Fay et al. 1983a, d; USFWS, unpub. letter 2001). Among other factors, low oxygen levels have been implicated in the decline of the Albemarle/Roanoke River stock of striped bass as well as in fish kill events (USFWS 1992). Status and trends in flow regulation (DMF 2003b) are detailed in Appendix H.

Efforts should continue to remove or modify the lowermost dams in the Cape Fear, Neuse, Tar-Pamlico, and Chowan rivers, in order to increase spawning habitat available to anadromous fish species. *Additionally, new dam construction should be avoided whenever possible or designed and sited to minimize impacts to anadromous fish use and to maintain appropriate flow conditions. Flow alterations that may significantly change the temporal and spatial features of inflow and circulation that are required for successful spawning of anadromous fish should be prohibited. A process that fully evaluates cumulative impacts from water withdrawals and other hydrological modifications should be developed and implemented.* Several other options concerning flow regulation listed in the Striped Bass FMP, which should be implemented (DMF 2003b):

- For free flowing rivers, work with water resources authorities in North Carolina and/or Virginia and South Carolina, as appropriate, to secure commitments for preservation of the unaltered flow regimes.

- For rivers which are presently dammed to such a degree that flow patterns depart significantly from a free flowing condition, require establishment of appropriate flow regimes for striped bass and other anadromous fish spawning and nursery areas, and work with the appropriate regulatory agencies to secure commitments for preservation of such a regime.
- Require water allocation for riverine fish habitat as part of the local water supply planning process and future water allocation processes.

Road fill and culverts

Road construction over rivers, streams, or wetlands often involves blockage of a portion of the original stream. Bridges are the preferred method of crossing over water and wetlands, since they disturb wetlands and obstruct water flow the least. However, bridges can narrow water passages (due to fill placed at the stream edge to support the structure), cause localized erosion, or alter current velocities. Culverts are a common, yet less expensive, alternative to bridges in small water bodies. Depending on the type of culvert and its location, water passages can be partially obstructed. Pipe and box culverts vary in dimensions, but are generally low and narrow passages that reduce light levels in the culverts and constrict water flow. Other concerns are the effects of increased current velocity, erosion around the pipe entrance, vibrations from road traffic, and improper placement of the pipe at height above the natural streambed (Mudre et al. 1985; Clay 1995). Any of these factors may prevent fish from entering the culverts and prevent migration to traditional spawning grounds. However, culvert designs have been improved to minimize impacts from current velocity and erosion (Moser and Terra 1999).

The effect of reduced light from culverts and bridges on river herring migration behavior was examined in a study conducted in tributaries of Albemarle Sound, and Neuse, Pamlico, and Cape Fear rivers in 1999 (Moser and Terra 1999). Results showed that river herring preferred to migrate through areas with some ambient lighting during the day, but required only a low amount of light – at least 1.4% of ambient light. Where lighting was less than 1.4% ambient conditions, avoidance was observed. Light measurements in the center of the structures were below this threshold in six ft diameter corrugated metal pipes and 6' by 6' box culverts. Sufficient light was available in 12 ft diameter pipes and bridges more than one meter above the water surface. Light was marginally adequate in bridges less than one meter above the water surface. Light penetrated approximately ten feet inside the 6 ft diameter culverts. Since the average length of the 6 ft diameter pipes was 54 ft, approximately 30 feet in the center of the pipes was dark. Although culverts may reduce the number of herring passing upstream of the structures, some fish did successfully pass through culverts at night and, in some cases, under low light conditions (<1%) during the day. Culverts and bridge locations in North Carolina are shown in Map 2.12. Table 2.17 summarizes the number of dams and culverts in each CHPP MU.

In 1999, three hurricanes hit North Carolina within a four-week period, causing major flooding in the eastern part of the state. Although the hurricanes were natural events, the magnitude and duration of flooding and the associated human disaster were exacerbated by the extensive man-made modifications to the natural drainage systems (Riggs 2000). Modifications to the drainage system include dams, road blockages, stream channelization, dikes, ditching and draining of secondary floodplains and upland pocosins, and increased impervious surface (reduced infiltration and increased polluted runoff) resulting from urban development (Riggs 2000). In the aftermath of this flooding, it became apparent that culverts also severely slowed drainage pathways.

Because of the observed hydrological impacts, the MFC supported replacement of all temporary stream crossing structures with structures that were "herring friendly", including bridge piling structures and properly designed and situated box culverts. In 2001, an interagency team including staff from DOT, DENR, COE, and other state and federal agencies began meeting to discuss such changes, as well as other changes in permit processing improvements and mitigation. From this effort, the team established an Ecosystem Enhancement Program (EEP), which will manage watershed-based compensatory mitigation

for the entire state, incorporating ongoing monitoring and management of mitigation projects, as well as emphasis on resource preservation and restoration of wetlands, streams, and other resources impacted by DOT projects. *Through this process, additional focus on restoring stream flow and fish habitat through the replacement of culverts with bridges should be accelerated. Funding should be allocated for replacing filled channels and streams with "fish friendly" culverts or bridges and upgrading existing culverts to "fish friendly" structures, prioritizing structures that are known to impede anadromous fish migration to spawning grounds or have been found to be particularly problematic to the natural hydrology of a system.*

Transportation-related activities (e.g., road fill, diversion) have been responsible for altering thousands of stream acres per year, based on 401 water quality certifications (DWQ, unpub. data). The impacts have frequently occurred in headwater streams, which are known to assimilate many times more nitrogen than larger streams within a watershed (Peterson et al. 2001). Using a subset of 426 project records from 1987 to 2003, transportation-related activities accounted for 42% of the total stream distance impacted. The majority of impacts during the 2001/2002 fiscal year were to intermittent (often headwater) streams (WRP 2002). In previous years, the majority of impacts were in piedmont and large urban areas (WRP 2001). Some of the authorized stream impacts were offset by stream restoration. The net distance of stream impacted from 1999 to 2002 was 126,091 linear feet, a very small percentage of total stream mileage in coastal river basins. However, the total stream distance impacted does not address the concentration of impacted stream reaches, which could lead to localized degradation of water column functions for anadromous fish.

Channelization and ditching

Channelization is the deepening and straightening of a natural stream, or dredging of a new channel, to improve drainage of adjacent lands or for navigation (North Carolina Sea Grant 1997). These activities can affect the slope, depth, width and roughness of the channel, disturbing the dynamic equilibrium of the stream. Channelized streams take up less land and allow adjacent wetlands to be drained and used for agriculture. Channelized streams are often deeper, with more extreme flows, less woody debris and less variable depth than natural streams. These changes primarily affect smaller species and early life stages that use shallow stream margins, since these areas are reduced with channelization. Water in low slope areas can back up in the channel and overflow the banks during large storm events, allowing some continued function of the floodplain (North Carolina Sea Grant 1997).

Channelization has a number of impacts on the coastal aquatic environment. By removing the meanders of the channel and increasing the slope of the shoreline, water velocities in the altered stream are higher. Higher water velocity results in higher erosional-energy and downcutting of the channel, which in turn prevents further meandering. Erosion often results in an increased sediment load in the channelized stream, which will be deposited downstream. In many channelized streams in the middle and lower coastal plain, storm flows are confined primarily to the main channel rather than passing through wetlands and achieving some filtration of pollutants and other wetland functions. In addition, the natural woody vegetation along the sides of the stream is often removed in the process of channelization. Consequently, loading and movement of sediment and other nonpoint source pollutants are often greater in channelized sections than natural streams, which can have negative impacts on water quality and therefore fish habitat (EPA 2001; White 1996). Nutrients, particularly nitrogen and phosphorus, may increase with channelization. Elevated water velocities can also deter or prevent movement of adult and juvenile fish. A study in the Tar River, for example, found that high water velocities in channelized sections of a stream prevented the entrance of adult and juvenile herring into those areas (DMF 2000c; Frankensteen 1976). Also, early larval river herring in the tributaries of the Chowan system were found to be highly associated with the stream edge and waters with minimum flow (O'Rear 1983). In addition, the spoil banks created by disposal of spoil along the shoreline prevent fish from accessing sloughs, floodplain forest, and other adjacent wetlands (DMF 2000c).

Due to their typically short length and relatively lower habitat quality, channelized streams generally support fewer fishery resources than unaltered, meandering streams. Several studies have found that the size, number, and species diversity of fish in channelized streams are reduced and the fisheries associated with them are less productive than those associated with unchannelized reaches of streams (Tarplee et al. 1971; Schoof 1980; Hawkins 1980). Pate and Jones (1981) compared nursery areas that were altered and unaltered by channelization and found that brown shrimp, spot, croaker, southern flounder, and blue crab were more abundant in nursery habitats with no man-made drainage. They attributed this to the unstable salinity conditions that occurred in areas adjacent to channelized systems following moderate to heavy rainfall (>1 inch/24 hr). Channelized streams have also been found to have less suitable spawning habitat and reduced recruitment success for anadromous species (Sholar 1975). These observed declines in habitat quality are attributed to the changes in flow characteristics, water quality, and decrease in structural complexity.

The amount of in-stream vegetation, woody debris and streamside vegetation is generally reduced in channelized streams (DMF 2000c). Removal of in-stream vegetation and woody debris reduces the substrate for fertilized herring eggs, the protective cover for adult and juvenile fish, and habitat for invertebrates (DMF 2000c). Macroinvertebrate species richness, biomass and production are higher on snags and debris than any other habitat in Coastal Plain streams. In the Satilla River, Georgia, a typical Coastal Plain river, 90% of the food items and 60% of prey biomass of most large fish are invertebrates dwelling on these habitats (Smock and Gilinsky 1992). Removal of large woody debris also contributes to accelerating water velocity. Streamside vegetation is important as a source of in-stream woody debris and shade from the overhanging tree canopy, which helps maintain cooler water temperatures. Clearing of the woody vegetation along the riparian shoreline will therefore result in less woody debris in the water, higher water temperatures, and reduced bank stability.[8] *De-snagging of woody debris from streams for navigation or other purposes should be minimized to enhance water column habitat value.*

The formation of new channels involves ditching or the creation of vegetated swales (very wide ditches with sloping banks) to control stormwater runoff for urban development, agriculture, or forestry. The ditches often connect and drain into headwaters, altering the natural hydrology of downstream systems. Ditches can degrade water quality and alter flow conditions by moving stormwater from uplands more rapidly, causing pulses of stormwater with lower salinity or high levels of sediment, nutrients, toxic chemicals, or bacteria (Heath 1975; Jones and Sholar 1981). In a Florida estuary, Serafy et al. (1997) found differences in fish community structure from stable salinity habitats versus those adjacent to freshwater canals. The difference was attributed to the varying ability of species to adapt to salinity changes. For example, pinfish were more tolerant of salinity change than spotted seatrout. In tidal creeks with extensive channelization and ditching, the volume and speed of stormwater runoff increased considerably during storm events, and resulted in elevated fecal coliform levels (White et al. 2000).

In coastal North Carolina, channelization activities include drainage and flood control projects, clearing and de-snagging of freshwater streams, creation of ditches and canals for drainage of low-lying agricultural land, dredging of new navigation channels, maintenance dredging of existing channels, road construction, and residential development (DEHNR 1995b). Most streams in eastern North Carolina have been channelized to some extent (North Carolina Sea Grant 1997). North Carolina has a long history of stream channelization and drainage. Many of the original canals and waterways in North Carolina, dating to the 1770s, were constructed for inland navigation. In the late 1800s, a large portion of state-owned wetlands was sold for large-scale timber harvesting. This led to a need for additional drainage required for mechanized harvesting. In addition, a large network of canals and ditches was constructed to drain wetlands for agriculture, following World War II, primarily on the Albemarle-Pamlico Peninsula. These drained wetlands have become the most productive cropland in North Carolina, accounting for more than 50% of the total annual crop yield (North Carolina Sea Grant 1997). Much of the land around the

[8] Refer to the Wetlands section of this plan for more information on the impacts of channelization to wetlands.

Albemarle-Pamlico estuary is drained and must remain drained to accommodate existing agriculture and forestry. It is estimated that over two million acres of land have been drained and developed for agriculture and forestry along the North Carolina coast. Within every square mile of agricultural land in coastal North Carolina there are estimated to be more than 20 miles of field ditches, collector canals, and main canals (Heath 1975 and Daniel 1978). Many of the roads on the Albemarle-Pamlico Peninsula were constructed on top of spoil piles between canals to prevent flooding. Ditching of wetlands or uplands is also common in other areas of the coast for flood control and drainage. In many urbanized coastal areas, ditches are typically constructed along neighborhood streets, which to nearby coastal waters.

There are many policies currently in place that restrict new channelization. Stream channelization for flood control and drainage of low-lying farmland and mosquito ditching are no longer common practices. "Swampbuster" provisions of the 1985 Farm Bill prohibited the practice of draining wetlands for conversion to cropland. However, some stream channelization projects for agricultural drainage are still maintained in North Carolina by drainage districts (DEHNR 1995a). There have been no new drainage projects since the mid-1970s (Chicod Creek, Pitt and Beaufort counties, Tar-Pamlico MU). *New channelization projects should not be constructed unless found to be absolutely necessary and designed to minimize or adequately mitigate any negative habitat and water quality impacts.* Although channelization for flood control and drainage has greatly decreased, the existing alterations continue to alter flow and salinity patterns. *Dechannelization of streams, particularly in areas historically utilized as fish nurseries, implementation of alternative drainage control practices, and acceleration of innovative BMP development are needed where feasible. Increased funding and educational outreach to farmers and other landowners are also needed for such projects.* These habitat enhancements could improve fish productivity and recruitment success.

Ditching for stormwater control and draining of wetlands are regulated by the state. In 1999, DWQ adopted a wetland draining policy to ensure that required wetland conditions are maintained (<http://h2o.enr.state.nc.us/ncwetlands/ditch.html>, 1999). In addition, inspections were made of previously ditched wetlands to determine if the ditching was conducted in a manner that violated wetland standards. Of the 65 ditching projects inspected, there were 24 Notices of Violation issued (SCC 1999). Turbidity was the standard most frequently violated by ditching. Where violations occurred, property owners were required to restore the natural hydrology through the filling of the ditches. Approximately 50% of the ditched wetlands are to be restored, 22% are likely not to be restored, and the status of the remainder is undetermined (J. Steenhuis, DWQ, pers. com., 2002). Fishermen in Brunswick County reported to DMF staff that, for two or three years following wetland ditching, there was a distinct absence of blue crabs and other finfish in a creek receiving newly ditched runoff (D. Beresoff, commercial fisherman, pers. com., 2003). Dissolved oxygen levels were found to be very low (DMF, unpub. data). After several years, however, fishery landings appeared to return to levels similar to nearby unaffected areas. This may be because some of the ditches upstream of the creek had been in violation and DWQ ordered these to be restored. Other ditches, although not appearing to violate water quality standards, continue to transport stormwater into coastal waters. *Additional monitoring, paid for by the party responsible for the ditching, is needed to better assess impacts where extensive areas of wetlands were drained. More DWQ staff are needed to inspect for compliance with the wetland draining policy.*

Dredging (channels, boat basins)

Dredging for channel maintenance, marina basin construction, shipping channels, ports, or mining for sand or minerals has similar impacts to the water column as channelization. Dredged channels associated with ports are generally much deeper and more extensive than other navigational channels. Elevated turbidity during and after dredging can affect juvenile fish by clogging their gills, which can result in mortality or reduced feeding or movement (Ross and Lancaster 1996). Dredged channels act as sediment traps, accumulating fine silt and pollutants (DEHNR 1990). This fine material can easily be resuspended by boat wakes, wind, or periodic channel maintenance. Chemicals, metals, nutrients, and organic matter stored in the sediment can then re-enter the water column, causing short-term increases in turbidity, algal

blooms, and biological oxygen demand (BOD). *The cumulative impact of these episodic increases in turbidity, algal blooms, and biological oxygen demand on fish stocks, including growth, survival, and feeding success of early life stages and visual feeders, is unknown and should be assessed.*

The conversion from shallow to deep water areas can also result in a proportional loss of nursery habitat for some estuarine-dependent species (Rozas 1992). Habitat alteration from dredging may have been responsible for some major reductions noted in brown shrimp (-88%), blue crab (-75%), Atlantic croaker (-45%), and spot (-19%) following dredging for a marina site on Pierces Creek (Neuse River) (DMF, unpub. data). Recruitment of invertebrate larvae, growth of filter feeding invertebrates, and visual foraging for prey by adult and juvenile fish are also affected by turbidity from dredging (Reilly and Bellis 1983; Hackney et al. 1996; Peterson et al. 2000a).

Lindquist and Manning (2001) quantified the effect of dredging on visual foraging by Florida pompano. When pompano were exposed to turbidity levels of roughly 80 NTUs, predation on coquina clams and mole crabs decreased by 40.5% and 30%, respectively. This represents turbidity levels that are conservatively similar to what was generated by a nearby disposal project and substantially above natural turbidity conditions (340 NTUs near the discharge point; 59 NTUs 70 m downstream; 6 – 30 NTUs at upstream control site). Dredging and resulting turbidity plumes occurring near inlets during mid to late winter and spring could potentially impact larval fish survival alongshore and through inlets into estuaries due to gill clogging or exposure to low DO levels, toxic heavy metal concentrations, and sulfides (J. Miller, NCSU, pers. com., 2001). Dredging of borrow areas may also result in anoxic or low-oxygen conditions within the excavated areas, degrading the area for fish use and possibly causing mortality of invertebrates (Lalancette 1984). *Dredging and beach nourishment activities must be managed in a manner that minimizes impacts to the water column and other habitats. Completion and implementation of a DENR Beach Management Plan that is consistent with the CHPP would provide guidelines that minimize environmental impacts.*

There are two major commercial shipping ports in North Carolina which have extensive areas of dredged channels and basins. The ports are located in Morehead City and Wilmington. The dredged areas are as deep as 38 – 44 ft. Navigational channels were dredged through most major coastal water bodies in North Carolina by the COE in the 1930s to create the Intracoastal Waterway. The locations of ports and major navigational channels are shown in Map 2.13a-c. The primary dredging activities still occurring within North Carolina's coastal waters are maintenance or improvement dredging of existing navigation channels (DEHNR 1995a).

Dredging in estuarine waters is prohibited from March to November in order to avoid disturbing the bottom in nursery areas when juvenile fish are present. Navigational dredging in inlets by the COE is allowed at any time of the year and is not subject to any mandatory dredging moratoriums unless sea turtle take quotas are exceeded. Industry-owned hopper dredges working in the Wilmington and Morehead City port areas and Oregon Inlet have a voluntary dredge window of January 1 – May 31, to minimize taking of turtles (T. Wilder, COE, pers. com., 2003; NMFS 1997). Side-cast dredging can be conducted at any time of the year (COE 1979). Seven inlets are maintenance dredged on a regular basis with a hopper or pipeline dredge. Many of the remaining inlets are dredged periodically as needed with a side-cast dredge. Dredged material from the side-cast dredge is moved from the channel's center to its edge (T. Wilder, COE, pers. com., 2003). Material collected from a pipeline dredge is pumped onto a nearby downdrift beach. This method can move larger volumes of sediment, but often cannot be used in the inlets due to rough seas or shallow water depth. Excavated material from a hopper dredge is disposed of in the surf zone along the 10-foot depth contour, or transported to an offshore dredge disposal site. This is the most frequently used method in North Carolina's inlets.

Dredging impacts fish populations by engulfing fish larvae primarily near the bottom. The allowed dredging period during winter corresponds to when ocean-spawned larvae are passing through inlets and

the lower estuaries toward their nursery areas in the upper estuary. However, this time period was selected to minimize sea turtle impacts, DO impacts, and to avoid ecosystem function impacts during the active growing season. While turbidity from dredging may protect young fish from visual predators, it may also expose them to heavy metals and other pollutants stored in the sediment[9] (refer to Toxic chemical subsection later in this section).

Mining

In coastal North Carolina, there are surface, open pit mines for sand/gravel, crushed stone, and phosphate. Sand/gravel and crushed stone mines occur generally in upland areas, although some may be located in or adjacent to wetlands (M. Street, DMF, pers. com., 2004). Sand/gravel mines are the most common mine in coastal North Carolina (<www.geology.enr.state.nc.us/ Permitted%20Mines%201999-2000/permitte.htm>, June 2004). In CAMA counties during 2001, there were 249 permits for sand/gravel mining, seven permits for crushed stone mining, and two permits for phosphate mining. The two phosphate mining permits, totaling 15,952 acres, were for PCS Phosphate in Beaufort County. In the past, whole creeks were lost to PCS Phosphate's mining activities. The open pits created by coastal mines fill with groundwater that is often pumped out into ditches and rivers (G. Cooper, DWR, pers. com., 2004). The discharge can contain sediment, nutrients, and heavy metals. However, the discharge of pollutants from mines is undoubtedly small compared to stormwater runoff from farms and urban/developing areas. Among coastal mining operations, PCS Phosphate is the largest discharger. Before 1992, PCS Phosphate was discharging 50-60 million gallons/day of phosphate-rich water into Pamlico Sound (Steel 1991). This nutrient-rich effluent was contributing to eutrophication of the Pamlico River. Today, PCS Phosphate uses a water recycling process that has greatly reduced discharge of nutrients.

The focus of mining activities in coastal waters has been mostly limited to sand acquisition for beach nourishment projects. Dredge material from inlet and other navigation projects is also used for beach protection purposes.[10] In addition, there are currently two areas in North Carolina ocean waters that are used as sand sources (borrow areas), one off Carolina Beach and the other off Bogue Banks. Another borrow area has been proposed off Bodie Island. Impacts of dredging to intertidal beach, soft bottom, and hard bottom are discussed in those sections of the plan.

Log salvage operations are a form of mining involving removal of submerged logs from lakes, rivers, or estuaries. In North Carolina, log salvage operations have been permitted in the Cape Fear, Roanoke, and Perquimans rivers. The major concern with the removal of logs is the procedure's effect on water quality. The Log Salvage Policy Development Team was created by DENR, in response to growing interest by commercial operations in this industry, to assess the potential impacts of this activity and to establish the most appropriate permit process. Their habitat and water quality concerns included (DENR 2000c):

- Increased turbidity and sediment loading could negatively impact the integrity of anadromous fish spawning and nursery areas, SAV, and waters classified as NSW.
- Resuspension of sediments with toxic materials released into the water column could impact fishery resources or their prey.
- Where located above the surface, removal of woody debris and structure used by anadromous and resident fish reduces its habitat value.

Log salvage operations may also need to be restricted from anadromous fish nursery areas, due to the primarily freshwater distribution of those species. The Log Salvage Policy Development Team made recommendations to minimize adverse impacts to aquatic systems. Recommendations affecting water quality include:

[9] Refer to: Corridor function subsection under Ecological Role and Function section; Light and water clarity subsection of Ecological Role and Function section; Toxic chemical subsection later in this section.

[10] Refer to the Soft Bottom section for more detailed discussion of beach nourishment.

- Preparing a programmatic EIS for log salvage operations as a comprehensive approach to provide sufficient information to decide permit approval.
- The Secretary of DENR should adopt BMPs and operation conditions developed by the Team until appropriate policies can be implemented.
- Address impacts on a regional scale in North Carolina, with consideration of the variety of aquatic habitats and living resources.
- Log salvaging should be prohibited in areas with SAV or shell bottom. A seasonal moratorium should be established regionally, to avoid salvage operations during peak fish spawning and juvenile recruitment periods.

Jetties

Jetties can potentially interfere with the passage of larvae and early juveniles from offshore spawning grounds into estuarine nursery areas. Approximately 60 species of larval fish and 34 species of juvenile and adult fish have been documented moving through Beaufort Inlet, Ocracoke Inlet, and Oregon Inlet in the winter and an even greater number of species during the summer months (Peters et al. 1995; Hettler and Barker 1993). Successful transport of larvae from fish spawning on the continental shelf through the inlet occurred within a narrow zone parallel to the shoreline and was highly dependent on along-shore transport processes (Blanton et al. 1999; Churchill et al. 1999; Hare et al. 1999). Obstacles such as jetties adjacent to inlets block the natural passage for larvae into inlets and reduce recruitment success (Blanton et al. 1999; Kapolnai et al. 1996; Churchill et al. 1997). Impacts may be greatest in coastal areas like the Outer Banks, where there are few inlets. Offshore spawning, estuarine-dependent species that might be impacted by jetties include many of North Carolina's most important commercial and recreational fish species such as menhaden, spot, Atlantic croaker, shrimp, gag, black sea bass, and flounders.

Most of North Carolina's inlets do not have jetties. There is a long dual jetty system at Masonboro Inlet and single groins at Beaufort and Oregon inlets (Map 2.14). There is also a jetty at Cape Lookout, although it is not immediately adjacent to Barden's Inlet. The Oregon Inlet project proposed to lengthen the existing groin and add a similar jetty on the other side of the inlet. Miller (1992) and Settle (NMFS, unpub. data), in reviewing the potential impacts of a dual jetty system at Oregon Inlet, estimated that successful passage of winter-spawned, estuarine-dependent larvae through Oregon Inlet could be reduced 60-100%.

The jetty construction's effect on fisheries has been discussed and reviewed at length by the scientific community in association with the proposed construction of a dual jetty system at Oregon Inlet (COE 1999). In the latest EIS (COE 1999), The Fish and Wildlife Coordination Act Report concluded that the Oregon Inlet project should not be constructed because of, among other concerns, the impact of jetties on larval fish passage. Although there are conflicting opinions on the magnitude of fisheries impacts of a dual jetty system at Oregon Inlet, there is valid concern that construction of the structures would prevent some portion of ocean spawned larvae from reaching estuarine nursery areas (COE 1999). Construction or lengthening of jetties, particularly where inlets occur infrequently along the coast (for example, Oregon Inlet), could lower successful fish recruitment and fishery productivity (Blanton et al. 1999; Churchill et al. 1997; Kapolnai et al. 1996). *Construction of new or expanded jetties or groins along North Carolina's ocean shoreline should not be allowed until field research has been completed to assess the impact of jetties on successful larval passage through inlets into estuaries, particularly in Pamlico Sound where inlets are limited. Environmental outreach to the public, particularly commercial and recreational fishermen, regarding the effect of inlet stabilization on coastal fish habitat is needed to educate the public on this issue and gain support for maintaining natural barrier island processes.*

Shoreline stabilization

Shoreline stabilization using vertical structures, such as seawalls on the ocean shoreline or bulkheads on the estuarine shoreline, can impact the condition of the nearshore water column in several ways. During

construction, soil disturbance may increase turbidity in adjacent waters and reduce light penetration. This can reduce primary productivity, interfere with respiration and feeding of fish and invertebrates, release heavy metals that may occur in the sediment, and smother aquatic vegetation (Watts 1987). Although shoreline stabilization structures may retain eroding sediments from land, the continual scouring of sediment at the base and downdrift of the structure may resuspend sediment, chronically elevating turbidity adjacent to bulkheads (Watts 1987; Clark 1974). The scouring action at the toe of seawalls and bulkheads results in deepening of the adjacent water, reducing or eliminating shallow water habitat preferred by many juvenile fish (SAFMC 1998; DMF 2000a). *The state should enforce the prohibition of hardened structures on the oceanfront. In addition, existing seawalls and hardened structures on the oceanfront should be removed if they are more than 50% damaged and if removal will be beneficial to coastal fish habitat. Where shoreline stabilization structures such as rock revetments, sills, or bulkheads are allowed adjacent to fringing wetlands, permit conditions should require openings in the structures to allow adequate fish ingress and egress and water circulation. To minimize impacts to the water column and its functions, CRC estuarine shoreline stabilization regulations should be modified.*[11]

Water Quality Degradation

In addition to altering erosion and sedimentation dynamics, human activities can and often do change the chemistry of the water. Changes in chemistry causing degradation of water quality can originate from defined points such as industrial or wastewater discharges (point sources) or from land-use patterns contributing pollutants by sheet flow or through drainage features (nonpoint sources). The primary point source pollutants are oxygen-consuming wastes, nutrients, and toxins, including chlorine, ammonia, and metals. A National Pollutant Discharge Elimination System (NPDES) permit is needed for all point source discharges. Most NPDES discharges treated municipal or industrial wastewater (Map 2.15).

Nonpoint source pollution is pollution that enters waters through diffuse sources with no defined point of entry. Nonpoint pollutants are generally carried into waters by rainfall, runoff, snowmelt, or air deposition. Stormwater drains and swales also carry polluted stormwater into coastal waters, but are technically considered nonpoint sources. Unlike point sources, nonpoint pollutant loading varies with weather patterns and land disturbance. The North Carolina Coastal Nonpoint Source Program categorizes nonpoint pollution by land activities:

- Hydromodification (drainage ditches),
- Agriculture,
- Forestry,
- Marinas, and
- Urbanization.

Each activity associated with these categories can contribute multiple pollutants. Sediment and nutrients are most often associated with nonpoint source pollution, but other pollutants, including fecal coliform bacteria, toxic chemicals such as heavy metals, oil, and pesticides, may be carried into coastal waters as well (DWQ 2000a). The biological impacts and human sources associated with these pollutants are discussed below, as well as status and trends.

Land cover and water quality

Land cover and water quality within a watershed are closely linked (EPA 1992). Table 2.21 below provides a brief overview of some river basin characteristics (population, land cover), and major water quality problems that were noted in the summaries of the river basin plans. When considering the overall population of each river basin, the Neuse and Cape Fear river basins are the most densely populated, and the Chowan and Pasquotank are the least populated. The distribution of population is not even; there are

[11] Refer to the Wetlands and Soft Bottom Sections for more information on the impacts of shoreline stabilization to those coastal fish habitats and the status of this activity.

watersheds. So while impervious cover is overestimated by the NRI classifications, percent imperviousness is underestimated for the areas that most influence coastal waters. *These numbers indicate that water quality problems associated with development and excessive impervious cover will continue to worsen unless improved land-based strategies that reduce nonpoint source pollution are voluntarily utilized at a local level. Such strategies could include providing incentives for low impact development, improved BMPs and other techniques.*

[1]This land cover classification represents a close approximation of percent impervious cover, but could somewhat overestimate in some areas.

USGS HUs in **bold** were >10% urban/built-up and rural transportation in 1997.
USGS HUs in *italics* are predicted to reach >10% by 2012.

Any activities which alter vegetated riparian buffers can affect water quality. Logging operations, particularly clear-cutting and stream crossing, can also cause considerable hydrological and water quality change to freshwater and brackish streams. A study of Goshen Swamp, a Coastal Plain blackwater stream that was clearcut, found that the clearcut caused violations of ambient N.C. water quality standards for turbidity, chlorophyll *a*, fecal coliform bacteria and DO compared with a control stream (Ensign and Mallin 2001). Despite a 10 m (33 ft) buffer left along the streambank, these violations occurred over a two-year period following the clearcut. The buffer was less than the state BMP recommending a 50 ft minimum buffer. Desbonnet et al. (1994) summarized studies documenting the different benefits of various buffer widths. Scientific literature suggests that minimum buffers between 26 ft (8m) and 75 ft (23 m) wide are needed to protect water quality and riparian habitat from logging impacts (Desbonnet et al. 1994; Ensign and Mallin 2001). In the Neuse, Tar-Pamlico, and Catawba river basins, there is a mandatory buffer of 50 ft from mean high water, with exemptions for managed forests and selective harvesting of high value trees. *Mandatory 50 ft buffer zones should be required along all streams*

draining to coastal fish habitat in North Carolina.

All forestry-related land-disturbing activities, regardless of river basin, must be conducted in accordance with forestry practice guidelines related to water quality to qualify for exemption from Sedimentation Pollution Control Laws. A streamside management zone must be established and maintained wide enough to confine visible sediment resulting from accelerated erosion. The guidelines included a recommended buffer of 50 ft, which is not always followed (Ensign and Mallin 2001). *Therefore, increased funding and incentives are needed to encourage compliance with forest practice guidelines. In addition, converted riparian wetland areas should be restored or enhanced to increase filtration and retention of upland runoff.*

Nutrients

Nutrients are chemical compounds or elements that are needed for growth of living organisms and are beneficial in appropriate amounts. Nitrogen and phosphorus are the major plant nutrients responsible for regulating growth of phytoplankton, algae, and other marine plants (DeAngelis et al. 1989). Most North Carolina estuaries already have relatively high nitrogen levels; adding nitrogen to those systems may degrade water quality. Freshwater systems tend to be limited in ability to receive added phosphorus without adverse effects (North Carolina Sea Grant 1997). While a certain level of these nutrients is needed to support aquatic life, an overabundance of nutrients due to human activities may have a negative impact on the environment. Nutrient overenrichment and the resultant problems are called eutrophication.

Nutrient enrichment is a problem to coastal fish habitat for several reasons. Elevated nutrients can trigger a rapid increase in phytoplankton, resulting in algal blooms. Blooms tend to occur when water temperatures are warmer, water flow is slower, and where mixing of the water column is reduced due to salinity or temperature gradients. In freshwater areas, blue-green algae are usually associated with blooms, and they have lower nutritional value to aquatic life than other types of algae. In estuarine and marine waters, dinoflagellates are usually responsible for algal blooms (North Carolina Sea Grant 1997). With nutrient enrichment, there is a shift in the dominant plant community from slower growing SAV and perennial macroalgae to faster growing phytoplankton, microphytobenthos, and ephemeral macroalgae (Duarte 1995). Another direct effect of eutrophication on estuaries is the increased biological oxygen demand resulting from the sedimentation and resuspension of accumulating organic matter (Gray et al. 2002). Nutrient enrichment and algal blooms are therefore often accompanied by oxygen depletion.

Elevated levels of phytoplankton in the water column reduce water clarity. Reduced water clarity reduces successful feeding by some visually orienting fish (Peterson et al. 2000a). When light penetration is sufficiently reduced, survival and growth of submerged aquatic vegetation can be impacted. Other indirect effects of nutrient enrichment include changes in the biomass, community structure, growth and reproduction rates of invertebrates, and change in the organic carbon inputs and biogeochemistry of the sediments (Cloern 2001). Algal blooms are also aesthetically undesirable to the public; the unpleasant odor and degraded visual appearance of the water's surface (green scum) discourage swimming, boating and fishing.

Some dinoflagellate species release toxic chemicals into the water column. Neurotoxins from algae, released into the water upon death, harm fish and shellfish by affecting their nervous systems and paralyzing their respiratory systems (Tyler 1989). Organisms such as clams, oysters, and some benthic fish can die of suffocation because of nervous system paralysis. Humans that eat contaminated seafood can also experience neurological symptoms (Tyler 1989). These blooms are sometimes referred to as "red tide" because the dinoflagellates can make the water appear red in color. In 1987, there was a large red tide event in North Carolina waters attributed to Gulf water intrusion into nearshore waters, carrying the toxic dinoflagellate *Karenia brevis* (Tyler 1989). This event resulted in contamination of shellfish and coastal fish consumption advisories for an extensive time period, significantly impacting several North

Carolina fisheries. Globally, the incidence and frequency of red tides has increased in recent decades. Eutrophication is considered to be partially responsible for this increase, as well as transport of algal bloom species through ship ballast water (Hallegraeff 1998).

Another toxic dinoflagellate, *Pfiesteria piscicida*, may have contributed to a number of large fish kills in North Carolina estuarine waters since the late 1980s. *Pfiesteria* produces a toxin that could be responsible for large fish kills (Burkholder et al. 1992a). Since then a second species, *Pfiesteria shumwayii,* has been discovered, and fish kills in Chesapeake Bay have been attributed to these organisms (Glasgow et al. 2001). Other studies suggest that the mechanism of fish mortality in *Pfiesteria* is actually micropredation, rather than toxin release (Vogelbein et al. 2002). There is not full scientific consensus on the human effects of *Pfiesteria* exposure (Gratten et al. 1999; Rubin et al. 2001). Burkholder et al. (1995), Burkholder and Glasgow (1997), and Glasgow et al. (2001) provide data on numerous estuarine fish kill events, including number of fish killed, concentrations of *Pfiesteria*, DO and nutrients present at the site, whether toxicity of *Pfiesteria* was confirmed by subsequent laboratory bioassays, presence of lesions on fish, presence of other potentially toxic algal species, and water temperature. It is important to note that, since *Pfiesteria* abundance is stimulated by nutrient loading into estuaries, the occurrence of *Pfiesteria* is not independent of other eutrophication effects (Burkholder and Glasgow 1997; Glasgow et al. 2001). Low DO has also been documented to cause large fish kills in areas where *Pfiesteria* was also present (Paerl et al. 1998) (refer to oxygen depletion section). Conditions such as bacterial, viral, parasitic, and fungal infections, ammonia toxicity, chemical pollutants, sudden changes in temperature or salinity, and bycatch from commercial fishing are also possible causes of fish kills.

Fish sampling was initiated in 1998 by DWQ, DMF and NCSU to determine the occurrence of and species impacted by *Pfiesteria* and ulcerative mycosis (UM) in three estuarine systems with a history of large fish kills – Neuse, Tar-Pamlico, and New rivers. Lesions were found to be most common on menhaden and occurred on fish captured in areas with low to moderate salinities within the Pamlico River (Noga et al. 1989). Similar signs of disease were found on fish representing 19 species, including southern flounder, striped bass, weakfish, spot, croaker, silver perch, bluefish, pinfish, gizzard shad, and hogchoker. Both benthic and pelagic species were affected. The observed incidence of disease ranged from 10.0% in the Pungo River to 33.0% in the middle Pamlico River; 18.2% in the lower Neuse to 44.2% in the upper Neuse River; and 3.9% in the upper to 10.2% in the middle of the New River (DMF 2000b). Disease incidence was highest in May in all river systems, followed by the months of November and December. The presence of low DO, a stratified water column, increased phytoplankton, and active fertilizer application and pesticide spraying on farmland in the spring may have increased stress levels in fish, leading to increased disease in May (DMF 2000b). While skin ulcers were the most frequent abnormality observed in fish, fin erosion, abnormal pigmentation, tumors, skeletal abnormalities, and operculum damage were also reported.

Sources of nutrient enrichment

Nutrients enter surface waters from point and nonpoint sources. While point sources are highly regulated and effluent quality has improved over the years, nonpoint sources have only recently been recognized as significant contributors to eutrophication and are more difficult to control because of the diffuse pathways into coastal waters. Primary point sources of nutrients are (DWQ 2000b):

- Municipal wastewater and stormwater discharges; and
- Industrial wastewater discharges.

There are a total of 901 NPDES discharges into coastal waters covered by the CHPP management area (Map 2.15). Of these, 74 are major and 75 are minor municipal NPDES discharges. There are also 143 major and 609 minor non-municipal NPDES discharges within the CHPP. Non-municipal discharges include those from water treatment plants, fish houses, reverse-osmosis plants, phosphate mines and industrial activities. Nutrients also enter water from spills, plant failures, or inadequate treatment. In

2002, a relatively dry year, there were 2,047 spills reported from government or private waste collection systems that reached surface waters, totaling 56.9 million gallons (DWQ, unpub. data). In wet years, the totals are generally larger. The Albemarle-Pamlico National Estuarine Program's Status and Trends Report (Steel 1991) listed point sources as the cause for degradation in 12% of evaluated streams. *Loading of nutrients into coastal waters from mechanical failures, spills, and inadequate treatment must be reduced. This will require additional funding to upgrade plants and infrastructure. Increased inspections of sewage treatment facilities, collection infrastructure, land disposal sites, and onsite wastewater treatment facilities is necessary to identify and prioritize sites needing upgrades.*

There are numerous nonpoint sources of nutrients. Agriculture is believed to be the single largest contributor of nutrients in watersheds of the southeastern United States (SAFMC 1998). The primary land use activities that contribute nonpoint delivery of nitrogen and phosphorus to North Carolina waters are (Spruill et al. 1998; USDA 1997; Steel 1991):

- Agricultural fertilizer from crop production;
- Livestock waste from concentrated animal operations;
- Urban development (lawns, pets, sewage, golf courses); and
- Air emissions from industry and vehicles.

Nutrients enter coastal waters through stormwater runoff, air deposition, groundwater discharge and rainfall. In the Albemarle-Pamlico system, nonpoint sources are estimated to account for the majority of the nutrient loading (94% for nitrogen and 84% for phosphorus) (Spruill et al. 1998). Precipitation accounts for about 20-30% of the total nitrogen inputs from nonpoint sources in the Albemarle-Pamlico basin (Spruill et al. 1998). Sources of nitrogen in the air and rain are car exhaust, industrial emissions, and waste from animal operations (USGS 2003). Within the coastal river basins, 44.7% of the impaired miles of freshwater streams in 1998-1999 were related to agricultural runoff (cropland and animal operations) (Table 2.23).

In a study of the Albemarle-Pamlico estuarine system, the four major river basins (Chowan, Roanoke, Tar-Pamlico, and Neuse) contained elevated concentrations of nitrogen and phosphorus (Spruill et al. 1998). Crop agriculture and animal operations were estimated to contribute approximately 50% of the nitrogen load and 75% of the phosphorus load. The effect of crop agriculture on water quality depends on the specific crops grown, weather, and the use of Best Management Practices (BMPs) (Steel 1991). The acreage of cultivated crop agriculture in coastal North Carolina has remained about the same or declined since the early 1980s. In addition, use of effective BMPs is increasing primarily due to availability of funds and technical assistance from multiple programs administered through the U.S. Department of Agriculture, Natural Resources Conservation Service, North Carolina Department of Agriculture and Consumer Services, and North Carolina Division of Soil and Water Conservation (DSW). *However, because of the large percent of nutrients attributed to crop agriculture, aggressive steps should continue to reduce nutrient loading.*

While crop production has declined in North Carolina's coastal plain, animal operations have greatly increased in the past 10-15 years (Table 2.24). The location of current animal operations is shown in Map 2.16. The primary types of animal operations using liquid waste-management systems are swine, cattle, and poultry. Swine operations are the most abundant and poultry the least abundant (Table 2.24). There are a total of 1,999 swine operations, with a design capacity of approximately 7 million animals, in the CHPP management area. The numbers of facilities and swine are greatest and most concentrated in the Cape Fear MU, followed by the Neuse, and Tar-Pamlico. Although relatively uncommon, cattle operations are most abundant in the Cape Fear, and poultry operations are most abundant in the Neuse. The Core/Bogue and Southern Estuaries MUs have a small number of animal operations. Nationally, North Carolina is one of the largest swine and poultry producing states in the U.S., having undergone much growth in those industries in the past decade (Barker and Zublena 1995).

Total steady state live weight is a standardized measure in pounds calculated from number of animals.

The presence of concentrated animal operations on river floodplains has been shown to be a danger to fish survival and habitat suitability (Mallin et al. 2000a; Mallin et al. 2001c). Animal wastes are highly concentrated sources of nutrients, fecal coliform bacteria and other pathogenic microbes, and oxygen-consuming materials (Sobsey 1996; Burkholder et al. 1997; Mallin et al. 1997; Mallin et al. 2000a).

Waste from animal operations is commonly discharged into lagoons, where it undergoes some anaerobic digestion and is then sprayed on fields. Pollutants may be transported into surface waters or groundwater if the lagoon ruptures, leaks or overflows. Pollutants can also enter groundwater beneath sprayfields and move laterally down slope toward streams (Mallin et al. 2000a). Between 1995 and 1999, multiple animal waste lagoon accidents and several hurricanes resulted in breaching, overtopping, and flooding of animal waste into coastal waters (Burkholder et al. 1997; Mallin et al. 1997; Mallin et al. 2000a). Lagoon waste also entered streams via spraying onto fields already saturated from rain (Mallin et al. 2000a; Mallin et al. 2001c). In 1995, the spilling of concentrated animal wastes into coastal waters in the lower Cape Fear and New Rivers resulted in anoxic and hypoxic conditions; high nitrogen and phosphorus concentrations; dense phytoplankton blooms, high bacteria levels, high turbidity, and fish kills (Burkholder et al. 1997; Mallin et al. 1997).

Groundwater can be contaminated through leaking lagoons or leaching of waste applied on sprayfields. Preliminary estimates by DENR indicate 25% of lined facilities may leak, thereby potentially contaminating groundwater. DENR data show that conventional sprayfields seem to be just as problematic as lagoons. Increased levels of nutrients in the air and deposition into coastal waters have been associated with the substantial increase in livestock operations (Paerl and Whitall 1999). Approximately two-thirds of the nitrogen in the swine excretions are emitted to the air due to the design of lagoon and sprayfield systems. According to a DENR study, swine facilities are responsible for an estimated 20% of North Carolina's total atmospheric nitrogen compounds, 53% of which was contributed by eastern North Carolina alone. Those compounds react with other constituents in the air and are deposited on land, vegetation, and water bodies.

The N.C. legislature has taken a number of steps to reduce water quality impacts from animal operations:

- Since 1995, operators at swine facilities with 250 or more animals are required to be trained.
- Beginning in 1996, new and expanding facilities are required to obtain permit.
- In 1997, DWQ was directed to inspect all animal waste management facilities annually.
- A moratorium on new or expanding swine operations was imposed in 1997 and has been extended several times. The moratorium currently extends to 2005.
- DENR was required to develop and adopt economically feasible odor control standards.

In addition, the Clean Water Management Trust Fund (CWMTF) provided funds to the Division of Soil and Water Conservation to buy out hog farms located in floodplains. To date, 14 swine operations have been bought out at cost of $5,737,500. In 2002 the Division of Soil and Water Conservation received a second grant of $6,062,000, which will be used to buy out approximately 11–12 additional operations (D. Williams, DLR, pers. com., 2002). Research on cost-effective alternatives to the lagoon and sprayfield system is underway (D. Ramsey, DWQ, pers. com., 2002). *More funding is needed to buy out or relocate additional animal operations from environmentally sensitive areas. The moratorium should remain in effect until alternative waste treatment is implemented that will reduce pollutant loading to streams and nitrogen release into the air. In addition EMC should phase out use of waste lagoons or reclassify waste lagoon systems from nonpoint to point source discharges, and be permitted accordingly, as recommended in DENR's Neuse River Nutrient Sensitive Waters Management Strategy* (DWQ 1997b).

Other ongoing initiatives to reduce water quality impacts from crop or animal agriculture include the Conservation Reserve Enhancement Program (CREP) and the Farmland Protection Program. CREP targets riparian protection and wetland restoration in river basins designated as Nutrient Sensitive Waters. Objectives include reducing sediment and nutrient impacts through installation of forested riparian buffers, grassed filter strips, wetland restoration BMPs, water control structures, and livestock exclusion. Landowners in the Neuse, Tar-Pamlico, and Chowan river basins and the Jordan Lake watershed are eligible to participate in CREP. The 2002 Farm Bill represents an unprecedented investment in conservation on private lands, committing over $13 billion nationally over a six-year period (USDA 2002). In 2002, The Farmland Protection Program allocated over $2 million to North Carolina and the

Wetlands Reserve Program allocated $5 million. The funding will be used primarily to purchase conservation easements and provide technical and financial assistance to landowners to address wetland, wildlife habitat, soil, water, and other natural resource concerns. *A greater portion of agricultural conservation funds should be allocated to the buy out or relocation of animal operations from sensitive areas, and for the purchase of conservation easements.*

These initiatives offer promise in reducing pollutant inputs from agriculture, but voluntary BMPs for agriculture have not been adequate to protect environmentally sensitive areas such as primary nursery areas (Preyer 1994). *Additional measures to reduce inputs from agriculture should be considered by the CRC, EMC, MFC, and NRCS, such as removing their exclusion of agriculture from CRC and EMC regulations, expansion of funding for BMPs and cost-share programs for nonpoint pollution control.*

In June 2002, the N.C. General Assembly took a major step toward reducing nitrogen and sulfur emissions from power plants by enacting the "Clean Smokestacks" Act. The Air Quality/Electric Utilities Bill (SB 1078) required significant emissions reductions from coal-fired power plants in North Carolina. Under the Act, power plants must reduce their nitrogen oxide emissions 77% by 2009 and sulfur dioxide emissions 73% by 2013. The cuts in both SO_2 and NO_x emissions will improve respiratory conditions for North Carolina residents, as well as reduce acid rain and airborne deposition of nitrogen in coastal waters. Certain technologies used to reduce SO_2 and NO_x also reduce mercury emissions. A statewide mercury advisory currently warns against consumption of four ocean fish species (king mackerel, shark, swordfish, and tilefish) and three freshwater fish species (bowfin, chain pickerel, and largemouth bass) in eastern North Carolina because of high mercury levels. The Act also requires DENR to evaluate issues specifically related to the control of mercury and carbon dioxide emissions and make recommendations on the development of standards and plans to control these emissions.

Automobiles are the largest contributor of air pollution in North Carolina. This is attributed to increasing urban sprawl; members of a more dispersed human population typically drive longer distances per day in vehicles, contributing to increased nitrogen emissions. *The Division of Air Quality and DENR should implement the planned expansion of car inspections as soon as possible. In addition, North Carolina legislators, state agencies, and local governments should adopt coastwide or statewide "Smart Growth" policies to provide incentives and direct growth into more highly developed areas and preserve rural land uses.*

Nutrients are also transported into coastal waters through shoreline erosion processes. A study in the Chesapeake Bay region found that sediments from eroding high bank shorelines were significant sources of nitrogen and phosphorus loading (Ibison et al. 1992). The nutrient loading rates from highly eroding shorelines in the study varied considerably but were higher than that estimated from typical agricultural runoff. Adjacent land use was also a factor in nutrient loading concentrations in eroding sediments. In the Chesapeake study, sediment from active farms had the greatest average total nitrogen and phosphorus loading concentrations (Ibison et al. 1992). A study by UNC-W, in New Hanover County, found that soils under suburban and golf course grasses were highest in phosphorus, followed by soils in wet detention ponds and runoff channels. Soils in undisturbed forests had the least phosphorus associated with them (Mallin et al. 2002a). Their results indicated that fertilizer use was positively correlated with phosphorus levels. Both studies suggest that sites with high sediment loss and intense fertilizer use, such as agricultural land, golf courses, or manicured lawns, have high potential for nutrient contributions to the water column. North Carolina's shorelines should be evaluated to identify potential hot spots of nutrient inputs from eroding shorelines. *Additional education is also needed on proper application of fertilizers to reduce runoff of nutrients into coastal waters, targeting homeowners, golf course owners, and landscape businesses (Mallin and Wheeler 2000).* New Hanover County recently produced a publication entitled "Homeowner's Guide to Lawncare Best Management Practices" that offers information on proper dosages and methods of fertilizer application and other lawn care strategies. *Similar efforts are needed to reach and educate all fertilizer users throughout coastal North Carolina.*

Mallin and Wheeler (2000) studied the effect of golf courses in New Hanover and Brunswick counties on water quality in adjacent water bodies. This study found that ammonium and orthophosphate appeared to be fairly tightly bound to the soils and remained on site during normal base flow conditions. However, nitrate levels in streams leaving golf courses were greater than streams entering the courses. Nitrate levels at some sites were high enough to cause significant increases in phytoplankton biomass and algal blooms in the spring and summer. Nitrate levels varied widely and appeared to be related to stormwater management practices. Waters adjacent to golf courses having vegetated buffer zones, wet detention ponds, and wooded wetland areas had considerably lower nutrient levels than sites without these landscape features and management tools (Mallin and Wheeler 2000). *BMPs, including vegetated buffers, detention ponds, and wetland areas, should be required on all new and existing golf courses draining to coastal waters to help reduce nutrient concentrations.*

Status and trends in nutrient enrichment

Nutrient levels can be measured directly (levels of nitrogen and phosphorus) or indirectly (chlorophyll *a* concentrations). Chlorophyll *a,* a component of most algae, is a commonly used indicator of algal biomass and relative nutrient levels. The North Carolina standard for chlorophyll *a* in lakes, reservoirs, and slow-moving waters not designated as trout waters is 40 µg/l. Concentrations greater than the standard are an indication of a nutrient problem and potential algal bloom. The miles of freshwater streams and acres of estuarine waters that were classified as impaired by chlorophyll *a* for the 1995-1999 time period are shown in Tables 2.25 and 2.26. In terms of measurements, the Neuse River has the most estuarine acres impacted by nutrients, followed by the Tar-Pamlico and White Oak river basins. In the freshwater portion of the river basins, the White Oak had the most stream miles impaired by chlorophyll *a*, followed by the Neuse and Cape Fear river basins. However, this is only one indicator of nutrient enrichment. For example, in the lower Cape Fear River, Mallin et al. (2001c) reported reasonably high nutrient levels in the river channels, but algal blooms rarely occurred. This was attributed to high flushing and reduced water clarity from turbidity and color, which reduced photosynthesis (Mallin et al. 2001c).

[1] Habitat degradation is identified where there is a notable reduction in habitat diversity or change in habitat quality. This term includes sedimentation, bank erosion, channelization, scour, loss of pools or riffles, and loss of woody habitat.

Table 2.26. Estuarine acres rated as impaired in 1998-1999 305(B) report, by river basins and major pollutant causes (DWQ 2000a).

River Basin	Major Causes (Acres)		
	Fecal coliform	Low DO	Chlorophyll *a*
Cape Fear	3,602	5,000	0
Lumber	2,622	0	0
Neuse	3,588	0	28,950
Pasquotank	4,862	1,125	0
Tar-Pamlico	4,825	0	3,455
White Oak	8,936	0	3,005
Total	28,435	6,125	35,410
% PS or NS miles	41	9	51

PS = partially supporting, and NS = not supporting

Another factor which affects chlorophyll *a* concentrations is tidal stage. A study of tidal creeks in New Hanover County found that chlorophyll *a* concentrations were greatest at mid to low tide (Mallin et al. 1999a). The reason for higher nutrient levels at lower tides was primarily attributed to transporting of nutrients from the adjacent marsh and headwater areas. Headwater areas often have the

highest chlorophyll *a* concentrations within a tidal creek (Laws et al. 1994; Mallin et al. 1996; Mallin et al. 1999a). Other studies have also found that falling tides transport algae from upstream to downstream sources (Litaker et al. 1987; 1993).

Based on NAWQA results, nutrient concentrations in the Albemarle-Pamlico basin were high relative to other areas in the country (Spruill et al. 1998). Several stations in the Neuse and Tar-Pamlico systems were among the highest 25–50% of stations sampled in the United States, with the Neuse River having the highest nitrogen and phosphorus yields. The lowest nutrient levels occurred in streams of the predominantly forested Chowan River basin. Permitted point sources (municipal wastewater treatment plants and industrial facilities) of nitrogen and phosphorus account for less than 5 percent of the nutrient source inputs in all basins. However, pollution from these sources enters directly into streams, contributing up to 20 percent of the in-stream nutrient load. Intensive agriculture, wastewater discharges, and urban runoff from Piedmont areas contributed to particularly high concentrations in the Neuse and Tar-Pamlico river basins. A geologic source also contributes to naturally high phosphorus in the Neuse and Tar-Pamlico.

Although nutrient levels were relatively high, the NAWQA study found that nitrogen and phosphorus concentrations in streams had shown a general decline since 1980 in all four basins. The decrease in nutrient levels was thought to be due to improved agricultural practices, the phosphate detergent ban in 1988, and improved water treatment practices. Although nutrient levels declined, they remained high enough in the Tar-Pamlico and Neuse river basins to continue to cause algal blooms. In fact, the authors estimated that a 50% reduction of nitrogen and phosphorus concentrations in the Neuse River and a 30% reduction in the Tar River during summer months were needed to reach levels that will reduce the incidence of nuisance algal blooms and fish kills to more natural levels.

The National Oceanic and Atmospheric Administration's Estuarine Eutrophication Survey assessed the scale and scope of nutrient enrichment and eutrophication in the North Atlantic, South Atlantic and Gulf coasts. The report summarizes conditions in tidal freshwater, mixing, and seawater zones of Albemarle-Pamlico sounds, Pamlico-Pungo rivers, Neuse River, Bogue Sound, New River, and Cape Fear River. Medium or greater concentrations (≥5 ug/l) of chlorophyll *a* occurred in 19 of 21 South Atlantic estuaries, and were most frequent in estuarine mixing zones (66% of the areas sampled). High (>20 ug/l) concentrations were reported periodically in 11 of 21 estuaries. Nuisance and toxic algae events occurred throughout all salinity zones in the South Atlantic but were concentrated in North Carolina estuaries (NOAA 1996). The upper Pamlico River and the Neuse River had increasing chlorophyll *a* concentrations in the mixing zone, while most others showed no trend or a decreasing trend, especially in the tidal freshwater and mixing zones (NOAA 1996). The only systems that did not have a problem with nuisance or toxic algae at that time were Bogue Sound and the Cape Fear River. The remaining systems reported algal blooms at least once during the course of the year. Some of the Albemarle-Pamlico system estuarine waters experienced the most severe problems. Because the Albemarle-Pamlico estuaries are wind driven systems and do not directly drain into ocean waters, tidal flushing is limited and weak. Consequently, nutrients and detrital matter are stored in the sediments, maintaining eutrophic conditions (Luettich et al. 1999).

The Neuse River MODMON research has found that riverine discharge, nutrient loading, and circulation (flushing and stratification) are strongly related and primarily determined by weather patterns. Irregular weather patterns and lack of long-term data complicate trend analysis. In addition, because of the shallow depth of the estuary, the bottom sediments store and release nutrients and carbon that can fuel algal blooms or low-oxygen events, independent of new sources, making it difficult to evaluate the effectiveness of nutrient reductions and management actions (Luettich et al. 1999). Some important findings of the research pertinent to fish habitat include:

- Nitrogen loading has declined since 1999.

- Blooms in the upper system north of New Bern have declined. This is attributed to wastewater treatment plant improvements.

Priority research regarding nutrient enrichment, identified by the MODMON team, include:

- Obtain better information on rates of nutrient exchange, carbon processing and residence time in the estuarine system.
- Improve understanding of the transfer of nutrients and organic matter between primary producers, zooplankton, and benthic invertebrates; and fish to better assess the relationship among water quality, fish habitat and fish productivity.
- Develop a watershed model that tracks the fate and transformation of nitrogen through the watershed from the point of origin (i.e., outfall, stream edge, smoke stack) to the time it enters the estuary. The model should be used with water quality models to improve development and evaluation of management options.

A five-year study (1993-98) on nutrient loading and chlorophyll abundance in the Neuse River estuary by the NCSU Center for Applied Aquatic Ecology indicated a 14% reduction in phosphorus loading to the estuary, but increases in total nitrogen (+16%) and inorganic nitrogen (+38%) (Glasgow and Burkholder 2000). There was also a decrease in chlorophyll *a* concentrations over the period. Since that period and during the drought years 2000-2002, nitrogen loading stabilized but chlorophyll *a* increased by 25%. The authors recommended increased reduction of inorganic nitrogen inputs and co-management of phosphorus due to expanding swine production (285% increase observed from 1990-1999) and human population increase (17% increase observed from 1990-1999) in the watershed.

The Lower Cape Fear River Program (UNC-W) has monitored nutrients and other parameters since 1995. Total nitrogen was higher and more variable during 1996 and 1997 than in 1995, and leveled off between 1998 and 2001. This was thought to be due to flushing of accumulated organic matter from swamp waters into the channels during 1996 and 1997 hurricane seasons, reducing the excess organic nitrogen available during subsequent hurricanes (Mallin et al. 2001c). Total nitrogen loads were somewhat lower in blackwater rivers than in the mainstem Cape Fear River. In 2000-2001, nitrate levels, the main form of inorganic nitrogen in the lower Cape Fear River, were slightly lower than the five-year averages, except at three stations. Sources of high nitrate concentrations were nonpoint agriculture and animal waste drainage, and industrial and municipal wastewater discharges. Total phosphorus concentrations in 2000-2001 in riverine stations and the upper estuary were higher in 2000-2001 than the six-year average, while concentrations in the middle and lower estuary were lower. Like nitrogen, phosphorus was highest at upstream stations, declining in estuarine waters seaward to the ocean. At stations with high total phosphorus, industrial or municipal wastewater discharge was considered the primary source (Mallin et al. 2001c).

The Cape Fear Program's tidal creek monitoring found that nutrient loading was high enough in several of the creeks (Bradley and Hewlett creeks, both in southern estuaries MU) to support small algal blooms periodically. The high nutrient concentrations in Hewletts Creek were largely attributed to two golf courses that drain to the creek. Futch Creek has continued to maintain good water quality in terms of nutrients since the mouth of the channel was dredged in 1995–1996. Futch Creek and Pages Creek have the least development and impervious surfaces in their drainage area compared to the other creeks studied, and the least water quality degradation. *Areas like Futch or Pages Creek, that have relatively good water quality condition and are important nursery and shellfish producing areas, should be a high priority for water quality maintenance and protection through stormwater control BMPs, such as vegetative buffers and impervious surface limits and land conservation. Comprehensive sampling, similar to that done in the Tidal Creeks Program in New Hanover County, is needed for other tidal creeks in Brunswick, Pender and Onslow counties that are highly important nursery and shellfish areas.*

Oxygen depletion and fish kills

Low-oxygen conditions can occur naturally in a system from flushing of swamp waters, which characteristically have low DO, or from stratification of the water column due to wind, temperature, and salinity conditions. However, low-oxygen conditions can also be fueled by nutrients and oxygen-consuming wastes, which result in excessive oxygen demand in the water column or sediment. Algal blooms deplete the water column of DO as respiration from the dense concentrations of plants consumes oxygen at night (DWQ 2000b). Dissolved oxygen can be further depleted as bacteria use oxygen to decompose the algae's organic material. The algal blooms may occur naturally in coastal waters or occur with greater frequency or intensity upon inputs of nutrients. Dissolved oxygen depletion in the water column occurs most often in summer. Warmer water holds less DO and increases microbial decomposition. In addition, warmer water, calm winds, and reduced freshwater inflow in the summer reduce mixing and aeration of water. The stratified bottom layer of water is prevented from receiving oxygenated surface waters and rapidly becomes depleted of oxygen. Shallow water estuaries with less frequent flushing often develop persistent stratification and bottom-water hypoxia that can last for weeks to months (Tenore 1972).

Low-oxygen events frequently occur as a result of increased runoff and organic loading from heavy rainfall. The habitat and fishery impacts of weather events can be either positive or negative. For example, hurricanes can flush out large quantities of organic matter that has accumulated in estuarine systems, temporarily causing low dissolved oxygen, but reducing excessive nutrients that could otherwise fuel eutrophication over many years.

Prolonged periods of hypoxia or anoxia can cause stress or mortality of many aquatic organisms. One of the most visible effects of oxygen depletion is a fish kill event. According to NOAA, the leading cause of fish kill events in 22 coastal states from 1980 – 1989 was low DO (Lowe et al. 1991). Atlantic menhaden and other small schooling fish were noted as the most affected in estuarine waters. In North Carolina, this has also been the case; in 2001 DWQ attributed 34% of the fish kills to low DO and 4% to algal or dinoflagellate blooms. Other reported causes of fish kills included bycatch mortality, extreme temperatures, waste, chemical, and pesticide spills (DWQ 2001b). Although *Pfiesteria*-like cells were identified with some fish kill events, toxic *Pfiesteria* was not reported as a cause in any of the 2001 fish kills (DWQ 2001b). Low oxygen has been identified as a major water quality problem in Chesapeake Bay for blue crabs, and low DO has local impacts on menhaden, bay anchovy, spot, white perch, and striped bass (<http://www.chesapeakebay.net/>, 2003). Although fish can migrate away from hypoxic areas and seek refuge in shallower oxygenated waters, wind-driven circulation can rapidly transport the hypoxic bottom-water into shallow waters, trapping fish and causing large fish kills of estuarine fish (Paerl et al. 1998).

From 1996 to 2000, the annual number of reported fish kill events remained fairly consistent, ranging from 54 to 60 per year, but increased to 77 in 2001 (DWQ 2001b). Coastal river basins account for the majority of these fish kills (Table 2.27). Some of the fish kills in 1996 were associated with Hurricanes Fran and Bertha (L. Henry, DMF, pers. com., 2003). Total fish mortality has varied annually but generally increased, with total mortality ranging from 92,000 in 1997 to over 1.3 million in 2001. July and August are the peak months of fish kill occurrence (DWQ 2001b).

In 2001, fish kills were concentrated in the Neuse (37 fish kill events) and the Tar-Pamlico river basins (23 events). Fish kills in the Neuse River were clustered in the upper sub-basins near Wake County and the lower sub-basins between New Bern and Minnesott Beach. Fish kills in the Tar-Pamlico River were clustered downstream of Washington and around the Pungo River. Map 2.17 shows the location of fish kills within the CHPP MUs from 1999-2001. Although fish kills have been reported in all of the eight coastal river basins between 1996 and 2001, the majority of the fish mortality occurred in the Neuse, Tar-Pamlico, and Cape Fear river basins (DWQ 2001b). Since 1999, the number of fish kill events in the Cape Fear system has declined while the Neuse and Tar-Pamlico systems have increased. In the coastal river basins, fish kills have been least abundant in the Roanoke and Chowan river basins.

Over twenty different fish species were identified in fish kills in 2001 by DWQ (Table 2.28). The suspected causes of the fish kills included low DO, algal blooms, chemical spills, bycatch, and hog lagoon spills, as well as unknown factors. Low DO accounted for 34% of the fish kills, while algal blooms were only reported as a factor in 4% of the events (DWQ 2001b).

In addition to suffocation, fish are impacted by low-oxygen conditions due to an associated increase in sulfide production in bottom sediments. This combination of conditions is lethal to many benthic organisms (Tenore 1972), which can have significant effects on the aquatic food chain (Peterson et al. 2000a; Taylor and Eggleston 2000). Mortality began to occur after species were exposed to 0.5-1.0 mg/l oxygen for five days (90% mortality of blue crabs after exposure for about 3 days), although many species, such as the mud crab *Neopanope sayi*, the serpulid polychaete *Hydroides dianthus*, the polychaete *Sabellaria vulgaris*, and the hydroid *Obelia bicuspidata* survived in hypoxic waters for more than one week (Sagasti et al. 2001). Taylor and Eggleston (2000) found that low DO concentrations hindered the foraging abilities of blue crabs, and increased clam vulnerability since they moved higher to the sediment surface and increased siphon extension in response to low-oxygen conditions. Benthic hypoxia and anoxia degrade fish habitat by altering the behavior, growth, production, and survival of both benthic invertebrates and mobile vertebrates (Breitburg 1992).[13]

Status and trends of fish kills and dissolved oxygen

In freshwater streams, DWQ use support data indicate low DO as a major cause of impairment in the Neuse River basin (132 mi), Chowan River basin (46 mi), Pasquotank River basin (40 mi), Roanoke River basin (24 mi), Tar-Pamlico River basin (13 mi), and White Oak River basin (8 mi) (Table 2.25). In estuarine waters, low DO was a major source of impairment in the Cape Fear (5,000 acres) and the Pasquotank river basins (1,125 acres) (Table 2.15). Although there is a direct relationship between eutrophication and low DO, use support data did not consistently show significant DO impairment where chlorophyll *a* impairment was high. This inconsistency may be due to highly variable and complex environmental conditions or DWQ monitoring limitations.

An analysis of DO data (<www.marine.unc.edu/neuse/modmon/results/results.htm>) from Neuse River MODMON stations indicated:

- Benthic and pelagic respiration are capable of fully depleting the oxygen pool in stratified bottom water in less than 5 days during summer months.
- Since the sediment oxygen demand (SOD) is much greater than biological oxygen demand (BOD) in the water column, the SOD and benthic fluxes will control how the estuary responds to long-term reductions in nutrient loads.
- Oxygen depletion is positively correlated with the accumulation of organic material in the sediments from water column production (algal blooms) or external organic matter loading and appropriate environmental conditions.
- Low-oxygen conditions occur more often and for longer duration in deeper portions of the water column. During the summer of 1997, these conditions caused lethal and sublethal stress of benthic infauna in the deeper sections of the estuary. The benthos affected included species that are important forage for demersal fish species, such as spot and croaker.

The Lower Cape Fear River Program (UNC-W) reported that low DO continues to be a major water quality problem in the river system, and an occasional problem in the tidal creeks system (Mallin et al. 2002). More than one-third of the sites sampled on the Cape Fear River and its tributaries were impacted by low DO, with lower DO in the blackwater rivers than in the mainstem of the Cape Fear. Low DO in the blackwater systems occurs naturally because decaying vegetation on the swamp floor elevates BOD and consumes oxygen from the water. Oxygen levels are generally lowest during the summer and during hurricane years. Biochemical oxygen demand loading appears to be highly dependent on stream flow. BOD at most sites in 2000-2001 averaged around 1.0 mg/l. However, because river water quality was affected by hurricanes in three of the five years, the data are not thought to be representative of "background conditions," but do provide understanding of the system's response to storm events. Recent

[13] Refer to the Soft Bottom Section for additional information on the impact of nutrient enrichment, low oxygen, and dinoflagellate blooms on clams. The Shell Bottom Section also contains information on the effects of eutrophication on fish habitat.

research in Coastal Plain systems has determined that nitrogen and phosphorus loading to blackwater streams can lead to increased BOD (Mallin et al. 2001a). Nitrogen loading can cause algal blooms, which die upon entering deeper rivers and become sources of BOD. Phosphorus loading directly stimulates bacterial growth, which increases the BOD load, thus leading to reduced DO and degraded fish habitat.

In conclusion, low-oxygen conditions have been documented to cause fish kills in multiple river basins in North Carolina. While hypoxic and anoxic events can occur naturally, eutrophication aggravates low-oxygen conditions. *Coastal research and monitoring needs to continue to improve our understanding of the processes of hypoxia and anoxia and the effect on fish populations. Efforts to reduce nutrient loading from point and nonpoint sources in the Neuse, Tar-Pamlico, and Cape Fear river systems, where the largest number of fish kills have occurred, should continue and be increased as necessary.* Of these river systems, the Cape Fear is the only river that does not have Nutrient Sensitive Waters classification and associated nutrient reduction strategies. *Implementation of mandatory riparian buffers along the Cape Fear, as well as other strategies, should be considered.*

Sediments

The dynamic process in which the physical energy of waves, tides, and currents is transferred to the shoreline ultimately results in the erosion, transport and deposition of sediment in aquatic systems. Shorelines will respond differently to wave and current energy, depending on the source and magnitude of energy, topography of land, substrate, and vegetative cover. Shoreline erosion and sediment transport are ongoing natural processes (Riggs 2001). However, erosion and sediment loading can be accelerated by human activities and sea level rise. Excessive sediment loading is considered a pollutant in aquatic habitats.

High sediment levels in the water column increase turbidity. Increased turbidity reduces water clarity, which in turn reduces primary production by phytoplankton and submerged aquatic vegetation (SAV) (North Carolina Sea Grant 1997). The reduction in light availability due to turbidity is the primary limiting factor of SAV distribution.[14]

Excessive suspended sediments can impact aquatic animals by clogging gills and pores of juvenile fish and invertebrates, which can result in mortality or reduced feeding (Ross and Lancaster 1996). Increases in the amount of nonfood particles ingested by shellfish and polychaetes lowers the nutrient value of their diet and their growth rates (SAFMC 1998). Excessive sediment loading from nonpoint sources can gradually fill in creeks and small waterbodies over time, reducing the depth and width of channels. This, in turn, alters currents and can bury benthic organisms, including entire oyster or mussel beds (P. Peterson, UNC-IMS, pers. com.; Schueler 1997). Successful recruitment of invertebrate larvae may also be reduced (SAFMC 1998; Reilly and Bellis 1983; Hackney et al. 1996; Peterson et al. 2000b; AFS 2003). Increased turbidity has been shown to lower feeding success and efficiency of adult and juvenile visually oriented predators such as bluefish, and pompano (Lindquist and Manning 2001), or to disrupt spawning migrations and social hierarchies (Reed et al. 1983).

Suspended sediment absorbs toxic chemicals, heavy metals, phosphorus, and bacteria, providing a mechanism for pollutants to be transported further downstream, where they may be ingested by filter feeding fish and invertebrates (Steel 1991). Fecal coliform and other pathogenic bacteria also survive longer in turbid water (Schueler 1999). Sedimentation removes these pollutants from the water column but stores them indefinitely. For example, results from the MODMON project have estimated that the amount of nitrogen and organic carbon stored in the upper 2 cm of bottom sediments is ten times more than the amount of total nitrogen content in the entire 3-4 m water column (Luettich et al. 1999). Once bottom sediments are resuspended, the contaminants can be released back into the water column. As the

[14] Refer to the SAV section for more information on the relationship between sediment loading and SAV, and their status and trends.

oxygen of the water near the sediment interface is reduced, the release of phosphorus, iron, and manganese increases markedly (Wetzel 1983).

Sources of turbidity and sedimentation

The primary human sources of increased sediment loading include most land disturbing activities such as building and road construction, post-construction stormwater runoff from urbanized areas, agriculture, timber harvesting, animal operations, mining, and removal of vegetated buffers (DWQ 2000b). Dredging, mining, and boating activities resuspend bottom sediments. Bottom disturbing fishing activities that generate turbidity in the water column include bottom trawling, clam kicking, and hydraulic clam dredging.[15] Hydromodifications to stream channels also increase sediment loading. Municipal and industrial wastewater treatment discharges (point sources) can be a minor source of sediment. Of all the sources of sediment loading, sedimentation from agriculture has been cited as one of the largest contributors to water pollution for the southeastern states (SAFMC 1998). The EPA concluded that siltation and nutrients impair more miles of assessed rivers and streams than any other pollutant, affecting 45% and 37% of impaired rivers and streams, respectively.

Streambank erosion can be accelerated by increased flow and velocity of stormwater runoff (Beach 2002) or from bank destabilization. In naturally forested systems of the southeast, there is very little surface runoff during and after a rainfall event, since the rainwater flows slowly over vegetated land, and infiltrates the soil (Beach 2002). Increasing impervious surfaces associated with urban/suburban development, recreational facilities, industrial/commercial activities, and land transportation result in higher volumes and rates of flow into receiving streams. Bank failures can occur when stream banks are subjected to high flows, intense or prolonged use by livestock, or vehicle crossings. Sediment inputs will generally be high where erosion rates are high and shorelines are unstable. Loss of buffer zones along streambanks can greatly contribute to bank erosion. Although shoreline stabilization with vertical structures may help retain sediments, erosion is often intensified adjacent to and in front of stabilized shorelines (Pilkey et al. 1998; Crowell 1998).

The rate of erosion and resulting sediment loading along North Carolina shorelines depends on shoreline orientation, fetch, water depth, bank height, sediment composition of bank, shoreline vegetation, presence of offshore vegetation, and boat wakes (Riggs 2001). In general, all of the Albemarle-Pamlico estuarine system is in a state of shoreline recession. South of Bogue Sound, erosion is severe only in portions of drowned river estuaries such as the Cape Fear, New, and White Oak rivers, and along the ICW and navigational channels. The remaining narrow, shallow estuaries are generally not eroding, as the marshes and flats vertically accrete sediment to keep up with rising sea level. Riggs (2001) mapped the shoreline types and shoreline areas where erosion was noticeable, and areas that had been significantly bulkheaded. Shoreline erosion rates have been estimated for portions of the coast by various studies including Hartness and Pearson (1977), Stirewalt and Ingram (1974), USDA Soil Conservation Service (1975), and Riggs et al. (1978), and Hardaway (1980). Their results are summarized and compared in Riggs (2001). These studies are helpful in indicating where major erosion problems are occurring. *Updated and accurate coastwide estuarine erosion rates are needed for the CRC and EMC in determining adequate development guidelines and regulations along the coast (DCM 2002).*

An important factor in sediment loading from shoreline erosion is the effect of global climate warming on sea level rise (IPCC 1990). According to Riggs (2001), sea level is rising at a rate of approximately 1.01-1.5 ft/100 yr in North Carolina. If sea level continues to rise at the current rate, there is a 50% chance that by the year 2200, with the influence of global climate warming, the rate of sea level rise could increase two to three times greater than its current rate. An accelerated rate of sea level rise could adversely impact the water column by accelerating the rate of coastal erosion and land loss, submerging portions of barrier islands, and increasing the loss of wetlands, which filter and trap sediment and other pollutants.

[15] The impact of these gears is dealt with in greater detail in the soft bottom section of this plan.

Status and trends in turbidity/sedimentation

North Carolina has no water quality standard for total suspended solids (TSS), but point source dischargers must meet minimum federal effluent guidelines of 30 mg/l for total suspended solids. Where effluent discharges to High Quality Waters (HQWs) that are primary nursery areas, the TSS limit is 10 mg/l; other HQWs have a TSS limit of 20 mg/l. Turbidity in streams is an indication of suspended sediment conditions and water clarity. The turbidity standard is 25 NTUs in estuaries and lakes/reservoirs not designated as trout waters, and 50 NTUs in other freshwater streams (DWQ 2000b). DWQ identified turbidity as a cause of use support impairment for the 1995 – 1999 period in portions of the Cape Fear and the Neuse River basins (Table 2.25).

Sediment impairment is also included in an evaluation of habitat degradation. The DWQ, in categorizing causes of use support impairment in freshwater streams, defines "habitat degradation" as a notable reduction in habitat diversity or change in habitat quality. Habitat degradation includes channelization, sedimentation, bank erosion, scour, loss of pools or riffles, and loss of woody habitat (DWQ 2000a). Habitat degradation was identified as a major cause of use support impairment in the Cape Fear, Neuse, Roanoke, and Chowan river basins for the 1995 – 1999 period (Table 2.25), with Cape Fear having the largest percentage of stream miles impaired by habitat degradation (284 mi., 70% of evaluated streams) and Chowan the least (4 mi., 3%). Of all major categories of use support impairment, habitat degradation accounts for the greatest overall cause of impairment in all coastal river basins combined (490 mi., 37%). Use support ratings for estuarine and coastal waters do not include habitat degradation or channelization, but urban runoff, agriculture, or forestry are cited as possible sources for over half of all estuarine waters (Table 2.23).

In addition to DWQ data, water quality information is available from federal and localized university monitoring programs. Results of the USGS NAWQA program stated that total suspended solids had decreased throughout the Albemarle-Pamlico drainage system from 1980 to 1995 (Spruill et al. 1998).

Decreases in sediment and solids concentrations are probably a result of:

- Construction of new lakes, ponds, and beaver ponds in the basin, which trap solids,
- Improved agricultural soil management, including use of conservation tillage, and
- Improved wastewater management.

For the lower Neuse River, MODMON data indicate there is generally sufficient light (lack of turbidity) to support phytoplankton photosynthesis in the upper three meters of the water column (<www.marine.unc.edu/neuse/modmon/results/results.htm>). Based on results from UNC-W's Cape Fear Program in the lower Cape Fear River, turbidity appeared to be associated most with rainfall in the Piedmont and upper Coastal Plain and generally declined moving downstream, except at the maximum turbidity-mixing zone in the middle of the estuary (Mallin 2001c). Water clarity in 2000-2001 was higher than the six-year average at most stations, probably due to low river flow. Water clarity was lowest during late winter and early spring. Low water clarity is the primary reason for low phytoplankton production in the lower Cape Fear River (Mallin 2001c). In the tidal creeks monitored by UNC-W, turbidity was generally not a problem.

Sediment loads into coastal waters can be reduced through agricultural and urban BMPs. Agricultural BMPs include (DWQ 2000b; <www.chesapeakebay.net>):

- Stream bank fencing to keep livestock out of streams;[16]
- Planting vegetated buffer strips at the edge of crop fields;
- Strip cropping (different crops are alternated in rows through one field);

[16] Reduced soil loss by 40% and average sediment concentration during stormflow events by 60% (Owens et al. 1996).

- Conservation tillage (leaving unused plant material on the field);
- Sloped and vegetated ditch banks; and
- Water control structures.

Since stormwater is a major source of sediment in urban areas, structural or nonstructural urban BMPs can be used to reduce sediment loading, including (DWQ 2000b; <www.chesapeakebay.net>):

- Slope and vegetate ditch banks;
- Use of tree roots in stormwater ditches for stabilization;
- Streamside buffer zones;
- Riparian wetland restoration;
- Reduction of impervious surfaces to allow greater infiltration on land; and
- Breakwater or riprap stabilization where erosion rates are very high.

More stringent sediment controls on construction projects are still needed to reduce sedimentation in coastal waters. Several improvements and recommendations for improvements have been made by the EMC, SCC, and associated staff committees. DWQ reported to the EMC in 2002 that actions should be taken to strengthen groundcover requirements in the erosion and sedimentation control plans and improve enforcement of the erosion and sedimentation control law and rules. These recommendations (SCC 2003; B. Devane, DWQ, pers. com., 2003) included:

- *More expeditious application of land cover on disturbed sites.* Reduce the time that developers have to get groundcover in place following completion of each project phase involving grading from 15 to 10 working days, and from 30 to 21 calendar days, whichever is shorter. Draft legislation was prepared but not introduced.
- An increase in the maximum penalty allowed for initial violations of the Sedimentation Pollution Control Act. Draft legislation was prepared but not introduced.
- An increase in the use of improved technologies to replace those now being used to control sedimentation and erosion.
- Support and encouragement by the EMC and SCC for issuing significant monetary penalties for all activities found to be in violation of their Stormwater Construction General Permit, Erosion and Sedimentation Control Plan, or the turbidity standard.

Vegetated buffers are another means of effectively trapping sediment before it reaches riverine and estuarine waters. Because buffers are beneficial in reducing not only sediment loading, but also nutrients and toxins, and benefit multiple coastal fish habitats, their use should be more widely practiced or required. Although definitions and characteristics of vegetated buffers vary, a buffer is generally a vegetated transitional zone, situated between upland land use and aquatic habitats, that functions as a filter of surface water runoff (Crowell 1998). Vegetated buffers are very effective in trapping sediment as well as other pollutants from stormwater runoff (Lee et al. 1989; Gilliam et al. 1994; Williams and Nicks 1988; DWQ 2000b; Lowrance 1997). Properly constructed vegetated buffers ranging from 5 - 185 m (15 - 600 ft) have been shown to remove as much as 90% of sediment and nitrate and up to 50% of phosphorus from stormwater runoff (Desbonnet et al. 1994). Relative effectiveness is dependent on buffer width, slope, soil type, vegetative cover, quality and flow of the runoff, and size of the drainage area. *Implementation of mandatory vegetated buffers along all coastal waters should be considered as a strategy for reducing sediment loading, the largest pollutant in N.C. coastal waters. Width of the buffers should be scientifically based and may need to be larger adjacent to strategic habitat areas.*

Fecal coliform bacteria

Fecal coliform bacteria occur in the digestive tract of, and are excreted in the solid waste from, warm-blooded animals including humans, wildlife and domesticated livestock. While these bacteria are not harmful to humans or other animals, their presence in water or in filter-feeding shellfish may indicate the presence of other bacteria that are detrimental to human health (DWQ 2000b). Moreover, elevated levels

of fecal coliform bacteria suggest that pollutants, such as nutrients, sediment, or toxins, may also be entering the water. Mallin et al. (2000; 2001), studying water quality in several tidal creeks in New Hanover County, found a positive correlation between fecal coliform abundance and turbidity, nitrate, and orthophosphate. The significant correlation between bacteria and sediment was most likely because fecal coliform bacteria tend to be associated with suspended particulate matter, and survive longer when in association with sediment particles (Mallin et al. 2000). The positive relationship between coliform bacteria and nutrients was attributed to both pollutants being derived from the same sources in some instances. Also, some studies suggest that nutrient loading can stimulate growth and survival of fecal bacteria indicators (Evison 1988). *Any steps taken to reduce nonpoint sources of bacteria loading will at the same time reduce loading of other pollutants into coastal waters and improve water quality and habitat conditions.*

Because consumption of shellfish containing high levels of fecal coliform bacteria and associated pathogens can cause serious illness in humans (FDA 1995), shellfish growing waters must be closed to shellfish harvest when fecal coliform counts increase above the standard 14 MFFCC/100ml (Commission for Health Services rule 15A NCAC 18A .0900). The DEH also closes waters where a high potential for bacterial contamination exists, such as around marinas and point source discharges. Shellfish harvest closures have continued to occur over time (DMF 2001a), which has led to a reduction in available shellfish harvest areas. While closures may protect shell bottom habitat from harvesting, water quality degradation associated with high bacterial contamination is generally not advantageous for other aquatic organisms and fish. However, because shellfish filter organisms from the water column, unharvested shellfish may provide an important water quality enhancement function to the water column. *The effect of shellfish filtering capacities on water quality parameters, such as bacteria, nutrients and sediments, should be determined.*

Sources of bacterial contamination in estuarine waters

Fecal coliform originates from both point and nonpoint sources. Point sources for the purposes of shellfish area protection include NPDES wastewater discharges and other sources with identifiable origins, such as pipes emptying directly into coastal waters. Although the wastewater discharges are treated, closures are required around all NPDES wastewater discharges due to the possibility that mechanical failure could allow inadequately treated sewage to reach shellfish waters. There are five minor and three major municipal NPDES discharges located within 0.5 mi of SA waters (Map 2.18). There are also 39 minor and 10 major non-municipal wastewater discharges near SA waters. These include discharges from water treatment plants (regular and reverse-osmosis), fish houses, sand and phosphate mines, and miscellaneous industrial activities.

Current EMC rules discourage creation of new direct discharges into shellfish waters [EMC rule 15A NCAC 2B .0224]. In fact, there has been a trend to remove some direct discharges, such as in the New River, and dispose of treated effluent on land. Most wastewater discharges meet their permit limits. However, when wastewater treatment plants are found to be out of compliance with their permitted discharge limits, waters can become degraded. Facilities that are out of compliance are subject to civil penalties. *Additional funds and process changes are needed to allow local communities to more rapidly address repairs and upgrades to all aspects of the municipal waste systems, including collection and treatment systems.*

Sanitary surveys conducted by DEH (Shellfish Sanitation and Recreational Water Quality Section) indicate nonpoint stormwater runoff is the primary cause of water quality contamination in more than 90% of the areas sampled (G. Gilbert, DEH, pers. com., 2002). Sources of bacteria and other contaminants carried into coastal waters via stormwater runoff and contributing to shellfish harvest closures identified by DEH and in numerous other studies (DMF 2001a; DEM 1994; Reilly and Kirby-Smith 1999; FRANKENBERG 1995; Schueler 1999) include:

- Residential and commercial development activities (urbanization);

- Construction of impervious structures (buildings);
- Roadways, parking lots, and driveways;
- Domestic pet waste;
- Unauthorized discharges of sewage effluent;
- Failing on-site sewage systems or subsurface flow from drainfields;
- Mechanical failure of centralized sewage treatment plants or lift stations;
- Marinas;
- Animal operations;
- Agricultural croplands;
- Forestry operations;
- Hydrologic alteration (e.g., channelization, ditching, bulkheading, canals) from multiple land uses;
- Wetland loss and degradation associated with multiple land uses; and
- Wildlife.

To prevent fecal coliform contamination from on-site sewage systems, periodic inspections of on-site systems should be conducted at frequencies recommended by DEH. In addition, siting of subsurface disposal systems in soils adjacent to coastal waters should be reevaluated and revised if necessary to protect water quality.

The primary way in which urban nonpoint runoff reaches coastal waters is from storm drain outlets, residential lawns, driveways, and streets (Schueler 1999). Bacterial concentrations in stormwater discharging from storm drains has been found to be at least an order of magnitude higher than any other individual source in a watershed, indicating that the storm drain system is the most concentrated bacterial source in the watershed (Schueler 1999). Therefore, bacterial contamination tends to come from local, rather than from upstream, sources. Once in the water, bacteria can be transported downstream, but are relatively short-lived. These bacteria die more quickly when exposed to sunlight or high salinity water. Elevated bacterial levels have been positively correlated with high rainfall (low salinity), increased turbidity and suspended solids, and low temperature (Schueler 1999). Bacterial life is extended under low temperature, low salinity, and low light conditions and may be transported with sediment (DEM 1994; White et al. 2000). Fecal coliform bacteria may also be transported to shellfish-growing waters through subsurface flow. Onsite wastewater disposal systems with less than 10 cm distance (about 4 in) between the water table and the drainage trench may contribute to bacterial contamination of the surrounding groundwater and transport to adjacent surface waters (Reilly and Kirby-Smith 1999).

A number of watershed studies have been conducted to identify specific sources of bacterial contamination in a watershed. The primary causes for bacterial contamination from studies in N.C. coastal waters are listed in Table 2.29. The cause of impairment varies and is often due to a combination of factors. When hydrological alterations (i.e., ditching and draining) occur, many wetland and stream functions are removed, increasing the delivery rate of nonpoint source runoff, and decreasing the time available for bacteria to be filtered out (DEM 1994; White et al. 2000). The forestry and agricultural BMPs that were in place during these studies did not prevent fecal coliform standards from being exceeded (DEM 1994; Mallin et al. 1997).

Table 2.29. Primary causes of fecal coliform impairment in localized North Carolina studies.

Waterbody, CHPP MU	Primary causes of impairment	Reference
South River, Neuse MU	Hydrologic modifications for logging, agriculture, and development; animal grazing at stream edge	DEM 1994
Jumping Run Creek, Core-Bogue MU	Channelization, ditching, bulkheading	White et al. 2000
North River, Core-Bogue MU	Hydrologic modifications; pet and wildlife waste	Reilly and Kirby-Smith 1999
Tidal creeks, Southern Estuaries MU	Increasing impervious surfaces and population	Mallin et al. 2001b
N.E. Cape Fear River, Cape Fear MU	Swine waste lagoon spills and ruptures	Mallin et al. 1997

Some recommendations from the above referenced bacteria tracking studies for reducing fecal coliform contamination include:

- Implement more effective BMPs for forestry and agriculture, particularly where extensive hydrological modifications exist.
- Enforce existing Forestry Practice Guidelines and BMPs.
- Require advance notice before any timber harvest in close proximity to coastal waters.
- Implement innovative wetland restoration and stormwater retention techniques (bioretention areas, peat and sand filters, and constructed wetlands) to slow, capture, and filter stormwater runoff.
- Work with owners of small animal farms to restrict livestock and their waste from direct access to stream waters.
- Educate homeowners on how and why to properly dispose of pet waste.

The control of fecal coliform bacteria sources before they reach shellfish waters is the simplest and most cost effective measure for restoring water quality (Reilly and Kirby-Smith 1999). However, to effectively reduce bacteria loading, the site-specific sources must be identified. Collaborative research is underway by NCSU and NOAA to determine accurate and cost effective methods of bacterial source tracking (M. Fulton, NOAA, pers. com., 2003). *DENR should support this research since it is needed for successful restoration of bacteria impaired waters.*

In urban areas, the percentage of impervious surfaces in a watershed has been found to be a strong indicator of fecal coliform abundance (Mallin et al. 2000). Removing vegetated areas reduces the natural filter and groundwater recharge capability of the land and forces water into areas of smaller pervious surfaces. These smaller surfaces are then overwhelmed by high volumes of water, leading to standing water and flooding. As the amount of impervious surface increases, so does the amount of runoff and flooding. Mallin et al. (1998; 2000) examined the effects of land-use practices on water quality in New Hanover County and found a statistically significant relationship between percent impervious surface cover and fecal coliform concentrations among several tidal creek systems ($r^2 = 0.95$) (Figure 2.8).

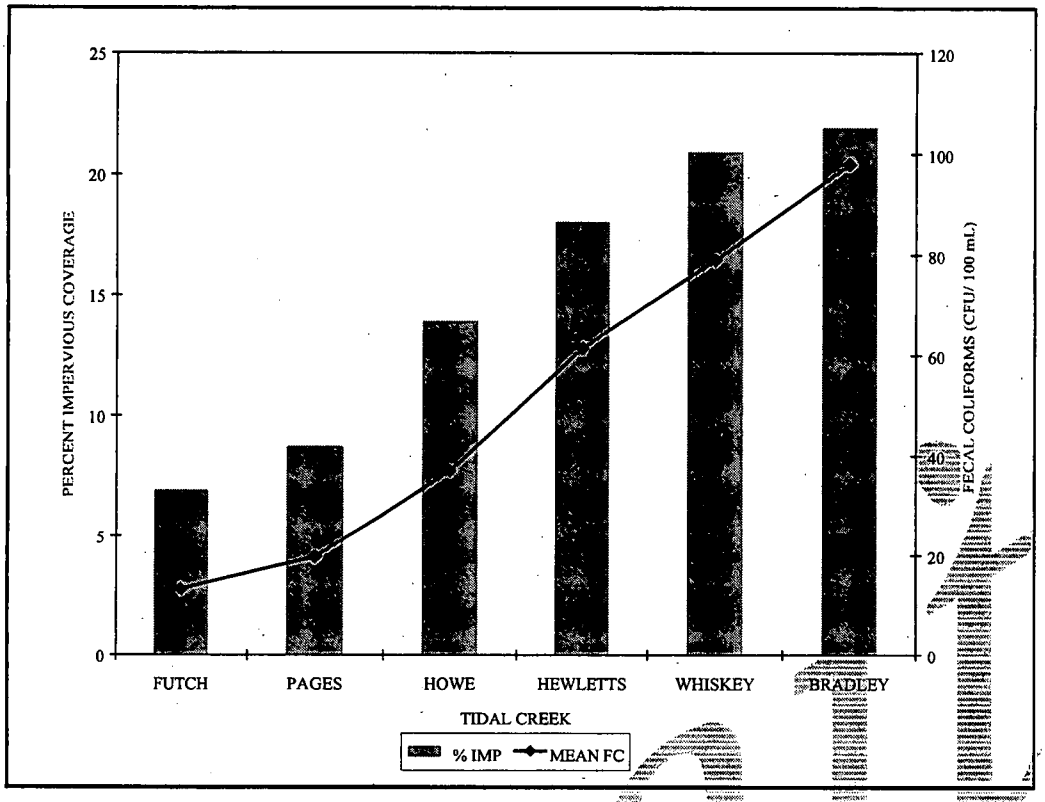

Figure 2.8. Percent watershed impervious surface coverage versus geometric mean fecal coliform bacteria counts for six New Hanover County tidal creeks. *(Source: modified from Mallin et al. 2001b)*

Several studies have found that acceptable water quality for shellfishing occurs when the proportion of impervious surface of a watershed is less than 10% (Mallin et al. 2000; Schueler 1994; Arnolds and Gibbons 1996; Barnes et al. 2001). Significant water quality and habitat degradation occurred where impervious surface exceeded 20%. A strong relationship has also been found between human population growth and closed shellfishing areas (Maiolo and Tschetter 1981; Mallin et al. 2000). *Modification of local or state stormwater rules limiting impervious surface cover adjacent to all coastal waters to approximately 12% (for the low density option) would be a scientifically based means of preventing additional water quality degradation.*

Status and trends in fecal contamination in estuarine waters

There has been a continual increase in fecal coliform contamination with increasing human population along the North Carolina coast (Maiolo and Tschetter 1981; Mallin et al. 2001b). As of 2002, 263 of 776 estuarine areas (SA waters) were on the 303(d) list because of fecal coliform contamination. The DWQ 305(b) report listed 28,435 acres (of approximately 2 million acres) of estuarine area impaired by fecal coliform contamination in coastal North Carolina (Tables 2.22 & 2.23). If the contamination is mostly from stormwater flow and other anthropogenic sources, the location of these impaired waters could indicate other nonpoint pollutants.

Trends in shellfish harvest closures reflect trends in fecal coliform contamination. Over 364,325 ac of coastal (salt and brackish) waters were closed to shellfish harvesting in North Carolina in 2002 due to high levels of fecal coliform or the potential risk of bacterial contamination (immediately around wastewater treatment plant discharges) (DEH, unpub. data). Of this total, approximately 56,446 ac of

closed shellfish waters are suitable for shellfish production. These closures have primarily affected the central and southern areas of the coast. In more recent years, additional closures have also been made in and around the Pamlico Sound (DMF 2001a). Fecal coliform abundance tends to be highest upstream and in shallow creeks and waterbodies; contamination decreases downstream and in larger open waterbodies. The areas prone to high fecal coliforms are also typically areas where shell bottom habitat is concentrated.

Between 1983 and 1985, there was a sharp decline in the acreage of estuarine SA waters that were permanently closed to shellfish harvesting (Figure 2.9). This decline was attributed to increased sampling efforts and refinements in growing area classifications by DEH (i.e., conditionally approved, open or closed), and to reductions in point source discharges in coastal waters. From 1985 through 1995 shellfish closures continually increased. Between 1995 and 2000, the total acreage of shellfish closures has fluctuated; since 2000, totals have changed only slightly.

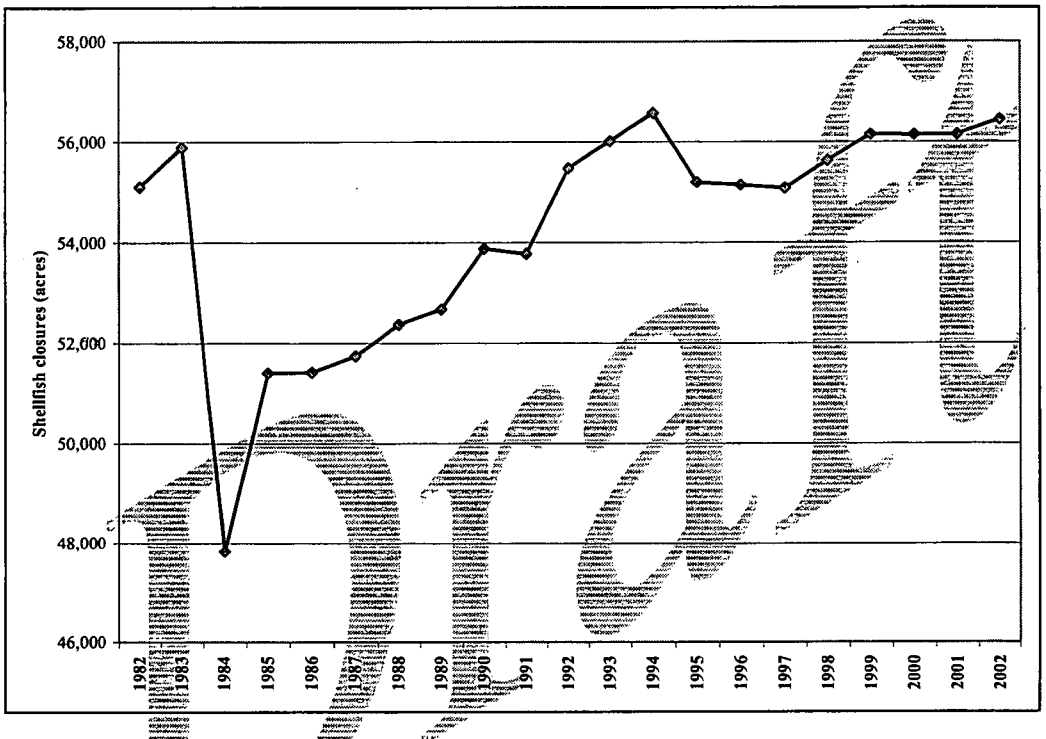

Figure 2.9. Acreage of North Carolina shellfish waters permanently closed to shellfish harvest during 1982-2002. *(Source: NC Division of Environmental Health, Shellfish Sanitation and Recreational Water Quality Section)*

In addition to the 56,446 ac that are permanently closed to shellfishing, other areas are temporarily closed during periods of high rainfall. For example, a rainfall of 1.5 inches in a 24-hour period can cause temporary shellfish harvest closures. Closures last from several days to more than a month. Large storms, such as hurricanes, result in harvest closures covering much larger areas, sometimes including all of North Carolina's estuarine waters. The conditionally approved areas are concentrated in the Core-Bogue, New-White Oak, and Southern Estuaries management units (Map 2.19a-c). Within these watersheds, permanent closures are most common in the upper reaches of tidal creeks and rivers, with conditionally approved areas occurring downstream of those areas or in the upper portions of less degraded creeks. As temporary closures have increased in frequency and duration, these closures have become an issue of great concern to the public, particularly in the southern area of the coast.

There are approximately 2,010 ac of shell bottom in the mapped areas that are currently unharvestable

most of the time due to outright prohibitions or restrictions based on bacterial concentrations (classified as "prohibited" or "conditionally approved closed"). On average, an additional 2,823 ac of shellfish waters are closed to harvest for some portion of the year ("conditionally approved open" areas), representing approximately 39% of the mapped shell bottom (12,502 acres). *Restoration efforts to reduce fecal coliform levels should target concentrated areas of shell bottom or other Strategic Habitat Area. Focusing on areas less degraded (conditionally approved areas, recently experiencing increased closures), rather than areas that have been permanently closed for many years, could also result in a greater success in habitat enhancement.*

Approximately 1,157 ac of ORW waters have been closed to shellfish since 1990. These closures have been in tributaries of Middle Sound, Stump Sound, and Topsail Sound in the Southern Estuaries MU; western Bogue, Core, and Back sounds in the Core-Bogue MU; and Swan Quarter and Juniper bays in the Pamlico Sound MU. As development activities continue, so will the number of shellfish area closures, unless changes are made to the manner in which land is developed and stormwater runoff is managed. *New or expanded stormwater outfalls to coastal shellfishing waters should be prohibited by the EMC and existing outfalls should be phased out.* Reclamation of closed areas will also become more difficult as population pressures increase. *Coordination and enhancement of rule enforcement and compliance review capabilities within DENR agencies is needed to fully enforce existing statutes and rules and minimize further water quality degradation.*

Water quality monitoring in tidal creeks in the southern portion of the coast indicates that bacterial contamination is widespread and chronic, from both point and nonpoint sources (Mallin et al. 2002). In 1995 and 1996, the mouth of Futch Creek, in New Hanover County, was dredged to increase flushing, lower bacteria levels, and improve water quality. Fecal coliform levels declined and additional acreage was opened to shellfish harvesting. The creek has continued to maintain good water quality, in terms of fecal coliform, since the mouth of the channel was dredged (Mallin et al. 2002). However, this type of water quality enhancement does not reduce the amount of pollutants entering the creeks. *Restoration of waters impaired by fecal coliform bacteria should be addressed through reductions in nonpoint source loading as well as enhancement of natural water flow conditions.*

Fecal coliform contamination in ocean waters

In the surf zone and nearshore ocean waters, fecal coliform contamination primarily comes from nonpoint runoff of stormwater. There are currently no direct discharges of treated or raw sewage to North Carolina's ocean waters. Wastewater in the coastal region is generally managed by septic systems or centralized collection and treatment facilities and package treatment plants that discharge on land or to estuarine waters. Systems that discharge into coastal rivers indirectly affect ocean waters by degrading estuarine waters that ultimately flow into the ocean. Centralized collection and treatment facilities treat their waste to kill fecal coliform prior to discharge. An important concern, however, is capacity of the collection and treatment systems to handle the rapid and expanding development in the coastal area. Collection and treatment systems are sometimes overloaded due to increasing development, heavy rainfall and infiltration and improper planning. Most problems occur during this overload period, when sewers overflow or sewage is inadequately treated. Septic systems also fail where they are not properly sited or constructed, the soil is not suitable, or they are improperly maintained (North Carolina Ocean Resources Task Force 1995).

As the coastal population continues to grow, there will be an increasing demand for local governments and the state to evaluate alternative wastewater treatment and disposal methods, including ocean outfalls. Currently, there are several studies underway in the central coastal region to recommend wastewater disposal strategies. A major concern regarding ocean outfalls, along with other sewage treatment alternatives that may remove constraints to development, is the cumulative and secondary impacts of increasing development (North Carolina Ocean Resources Task Force 1995). For example, the extent of onshore development could impact estuarine and ocean resources through associated nonpoint sources of

pollution, degrading coastal water quality. *Given the role of public infrastructure (i.e., sewage treatment capacity) in coastal development, the siting process for infrastructure should be restricted from areas that would impact sensitive fish habitats and supporting areas.*

Ocean dumping of sewage has led directly to incidents of beach pollution in several states, including New York, New Jersey, California, and Florida (Moore 1992). Adverse impacts to the fishing industry have also been documented to occur in association with dumping of sewage sludge and industrial wastes in ocean waters (Cross et al. 1985). *Offshore wastewater discharges should be prohibited in North Carolina to minimize water quality degradation to the water column.*

Stormwater runoff is currently the largest concern regarding bacterial contamination in ocean waters. The stormwater inputs are primarily a health concern due to bacterial contamination, but can also increase loading of nutrients and toxins into the surf zone. There are approximately 13 identified stormwater outfalls that discharge directly onto the beach near or lower than the mean high tide line; there are several others that discharge behind the primary dune (Maps 2.9a-c). Samples from the catch basins have found extremely high bacteria levels in the stormwater (J. Potts, DEH, pers. com.). Hanby Beach, Carolina Beach, Emerald Isle, Atlantic Beach, and Kill Devil Hills have had precautionary advisories posted due to discharge of stormwater. Hanby Beach has a permanent point source precautionary advisory because the opening of the pipe is in the water, making it impossible to see when the pipe is discharging. All of these communities, with the exception of Emerald Isle, are served by municipal or privately operated wastewater treatment systems. Centralized sewage systems have had secondary impacts to water quality and habitat by indirectly permitting denser development than would be allowed if using individual septic systems. Dense development results in increased impervious surface area and stormwater runoff.

Beach communities appear to be increasingly using "temporary" pumping of stormwater to the beach as a solution to flooding. The runoff during heavy rain events floods the streets; such flooding is largely the result of filling of wetlands, excessive impervious surface, and lack of upland stormwater retention areas. Until recently, there were no specific stormwater rules prohibiting or regulating pumping of stormwater onto the beach or into the surf zone. Any discharge into the ocean without a permit is prohibited (E. Beck, DWQ, pers. com., 2003) [NCGS 143-214.2] and any source of pollution that precludes using the waters for purposes identified in its water quality classification (i.e., swimming in SB waters) is prohibited [15A NCAC 2B.0222(2)]. In October 2003, DWQ implemented a stormwater flooding relief discharge policy. It states that, for chronic stormwater flooding, the Division staff will review proposals and work with the Shellfish Sanitation Section to ensure that water quality standards will not be impacted. Public entities are advised that non-discharge alternatives, such as pumping stormwater behind a foredune or to another land surface, are preferable to discharging directly to state waters. The town of Emerald Isle is in the process of developing such an alternative. After years of frequent emergency pumping of floodwater to the ocean, the Town recently decided to purchase a 40-acre wetland parcel that will remain undeveloped. Stormwater from flooded streets and yards will be pumped to this existing wetland site. The Town also plans to pump groundwater from the town to the wetland parcel to lower the groundwater table and increase the storage capacity around the developed portion of the town. In addition, Emerald Isle is developing a town ordinance for new development that would require the first two inches of rain to be retained on a lot, prohibit excessive removal of vegetation due to the development, and require retention of vegetated buffers along drainage ways where feasible (<www.emeraldisle-nc.org>). The Cape Fear Council of Governments has also developed a proposed alternative to the current practice of direct stormwater discharge onto beaches at Kure Beach. The Council is seeking funding through the Clean Water Management Trust Fund and other sources to construct a network of wetlands (totally approximately 20 acres) and reroute stormwater through it, eventually discharging to a canal that drains to the Cape Fear River (SC waters).

Water pollution in nearshore ocean waters is becoming increasingly problematic along the entire nation's coast. In 2000, there were reported to be nearly twice as many beach closings and advisories in the

United States as in 1999. The most frequent cause of closures or advisories was stormwater runoff (<http://www.nrdc.org/>, 2001). The apparent increase in closings, however, may be due to improved or expanded monitoring along the oceanfront. *Additional permits for stormwater outfalls on ocean beaches or nearshore waters should be prohibited by the EMC. Alternative stormwater management strategies should be implemented, similar to the efforts underway by Emerald Isle, to phase out existing stormwater outfalls and encourage land application.*

Potential sources of water quality degradation include leaching from failing or improperly functioning sewage systems or drainfields, or where septic systems become exposed or located below mean high water due to erosion. Storm-damaged septic tanks may cause contamination for a short but concentrated period in localized areas. Table 2.30 shows the number of septic tanks in need of repair, replacement, or relocation following Tropical Storm Dennis and Hurricane Floyd. In the past, the eastern ends of Ocean Isle and Holden Beach have had to relocate septic tanks and homes on a regular basis following large storm events. Leakage from systems either with inadequate setbacks from ocean waters due to erosion or not designed to handle heavy use by renters may cause gradual contamination to nearshore waters. Recent research has demonstrated that septic tank leakage in this area has caused elevated fecal coliform and nutrient loading to nearby streams and tidal creeks (Cahoon et al. submitted). *More detailed monitoring is needed to assess the extent oceanfront septic systems are causing degradation to nearshore coastal waters.*

Table 2.30. Number of known coastal septic tanks damaged by Hurricane Floyd or Tropical Storm Dennis in need of repair, replacement or relocation. *(Source: D. Moffitt, DCM, pers. com., 2002)*

Beach community	Number of septic tanks damaged	
	Post-Trop Storm Dennis	Post-Hurricane Floyd
Nags Head	35	
Rodanthe	6	
Buxton	1	
Atlantic Beach	2	
Pine Knoll Shores		3
Emerald Isle		31
Oak Island		114
Holden Beach		36
Total	44	184

The DEH Shellfish Sanitation and Recreational Water Quality Section of DENR has the responsibility for initiating a recreational water-quality-monitoring program in ocean and estuarine waters. The primary purpose of the program is to protect public health. In 2000, the Beaches Environment Assessment and Coastal Health (BEACH) Act was implemented for the purposes of improving the quality of beaches and coastal recreation water.

The Act allocates funding for states in the form of grants to:

- Develop or revise water quality criteria and standards;
- Implement studies to assess potential human health risk from exposure to pathogens;
- Develop appropriate and effective indicators and methods for improving detection in coastal recreational waters of the presence of harmful pathogens; and
- Improve monitoring and public notification programs.

Implementation of this act will provide much needed information on the water quality condition of North Carolina's coastal waters and the impact of coastal development and other activities on water quality. The Beaches Act provided additional funding to allow for more beach sampling in North Carolina. There

are currently 225 stations in ocean and estuarine waters that are sampled at different frequencies. Following EPA recommendations, *Enterococci* is used as the indicator organism for contamination. Sites are ranked as Tier I to III based on the level of swimming use, with specific standards at each tier for the acceptable level of *Enterococci.* If the swimming standard is exceeded, warning signs are posted temporarily at swimming sites.

Toxic chemicals

A toxic substance is defined in the North Carolina Administrative Code [15A NCAC 2B. 0202(36)] as "any substance or combination of substances ... which after discharge and upon exposure, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, has the potential to cause death, disease, behavioral abnormalities, cancer, generic mutations, physiological malfunctions (including malfunctions or suppression in reproduction or growth) or physical deformities in such organisms or their offspring or other adverse health effects." Potentially toxic chemicals found in the water column include heavy metals, pesticides, dioxins, petroleum hydrocarbons (e.g., oil), polycyclic aromatic hydrocarbons (PAHs), chlorine, polychlorinated biphenyls (PCBs), antifoulants, ammonia and pharmaceuticals. Many of these chemicals occur naturally (e.g., heavy metals), while others are created almost entirely by humans (e.g., pesticides). Below is a brief description of these chemicals:

- Heavy metals - Metals that have a density of at least five times that of water. These include mercury, nickel, lead, arsenic, cadmium, aluminum, iron, platinum and copper. Nonpoint sources of heavy metal inputs include municipal and agricultural runoff, contaminated groundwater and sediments, industrial shipping, recreational boating, and atmospheric deposition (Wilbur and Pentony 1999). Point sources of heavy metals include industrial discharges, power plants, ocean disposal of dredged material, and marine transportation (e.g., hull paints containing butylin compounds to hinder biofouling).
- Pesticides - Chemical compounds that are typically composed of chlorinated hydrocarbons and are used as herbicides, insecticides, and wood preservatives for agriculture, aquaculture, and urban/suburban development. Examples of pesticides are Aldrin, Atrazine, chlordane, fenvalerate, permethrin, toxaphene, and DDT.
- Dioxins - By-products of pesticide production, high temperature-combustion processes, and chemical bleaching of pulp in paper production (DWQ 1997a). Dioxins are also present as trace impurities in some commercial products.
- Petroleum hydrocarbons - Compounds found in fuel-related products such as gas, oil, and grease. There are over 100 hydrocarbon compounds in gasoline as well as numerous additives. Lubricant oil also contains elements such as zinc, sulfur, and phosphorus (Jackivicz and Kuzminski 1973).
- Polycyclic aromatic hydrocarbons (PAHs) - A group of over 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances like tobacco or charbroiled meat. Compounds in the PAH group are found in coal tar, crude oil, creosote, and roofing tar, but a few are used in medicines or to make dyes, plastics, and pesticides (<http://www.atsdr.cdc.gov/tfacts69.html>, October 2002).
- Chlorine - Biocide and bleaching agent sometimes used to disinfect waste and pool water, clean clothes, and wash boats and other surfaces.
- Polychlorinated biphenyls (PCBs) - Organic chemicals containing chlorine that have properties that make them useful for many industrial and commercial applications like electrical, heat transfer, and hydraulic equipment; in paints, plastics and rubber products; in pigments, dyes and carbonless copy paper and many other areas.
- Antifoulant paints – Paints used on vessel hulls to prevent covering by marine organisms (i.e., barnacles) (Milliken and Lee 1990). Copper and organotin (e.g., Tributyltin or TBT) compounds are the most common ingredients in antifouling paints.
- Ammonia – Form of nitrogen that comes from concentrated animal operations, cleaning products, and point source dischargers. Ammonia is also a highly toxic waste product of living organisms.

- Pharmaceuticals – Chemical compounds used to treat human illnesses (e.g., Prozac, Paxil, Celexa).

Effects of toxic chemicals on fish

There are many factors affecting a chemical's toxicity to marine organisms. Some species or life stages are more sensitive than others. Eggs, and larvae in particular, are generally more sensitive to toxics than adult and juvenile life stages because they have more permeable membranes and less developed detoxifying systems (EPA 1985; Weis and Weis 1989; Funderburk et al. 1991; Gould et al. 1994). For example, larval striped bass are less tolerant of copper sulfate ($CuSO_4$) than juveniles (Kaumeyer and Setzlter-Hamilton 1982). Individuals of these early life stages often float in the water column, where toxic chemicals are more available for uptake. Because of their water column orientation, early life stages of fish are the primary focus of this section.

Regardless of the life stage affected, some chemicals are more inherently toxic to organisms than others. For example, some pesticides and metals (i.e., toxaphene, TBT, mercury) cause acute mortality to fish or shellfish at very low concentrations (approximately 1 part per billion or less), whereas others (i.e., chromium, atrazine) can cause toxic effects only at much higher concentrations (>10,000 parts per billion) (Funderburk et al. 1991). The effect on organisms also varies according to the physical and chemical properties of the water column in which they live; higher salinity water can neutralize more dissolved chemicals than fresh water, making these toxics less biologically available for uptake. There are other physiochemical conditions that can either increase or decrease toxicity of a given chemical. For example, copper is less toxic in the presence of dissolved organic matter. Cadmium toxicity, on the other hand, decreases as salinity increases due to binding to chloride.

Many toxic chemicals (especially heavy metals) are readily adsorbed on small sediment particles and eventually removed from the water column (Butler 1971; Wolfe and Rice 1972; Vandermeulen and Mossman 1996; <http://www.atsdr.cdc.gov/tfacts69.html>, October 2002). Adsorption on sediment particles allows some toxic chemicals to continue contaminating sediments of North Carolina until they degrade into less harmful substances. Bottom feeding fish may therefore be more affected by feeding on benthic organisms than from ambient chemical concentrations in the water column (Funderburk et al. 1991). However, the smaller fraction of highly soluble toxic chemicals present in the water is more bioavailable and therefore more toxic to aquatic life.

Toxic chemicals can also affect growth, reproduction, and behavior, resulting in a reduction of stock viability (Weis and Weis 1989; Wilbur and Pentony 1999; DeFur and Foersom 2000). These effects include abnormal cell division of embryos, reduced survival of embryos, malformation of larvae, and slowed development (Weis and Weis 1989). Some toxic chemicals may disrupt endocrine secretions (i.e., hormones) of aquatic organisms, which could have a corresponding effect on natural biological properties (Wilbur and Pentony 1999; <http://ca.water.usgs.gov/pnsp/rep/carp2/ abs.html>, 2002). In the Chesapeake Bay, male catfish exhibited arrested or indeterminate sexual development when their tissue contained significant concentrations of PCBs, organotins, mercury, DDT, and DDT metabolites (deFur and Foersom 2000). Small amounts of pharmaceuticals such as Prozac and birth-control drugs are also finding their way into U.S. rivers and streams. In mosquitofish, exposure to anti-depressant drugs caused delayed sexual maturation (<www.cnn.com/2003/TECH/science/11/14/coolsc.frogs.fish/index>, November 2003). The prevalence, sources and entire effects of hormone-altering chemicals in North Carolina are currently unknown. *More research is needed on the subject of hormone-altering chemicals in surface waters.*

Given all these factors, determining the effect of toxins on organisms and populations is a complex and difficult problem. The effects of toxic chemicals on oyster beds and bottom species are discussed later in the Shell Bottom and Soft Bottom chapters, respectively. This section primarily covers the effect of toxic chemicals on pelagic species of various life stages.

The acute and chronic toxicity of selected chemicals on a few pelagic species are listed in Table 2.31. The effects of environmental pollutants on early fish life stages are listed in Appendix I. Based on the limited number of chemicals for which data are available, the water quality standard is less than the acute and chronic toxicity level for the selected pelagic species and early fish life stages. However, these data are mostly from anadromous species and based on laboratory tests to determine acute levels of mortality, which are difficult to translate into ecosystem-level effects in very complex chemical and biological environments (Weis and Weis 1989; Funderburk et al. 1991).

Table 2.31. Literature values for measured toxicity of selected chemicals on selected pelagic species. *(Sources: DWQ water quality standard and Funderburk et al. 1991)*

Chemical	Freshwater quality standard[1]	Saltwater quality standard[1]	Acute/chronic or sublethal toxicity[1]		
			Atlantic menhaden	American shad	Striped bass
Heavy metals

[a] Toxicity tests conducted in freshwater

[b] Toxicity tests conducted in saline water

AL = Values represent action levels as specified in [2B .0211 & .0220]; N = There is also a narrative description of limits in [2B .0211]; ND = no data.

The values are meant to provide a relative indication of potential effect. End times and exposure times vary, and life stages were pooled for calculating means.

Because toxic contaminant concentrations (especially heavy metals) in the sediment far exceed concentrations in the water column (Steel 1991), resuspension can be a major problem in areas where fine-grained sediments predominate. These fine-grained sediments are common in sheltered creeks and small trunk estuaries, or in the deeper regions of larger estuaries. Heavy metal contamination in these areas is of particular concern because they cover the majority of designated nursery areas, where young fish gravitate in spring and summer. Heavy metals and other volatile chemicals are most toxic in freshwater systems. Therefore, anadromous and low-salinity nursery areas are probably the most sensitive to heavy metal contamination. Documented concentrations of toxic chemicals in the sediment were the highest in low-salinity areas with limited tidal flushing and high river discharge (Riggs et al. 1989; Riggs et al. 1991; Hackney et al. 1998). The problem is further intensified by the timing of most heavy metal inputs, which occur during the period of heaviest runoff and pollutant loading (during spring), and the arrival of many larvae and juvenile to the nursery areas.

The coincidence of heavy runoff, pollutant loading, and fish use of nursery habitat is also a potential problem for pesticides that are primarily dispersed in spring (predominantly herbicides). The concentration of atrazine and other herbicides in the Albemarle-Pamlico system was highest in late May

and early June and decreased gradually until September; a seasonal pattern of pesticide concentration coinciding with seasonal patterns of pesticide use (<http://nc.water.usgs.gov/albe/pubs/ALBEetroabs.htm>, 2002). However, toxic effects may be less significant if the arrival of larvae is preceded by a major flushing event. Considering the typically high freshwater flows that occur during spring, this pattern may also demonstrate the acute toxicity and rapid sedimentation of many pesticides.

Aside from the direct impact of toxins on aquatic organisms, there is also the ability of toxic chemicals (especially heavy metals and dioxins) to accumulate in the tissue of animals at higher trophic level (e.g., bioaccumulation), which can cause health problems in human consumers (Wilbur and Pentony 1999). Fish consumption advisories are often the result of chemical contamination. This primarily affects large fish occupying higher trophic levels, and the effect is not limited to freshwater species. There is currently fish consumption "advice" for mercury in sharks, swordfish, tilefish, king mackerel, bowfin, largemouth bass, and chain pickerel caught in waters south and east of Interstate 85 (<http://www.epi.state.nc.us/epi/fish/>, 2003). Site-specific advisories for dioxin have been given for Albemarle Sound, lower Roanoke River, and Welch Creek in Beaufort, Martin, and Washington Counties.

Sources of toxic chemical pollution

Due to the settling of suspended particles in estuaries, heavy metals, dioxin, and PAH contamination usually reflects localized impacts from point and nonpoint sources, although high flow events can result in resuspension and redeposition of metal-contaminated sediments far from their original sources (Steel 1991). Riggs et al. (1989) found the highest concentration of toxic chemicals in the sediment near point sources and on the surface sediment. The concentration of toxic chemicals in deeper sediment cores was as much as 100 times less than surface concentrations.

Upon entering the water column, many organic compounds will not persist for very long because of their inability to blend, volatility, biodegradability or the effects of weathering (Jackivicz and Kuzminski 1973). The organic molecules that do persist either remain suspended in the water column, concentrate on the surface, or settle to the bottom. The portion of oil that reaches the bottom may persist for several years (Olsen et al. 1982). Lead compounds from gasoline additives have a tendency to sink to the bottom (Chmura and Ross 1978). The degradation (half-life) of pesticides such as malathion, parathion, endosulfan, fenvalerate, chlorpyrifos-methyl, methanidathion, and diazinon in seawater ranges from 2.2-17 days (Walker 1977, Cotham and Bidleman 1989, and Lacorte et al. 1995). However, the toxicity and longevity of degradation products must also be considered in evaluating water quality.

Activities contributing to heavy metal contamination include urban/suburban sprawl, dock and marina development and operation, boating activity, dredge spoil disposal, automotive transportation, industrial shipping, industrial emissions, and pesticide use (Wilbur and Pentony 1999). Potential sources of heavy metals from these activities include anti-fouling paint, zinc plates on boats, fuel, runoff from parking lots or other road surfaces, and wood preservatives leached from dock structures (EPA 1985; Marcus and Stokes 1985; Sanger and Holland 2002). Mercury and arsenic are no longer used in antifouling paints due to their toxicity (Bellinger and Benham 1978 in Milliken and Lee 1990). Tributyltin (TBT), another toxic metal compound used in antifouling paints, was restricted on non-military vessels by the Organotin Antifouling Paint Control Act of 1988 (Milliken and Lee 1990). The use of TBT-containing paints for coating the hulls of military vessels has been either officially discontinued or is currently in the process of being phased out.[17] Ports are also a potential source of toxins. Increased boat traffic and transport of

[17] Currently, most Navy, MSC [Military Sealift Command], USCG [United States Coast Guard], and Army ships have steel hulls with copper-based antifouling paints. Paints containing tributyltin (TBT) are still found on some aluminum-hulled small craft because some copper-based paints are incompatible with aluminum hulls. Currently, TBT-based antifouling paints are found on approximately 10-20% of small boats and craft with aluminum hulls. The numbers of vessels from the respective Armed...

petroleum products and other toxic materials increase the chance of spillage into the water column.

Runoff from impervious surfaces such as roads and parking lots appears to be one of the major sources of heavy metals in estuaries and nearshore ocean waters. A study in the lower San Francisco Bay found that half of the cadmium and zinc in the bay came from tire wear (Beach 2002). Lead originated primarily from diesel-fueled vehicles and half the copper in the bay was derived from brake pad wear. An additional 25% of the copper came from atmospheric emissions. In Maryland, a study of suburban watersheds with little industrial activity found that metals from lawns, roads, and automobiles accumulated in sediments at levels toxic to aquatic life (Hartwell et al. 2000). In the Charleston, S.C. area, Lerberg and Holland (2000) found a strong correlation between increasing impervious surface coverage in tidal creek watersheds and the cumulative level of contaminants in tidal creek sediments. *Because pollutants associated with roads, parking lots, and associated transportation are a significant source of toxins and other pollutants to the water column, efforts should be taken by DOT to minimize impacts by 1) designing roads to retain stormwater runoff in natural and vegetated upland or wetland areas; 2) designing roads and parking lots to minimize impervious surfaces; 3) improving water flow through transportation structures; 4) monitoring of BMPs; and 5) incorporating BMP design criteria to enhance control of bacteria.*

Studies of heavy metal concentrations in the sediments of the Pamlico and Neuse Rivers found surface sediments in the vicinity of known point sources significantly more enriched than subsurface sediment in the Neuse River (Riggs et al. 1989; Riggs et al. 1991). In the Pamlico River, heavy metal enrichment was generally less severe than in the Neuse River. In the Pamlico and Neuse rivers, individual waste treatment plants, marinas, industrial plating facilities, and military facilities were identified as probable sources of heavy metal enrichment (Steel 1991). *Determining the distribution and concentration of heavy metals and other toxins in bottom sediments throughout the coast is needed to comprehensively assess potential threat to the water column.*

Copper, chromium and arsenic (known collectively as CCA) comprise the most common wood preservative in the U.S. (Weis and Weis 1994). CCA-treated wood preservative has been shown to leach copper, chromium-VI, and arsenic into adjacent sediments and to impact marine benthos (Weis and Weis 1994; Weis et al. 1998). Among CCA chemicals, copper appears to have the most toxic effect on marine organisms and also consistently appears to leach the greatest amount (Weis and Weis 1994). The area of significantly elevated heavy metal concentrations in the sediment can extend as much as 10 m beyond CCA-treated shoreline structures (Weis and Weis 1994; Weis et al. 1998). EPA is requiring new labeling on all CCA products specifying that no use of CCA be allowed after December 2003. The wood-treating industries had already made a voluntary decision to transition away from use of arsenic treated wood (CCA). The effect of toxic chemical leaching from wood is primarily a problem along poorly flushed, freshwater and low-salinity areas. *Ultimately, research is needed to determine if marina basins in freshwater and low-salinity areas actually produce enough toxic chemicals, at the right time, to impact fish populations.*

Marinas and multi-slip docking facilities

Marina basins and their associated facilities combine many sources of toxic contamination. There are typically CCA-treated boards on docking facilities and bulkheads, and antifouling paints on the boats moored in those docking facilities. Marinas are also a source of chronic, low-level oil and gas pollution from spills that sometimes occur at their pumping stations. Although there are permit requirements for oil spill containment in marinas, there are no requirements for chronic oil pollution. *The impact of chronic oil pollution on nursery areas is unknown and needs future research.* In addition, marina facilities

Forces branches estimated to have TBT coatings are: Navy-56, USCG-50, MSC-0, Air Force-50, Army-11 (U.S. Navy and EPA 1999). It is unknown how many of these vessels have operated or presently operate in North Carolina waters, or if the policy regarding TBT use has changed since the date of the reference's publication.

include boat workshops and parking lots located immediately adjacent to coastal waters. By themselves, marinas pose relatively little threat to coastal fish habitats. However, development pressures associated with them can be more threatening (i.e., increased boating, upland development, and shoreline stabilization).

The Coastal Resources Commission (CRC) defines a marina as "any publicly or privately owned dock, basin or wet boat storage facility built to accommodate more than 10 boats and providing permanent or temporary docking space, dry stack storage, haul-out facilities or repair services" (<http://dcm2.enr.state.nc.us/Handbook/section4.htm>, 2003).

Marinas have historically been most concentrated around high- and moderate-salinity estuarine areas (Maps 2.18a-d). According to permit records, there are approximately 440 existing marinas and community docking facilities along North Carolina's coastal waterways, with a total of 1,851 wet slips (DCM, unpub. data). Carteret county has the most marinas (approximately 100), followed by New Hanover county (80 marinas). Onslow, Beaufort, Dare and Brunswick counties have approximately 30 to 40 marinas each. The highest marina concentrations are found in the Southern Estuaries (4 mi. of shoreline/marina) and Core/Bogue (5 mi. of shoreline/marina) management units.

Specific CAMA regulations exist regarding marina siting to minimize impacts to estuarine resources, such as shell bottom and human health. DEH rules require that waters adjacent to marinas have a buffer of closed shellfishing areas, of varying distances, around them. For purposes of this rule, DEH defines "marina" as "any water area with a structure (dock, basin, floating dock, etc.) which is utilized for docking or otherwise mooring vessels and constructed to provide temporary or permanent docking space for more than 10 boats" [15A NCAC 18A.0901]. Development that results in new shellfish closures is generally not permitted. However, there are still marinas being developed in closed shellfishing waters, which may lead to further degradation in waters already closed to shellfishing or to increase the size of the area closed.

There are also CRC regulations that address marina siting in designated primary nursery areas (PNAs). Current CRC regulations prohibit construction of new marinas in designated PNAs if new dredging is required, but allow siting of marinas in PNAs if no new dredging is required [15A NCAC 07H .0208 (b)(5)(B)]]. However, upland basins requiring an access channel through a PNA are given a variance by CRC if the dredging will not result in significant degradation of existing fishery and wetland resources and basin design provides adequate flushing [CRC 07H .0208 (b)(5)(A)]. Maintenance dredging of existing channels is also allowed through PNAs [CRC 07H .0208 (b)(1)(J)]. Current marina development tends to be occurring in lower salinity areas because many areas adjacent to high-salinity estuarine waters are already developed. These low-salinity areas are often smaller waterbodies that are important but undesignated nursery areas for anadromous and other fish. *To protect anadromous fish spawning and nursery areas from marina impacts, dredging for new marina construction and other marina-related activities that negatively impacts these fish functions should be restricted.* Map 2.4 shows some freshwater areas that have been designated as Inland PNAs by the WRC. These include mainstem sections and tributaries of the Cape Fear, New, Neuse, Tar-Pamlico, Alligator, Roanoke, and North rivers, and Currituck Sound (15A NCAC 10C .0503). The WRC-designated nursery areas are given the same consideration as MFC-designated PNAs by the CRC. However, only a small portion of these is located within CAMA jurisdiction. These inland PNAs are currently not recognized as HQW in EMC regulations. *Waters designated as Inland PNAs by WRC should be considered for reclassification to HQW by EMC, as was done for MFC-designated PNAs. Formal criteria need to be developed to classify and protect anadromous fish spawning areas that will be recognized by DWQ.*

Considering the localized effect of many toxic pollutants, marinas and possibly "non-marinas" (small docking facilities) located near sensitive nursery areas pose a particular concern. Of the marinas in coastal waters, 51 are located within 100 m of a MFC-designated Primary Nursery Area. Few Primary

Nursery Areas in freshwater and low-salinity areas have been designated by DMF. Although anadromous fish use areas have been located by DMF, designation of anadromous fish spawning areas needs to be completed. Until these important freshwater and low-salinity areas are designated, they remain vulnerable to toxic chemical pollution and other habitat impacts associated with marina development. *Designation of specific anadromous fish spawning and nursery areas and possibly additional Inland PNAs needs to be completed along the entire coast to provide protection from marina development and other potential threats.*

The issue of marina siting is complex and design preferences may differ between agencies due to each agency's primary responsibilities. For example, DWQ tends to prefer marinas designed with open water basins to enhance flushing, while DCM tends to prefer marinas designed as upland basins with a dredged connecting channel to minimize impacts to shoreline vegetation and obstruction of navigational access. Open water basins may encourage use by juvenile freshwater and anadromous species [18], but also enhance flushing of heavy metal contaminants. If upland basins accumulate toxins and attract young fish and shellfish, they could have a more negative impact on fisheries than open water basins. *Studies are needed to compare use of both upland and open water basins by young fish. Development of a comprehensive marina policy to address appropriate design, siting, operation and maintenance procedures, and cumulative impacts is needed to thoroughly address these and other impacts of marinas. This should consider, among other things, requiring the use of oil-absorbing materials around fuel and docking stations and shoreline habitat (i.e., wetlands, soft bottom). Support of the Clean Marinas Program through additional staff resources and incentives would benefit coastal fish habitat. The cumulative impact of clustered marinas should also be assessed.* The DWQ is drafting a marina action plan that could address many of the issues involved in developing a comprehensive marina policy (G. Putnam, DWQ, pers. com., 2002).

An emerging problem is the proliferation of small docking facilities, also referred to as non-marina boating facilities (1-10 boat slips) in developing coastal subdivisions. DCM permit records indicate that from 1990 to 2002, DCM issued an average of 538 permits per year along the coast for individual piers; 67 permits/year issued for non-marinas; and 10 permits/year issued for new or expanding marinas (Figure 2.10). These numbers are only estimates since they include repairs and replacements and may slightly overstate new marina/dock construction (D. Huggett, DCM, pers. com., 2003). The total number of marinas permitted/year has declined since 1990 and 1991 (31 and 16 permits/year, respectively) to about 6-13 per year. This decline is in part due to stringent permitting regulations and an increase in smaller docking facilities. The greatest numbers of permitted boating facilities with fewer than 10 slips since 1990 are in Carteret (164 permits), New Hanover (139 permits), and Dare (116 permits) counties. While the number of new and expanding marinas has declined over the years (Figure 2.10), the number of smaller docking facilities increased in the late 1990s and has shown large annual fluctuation since. The Division of Environmental Health's Shellfish Sanitation Branch is in the process of making a database to improve tracking of small docking facilities (1-10 slips) (S. Murphey, DEH, pers. com., 2001). Given the potential for degradation of nursery area function, *DENR should consider a temporary moratorium on all new small docking facilities (1-10 slips) and marinas, excluding individual private docks, until a comprehensive marina management system for all counties is developed.*

Small docking facilities (1-10 slips) may result in cumulative impacts to coastal fish habitat. Development often concentrates adjacent to areas with water access and docking facilities. The combination of heavy metal contamination from shoreline structures, antifoulant paints, bilge water, marine sewage, and stormwater runoff from roads, driveways, ditches, and adjacent development, could lead to significant degradation of primary nursery area functions. However, there is little documented proof of such degradation. *There is a need to study the cumulative impact of these small docking facilities and associated development on toxic chemical concentrations in the water column. The study should also*

[18] (Refer to Nursery function section.)

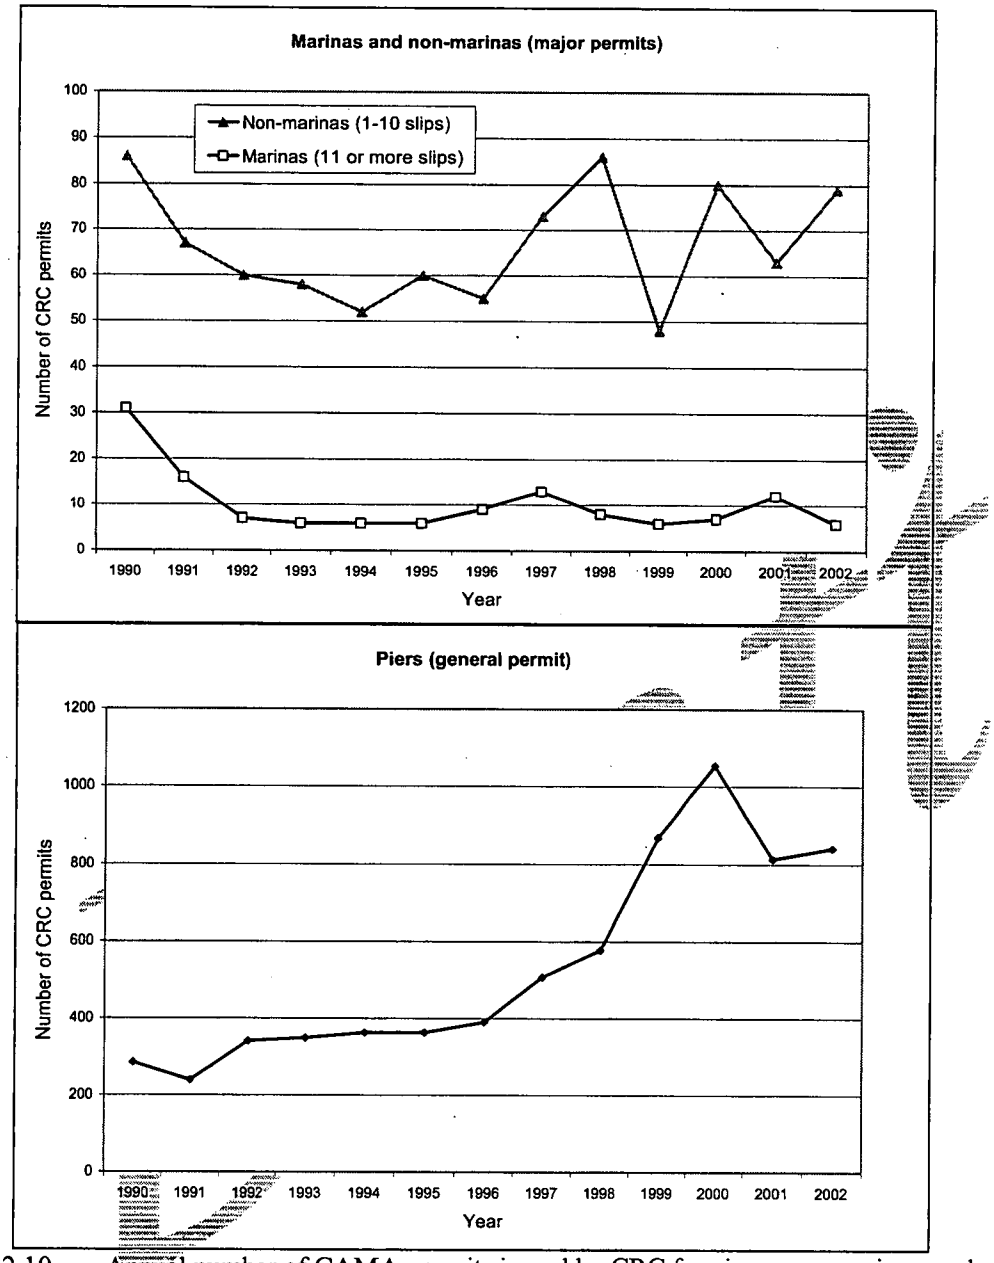

Figure 2.10. Annual number of CAMA permits issued by CRC for piers, non-marinas, and new or expanded marinas.

Piers=general permit;
Non-marinas=2-10 slips, major permit;
New or expanded marinas=11 or more slips, major permit.

compare higher and lower salinity nursery areas. The results could help in defining a rule limiting the ratio of developed public trust bottom to undeveloped shoreline near shallow, nursery habitats. There is already a CAMA rule affecting marina development by limiting the ratio of developed shoreline to undeveloped shoreline along the coastal shoreline AEC [15A NCAC 07H .0208(b)(5)], but its adequacy in preventing cumulative impacts is unverified.

Pesticide spraying

Cropland agriculture has been a consistent source of pesticides in streams, as cropland coverage has grown relatively little from 1982-1997 (Table 2.21). From 1992-1994, water samples from the Tar-Pamlico drainage basin were analyzed for 46 agricultural herbicides, insecticides, and pesticide metabolites as part of the NAWQA program (Woodside and Ruhl 2001). Although the pesticides with the highest estimated use were the compounds detected most frequently, there was not a strong correlation between estimated use and detection frequency (Woodside and Ruhl 2001). This was probably due to a number of pesticides whose estimated use was unknown (i.e., prometon). The concentration of many herbicides was greatest in spring and summer, during and immediately following application periods. The seasonal pattern of concentration was less evident for the insecticides prometon, diazinon, and chlorpyrifos (Woodside and Ruhl 2001).

Another potentially increasing threat is the effect of pesticide application over shallow water in and adjacent to wetlands to reduce mosquito levels. The Environmental Protection Agency, hoping to stem the rapid spread of West Nile virus, has recently modified pesticide use procedures to allow some spraying of pesticides over water (contrary to the pesticide label instructions) to kill mosquitoes, without having to get a permit under the Clean Water Act (<http://www.enn.com/news/wire-stories/2002/10/10112002/ap_48678.asp>, October 2002). However, these mosquito control agents can be non-selective, and are known to harm or kill larval aquatic invertebrates and fish (Weis and Weis 1989; Milam et al. 2000), which is the reason they are not labeled for use over open water. *Pesticides should always be applied according to label instruction, regardless of whether a permit is required or not.*

Milam et al. (2000) evaluated the toxicity of several popular mosquito control agents on non-target zooplankton and fish species (minnows and mosquitofish). Exposures required to kill mosquito larvae were as much as 31.4 µg/L for Dursban®, malathion, Permanone®, Abate®, Scourge®, B.T.I., and Biomist®, whereas ≥2 µg/l l of these chemicals resulted in substantial mortality (Milam and Wilhide 2000). Only malathion killed mosquito larvae before it killed mosquitofish (Milam et al. 2000). However, malathion was also identified as the cause of 64% of the pesticide-related fish kills in U.S. coastal areas between 1980 and 1989 (Key et al. 1998). The disparity between toxicity of malathion on moquitofish and pesticide-related fish kills could be the result of variable sensitivity among fish species. The toxicity of malathion was tested on grass shrimp in moderate salinity water (20 ppt) and found to be highest for newly hatched larvae (Key et al. 1998). However, the doses used to evaluate toxicity (up to 30 µg/l l) were much higher than was required to kill mosquito larvae in fresh water (1 µg/l). It may be that salinity has a buffering effect on the toxicity of malathion to both fish and mosquito larvae. *Research is needed to identify those pesticides safe for spraying over open waters and, for those pesticides whose toxicity is impacted by salinity, appropriate application rates for controlling mosquitoes.*

There are also natural pesticides and bacteria that can be used for mosquito control (Buchsbaum 1994). The bacteria *Bacillus thuringiensis israelensis* (B.T.I.) is more specific to mosquito larvae and less toxic than malathion. There is also the Integrated Pest Management approach that allows natural predators of mosquito larvae (i.e., mosquitofish, killifish) access to breeding areas. However, allowing fish access to breeding areas could disrupt or eliminate amphibians dependent on the exclusion of fish predators for their survival.

Pesticide spraying over agricultural crops is another source of pesticides in the water column. Some fish kills in coastal rivers have been found to be related to crop spraying. Pesticides can enter the water through runoff or directly due to drift from aerial applications. The North Carolina Department of Agriculture and Consumer Services administers and enforces the N.C. Pesticide Law of 1971 and N.C. Pesticide Board-adopted regulations, including crop spraying practices. The purpose of the N.C. Pesticide Program is to protect public health and safety and to promote continued environmental quality

by minimizing and managing risks associated with the legal use of pesticides. Policies on drift from aerial applications will affect the potential for toxin contamination in coastal waters and associated chronic and acute effects on fish populations.

The N.C. Pesticide Board has rules regarding aerial spraying that prohibit the application of pesticides under conditions that result in drift and adverse effects to non-target areas. Deposition of pesticides labeled toxic or harmful to aquatic life is not permitted in or near waterbodies if hazardous to aquatic life. Another aerial rule states that no pesticide shall be deposited onto any non-target area in such a manner that it is more likely than not to cause an adverse effect, unless such aquatic life is the intended target of the pesticide. An inspector will investigate whenever there is an allegation of pesticide drift to non-target sites to determine whether the pesticide was applied according to the label. *Although safeguards are in place, the N.C. Pesticide Board's policies on drift should be assessed and modified if necessary to ensure adequate protection of aquatic life and water quality.*

Recent research indicates that wetlands receiving drainage laden with toxic chemicals may indirectly impact estuarine food chains by accumulating toxic chemicals in the bacterial component of detritus, which is not affected by toxic chemicals (<http://es.epa.gov/ncer/ final/grants/96/ecoass/alberts.html>, May 2003). These toxic chemicals are then exported from the wetland to accumulate in the tissue of higher animals in the food chain. Therefore, toxic chemicals may not only accumulate through sediment pathways[19], but also through the water column in the form of floating detritus.

Status and trends in toxic chemical pollution

Several coastal studies have examined toxic chemical contamination in North Carolina's estuaries. One study of bottom sediments throughout coastal North Carolina waters found the following chemicals to be most abundant between 1994 and 1997 (in order of descending concentration): PAHs, nickel, arsenic, DDT, chromium, PCBs, and mercury. Over 1.5 billion pounds of PCBs were produced in the U.S. before they were banned in 1977. The presence of PCBs and DDT in the sediment therefore provides evidence of their persistence in the environment (Hackney et al. 1998). The study also found concentrations of other heavy metals such as antimony, copper, lead, cadmium, silver, and zinc. The sediment in 13.4% of estuarine sites sampled was nearly devoid of life during harsh summer conditions, according to the survey.

Although potentially toxic levels of trace chemicals were found in bottom sediments throughout North Carolina coastal waters, their presence also reflects the quality of the overlaying water column. Based on historical data (1950-1993), EPA's Storage and Retrieval System (STORET) the most common pesticides in surface water of the Albemarle-Pamlico system were atrazine and aldrin (<http://nc.water.usgs.gov/albe/pubs/ALBEetroabs.htm>, 2002). The Water Data Storage and Retrieval System maintained by USGS indicated relatively high concentrations of atrazine, alachlor, metalachlor, prometon, metribuzin, and metribuzin over the same time period. The herbicide atrazine is known to cause embryonic deformities in channel catfish exposed to 0.4 mg/l (Weis and Weis 1989). In total, there were 45 pesticides detected in waters of the Albemarle-Pamlico system, out of a total of 47 pesticides analyzed (<nc.water.usgs.gov/albe/pubs /circ1157/nawqa91.6.htm>, 2002).

The highest contamination levels were found in low-salinity areas with limited flushing and high river discharge (i.e., upper estuaries) (Hackney et al. (1998). This trend in toxic chemical pollution has been affected by severe weather striking the North Carolina coast. For example, after flooding accompanying Hurricane Floyd in 1999, pesticide concentrations in upper Pamlico River estuary declined by a factor of ten, while concentrations in the lower estuaries had increased slightly (D. Shay, NCSU, pers. com., 2002). One year following Floyd, however, the overall concentration of current-use pesticides was comparable to pre-hurricane levels (D. Shay, NCSU, pers. com., 2002).

[19] Refer to Soft bottom section.

Based on recent DWQ evaluations, heavy metals were a cause for impairment in 13 freshwater stream miles (DWQ 2000a). The DWQ also identified chlorine as the source of impairment in four freshwater stream miles (<1% of total rated) in coastal river basins and ammonia (NH_3) in 12 freshwater stream miles (Table 2.25). The EMC has established a water quality standard of 17 ug/L for Total Residual Chlorine, effective April 1, 2003. The Committee's move to adopt a freshwater standard for total residual chlorine (TRC) is driving the implementation of TRC effluent limitations for facilities that use chlorine or a chlorine derivative for disinfection. Such a limit may necessitate the use of a dechlorinating agent such as sulfur dioxide or a sulfite derivative. Alternative means of disinfection, such as an ultraviolet system, may be encouraged for new or expanding facilities to reduce the use of chlorine disinfection.

Toxic chemical contamination was not evaluated by DWQ in estuarine and nearshore ocean waters. However, based on a study in 1988, DWQ found concentrations of heavy metals within water quality standards in SA waters near marinas (DWQ 1990). This study also detected unidentified organic compounds (i.e., pesticides, PAHs, PCBs) at every marina examined, although the concentrations did not represent a violation of water quality standards. The current standards do not completely eliminate risk because: (1) values are not established for many toxic chemicals; (2) mixtures and breakdown products are not considered; (3) the effects of seasonal exposure to high concentrations have not been evaluated; and (4) some types of potential effects, such as endocrine disruption and unique responses of sensitive species, have not yet been assessed (<water.usgs.gov/pubs/circ/circ1225/html/human.htm> 2002). *These considerations should be a topic of future research.*

The precautionary principle regarding toxic chemical contamination should be used when data are lacking on their effects. Ideally, the fewer types and quantities of toxic chemicals to enter into the environment, the better (DeFur and Foersom 2000). Given time and normal ecological processing, some highly contaminated sites will be covered and no longer accessible, while biological agents will slowly process other sites. Lead and other heavy metals will not degrade, and dioxin only degrades slowly. *These factors should be considered when determining what chemical quantities should be allowed in the water.*

Other sources of water quality degradation

Desalination plants and marine debris are two other threats to the water column. Removal of brackish water for desalination and use as a municipal water supply is a more recent activity that has potential impacts to water quantity or quality (Copeland 1967). In rapidly developing coastal counties where wells are drawing deeper into saltier groundwater, desalination of surface waters provides another source of drinking water. There are several existing desalination facilities and some proposed facilities. The first desalination plants in North Carolina discharge wastewater into the Atlantic Ocean and sounds where the receiving area had equal or higher salinity than the effluent. Newer facilities are moving more inland to less saline waters. For example, the DWQ recently issued an NPDES permit for a proposed facility in Camden County that would discharge 430,000 gallons of salt water (~13 ppt) into the Pasquotank River where salinities range from 2-5 ppt. As of 2001, there were at least three proposed desalination plants for North Carolina in addition to 11 existing plants in the coastal area (L. Henry, DMF, pers. com., 2003). Two of these existing plants are located in freshwater areas (L. Henry, DMF, pers. com., 2003).

Effluent from desalination in freshwater areas could create isolated pockets of higher salinity water with very low diversity of species, the majority of which occupy lower trophic levels. The reduction in species diversity and isolation from the surrounding aquatic community would constitute a loss of habitat. Moreover, under natural circumstances, vertical stratification in the estuarine water column due to salinity differences creates conditions favorable to low DO, which serve to degrade bottom habitat, cause stress or mortality in benthic species and force mobile species to move (Stanley and Nixon 1992, Buzzelli et al. 2002). Similar conditions may occur artificially through effluent release in fresh water. *However, research is needed to determine if effluent from desalination plants could create the predicted effect.* Even if aquatic organisms were able to adjust to salinity changes, they may also face an imbalance of ions

that would make adjustment even more difficult (Copeland 1967; Florida DEP 1995; Goodfellow et al. 2000). Florida Department of Environmental Protection (1995) indicated that ionic imbalance could be toxic to mysid shrimp, which are an important food item in the diet of many freshwater fish species found in coastal North Carolina (Adams 1976; Whitehead 1985; Robins and Ray 1986; Page and Burr 1991; Bowman et al. 2000).

Aside from the stress of salinity change and ionic imbalance on organisms, other concerns (from Pantell 1993) include the effect of:

- Chlorine and other biocides used to clean pipes and other equipment and sometimes to pretreat the feedwater;
- Temperature of discharge waters above those of receiving waters;,
- Turbidity levels from discharge above those of receiving waters;
- Oxygen levels of discharge waters below those of receiving waters;
- Chemicals from pretreatment of the feedwater such as biocides, sulfur dioxide, coagulants-e.g., ferric chloride, carbon dioxide, polyelectrolytes, anti-scalants-e.g., polyacrylic acid, sodium bisulfite, antifoam agents, and polymers;
- Chemicals used in flushing the pipelines and cleaning the membranes in reverse osmosis plants (RO) such as sodium compounds, hydrochloric acid, citric acid, alkalines, polyphosphate, biocides, copper sulfate, and acrolein;
- Organics and metals contained in the feedwater and concentrated in the desalination process; and
- Metals that are picked up by the salty effluent touching facility components and pipelines.

The MFC has strongly objected to desalination plants in low-salinity areas due to the potential impacts and the lack of information on physical and chemical characteristics of the saline discharge. Recommendations for permitting desalination plants were presented in a draft report assembled by the Water Treatment Plant Workgroup (L. Henry, DMF, pers. com., 2002). The report identified specific information needed to evaluate the potential impact of the discharge:

- Gather more information from applicant;
- Location of project and discharge;
- Ambient water quality at discharge location;
- Proposed designed flow;
- Type of treatment process (e.g., reverse osmosis, cation exchange);
- Proposed water source;
- Dilution modeling;
- Chemical cleaning procedures; and
- Ratio of potable water to concentrate.

Using the above information and their own data/analysis, permit review agencies can evaluate the impacts on habitat and water quality. *Based on the results of dilution modeling, basic water quality parameters (flow, temperature, pH, and DO) should be identified for the applicant to monitor (Draft report, Water Treatment Plant Workgroup, 2001). If the data indicate the presence of pollutants in the discharge water, toxic chemical monitoring and toxicity testing should be required. Nutrients and ammonia should be monitored if a mass balance approach indicates excess nutrients. Finally, biological monitoring of the macrobenthic community should be required on facilities discharging more than 0.5 million gallons per day.* If the facility can demonstrate their discharge is not significantly impacting the physical, chemical, and biological environment, further monitoring could be discontinued.

Trash and other waste that is carried into the water (marine debris) accidentally or intentionally is a threat to fishery resources due to entanglement and ingestion. Entanglement can strangle or injure organisms, or impair mobility. Ingestion of plastic resin pellets, plastic bags, and other packaging by marine life can impede feeding and breathing. A 1997 study found that at least 267 species were affected by marine

debris, including numerous fish, invertebrates, sea turtles and marine mammals (Laist 1997). In 1998, the amount of trash dumped at sea was more than twice the weight of the total U.S. fishery catch (<http://www.cmc-ocean.org/mdio>, December 01, 2000). Plastics comprise about 90% of debris found floating in the water (<http://marine-litter.gpa.unep.org/facts/what-where.htm>, November 02, 2002). Surveys indicate that water based sources of trash include cruise ship operations, recreational boating, commercial fishing, offshore oil drilling, and military vessel operations. Land based sources include storm drains, sewer outfalls, and general littering. *Incentives are needed to encourage removal and proper disposal of derelict fishing gear. In addition, public education is needed to discourage littering from land or water based activities.*

Non-native/Nuisance species

There is widespread documentation that non-native/nuisance species can out-compete some native species, altering the established ecosystem, habitat, and eventually water quality (Mallin et al. 2001c). Foreign organisms in the discharge of ships' ballast water at or near ports have resulted in the introduction and spread of non-native invertebrates, such as zebra mussels and toxic dinoflagellates. Hallegraeff (1998) linked a global increase in the frequency, intensity, and geographic distribution of paralytic shellfish poisoning (a human illness resulting from consumption of shellfish contaminated with certain red tide toxins) with increased translocation of non-native dinoflagellate species via ships' ballast and import/export of shellfish products. In Australia, the sudden appearance of toxic dinoflagellate cysts was tied to exportation of woodchips (Hallegraeff 1998), an industry currently active in North Carolina. In the Chesapeake Bay and North Carolina, where the potent toxic dinoflagellate *Pfiesteria piscidia* has been reported, there is concern that the organism may disperse to unaffected areas via ballast water. Possible ballast water treatment options include chemical treatment with chlorine or hydrogen peroxide, electric shocking, ozonation, heat (35 – 45° C), deoxygenating, ballast water exchange, or reballasting. Of these alternatives, heating may be the most effective and environmentally friendly. Ballast water contamination is a worldwide maritime issue that must be addressed on an international scale, but may also be partially addressed on a regional scale. *Until treatment of ballast water is required and implemented, monitoring of port waters for algal blooms is recommended to minimize risks of introduction elsewhere (Hallegraeff 1998).* Currently the U.S. Coast Guard requires vessels to carry out an open ocean exchange of ballast water. However, this does not effectively remove or kill all organisms in the tanks (USCG 2003, unpub. doc). In 2003, the Coast Guard, under authority in the National Invasive Species Act of 1996, proposed requiring a mandatory national ballast water management program for all vessels having ballast water tanks that operate in U.S. waters and /or enter U.S. waters after operating beyond the exclusive economic zone (EEZ). Vessels entering U.S. waters after operating beyond the EEZ would be required to do one or more of the following:

- Perform complete ballast water exchange in an area no less than 200 nautical miles from any shore;
- Retain ballast water onboard the vessel;
- Use an alternative environmentally sound method of ballast water management approved by the Coast Guard; and/or
- Discharge ballast water to an approved reception facility.

DENR should work with the North Carolina Port Authority and the U.S. Coast Guard to ensure compliance with these proposed rules.

Existing management measures

There are many management initiatives that are already underway to improve conditions in the water column. Some of these programs, BMPs, and other management measures have already been mentioned. Appendix G contains a list of over 100 existing state and federal agency programs that may affect water quality. This list was compiled during the Estuarine Shoreline Protection Stakeholders Process in 1999 to identify various governmental programs that in some way affect water quality and to determine where

gaps exist or better coordination is needed. The scope of their authority, the pollutants they may affect, and a brief description are included. Some of the larger efforts are discussed below.

Stormwater Management Program

The State Stormwater Management Program was established in the late 1980s under the authority of the North Carolina Environmental Management Commission (EMC) and North Carolina General Statute 143-214.7. This program, codified in 15A NCAC 2H .1000, affects development activities that require either a Erosion and Sediment Control Plan (for disturbances of one or more acres) or a CAMA major permit within one of the following areas:

- The twenty coastal (CAMA) counties, and/or
- Development draining to Outstanding Resource Waters or High Quality Waters.

The State Stormwater Management Program requires developments to protect these sensitive waters by maintaining low- and high-density options for stormwater management, varying with water quality classification. Low-density options include limits on the maximum amount of built-upon area (or pervious surfaces), type of development (single-family residential rather than commercial), and requiring vegetative buffers and the transport of runoff through vegetative conveyances.

- Low-density built-upon area limits for High Quality Waters and freshwater ORWs are 12% or less or single family residential development on lots of one acre or more [EMC 15A NCAC 02H .1006 and .1007].
- Low-density built-upon area requirements for saltwater ORWs and areas within 0.5 mi of and draining to SA waters are 25% or less built-upon area or single-family residences on lots of 0.33 acre or more [EMC 15A NCAC 02H .1005].
- Low-density built-upon area requirements for coastal counties adjacent to waters that are not classified as ORW, SA, or HQW waters are 30% or less or single family residences on lots 0.33 acres or more [EMC 15 NCAC 02H .1005].

Development adjacent to HQW, ORW, and SA waters must also:

- Maintain a 30 ft wide vegetative buffer, and
- Transport stormwater runoff primarily by vegetated conveyances (i.e., vegetated swales are permitted, but direct pipes are not).

If low-density design criteria cannot be met, then high-density development requires the installation of structural best management practices (BMPs) to collect and treat stormwater runoff from the project. High-density BMPs must control the runoff (depending on the receiving stream classification) from the 1 in (HQW and freshwater ORWs) or 1.5 in (ORW and SA waters) storm event and remove 85% of the total suspended solids. However, within 575 ft of the shoreline adjacent to designated saltwater ORWs, development activities must comply with the low-density option.

New stormwater rules for Phase II communities have been approved by the EMC and are under final review by the Rules Review Commission. Under these rules, low-density projects in areas within 0.5 mi of and draining to SA waters can have no more than 12% built-upon area for all residential and non-residential development. All other Phase II areas can have no more than 24% built-upon area. High-density criteria require control and treatment of the first inch of stormwater runoff, an 85% average annual removal of Total Suspended Solids, and several other requirements. In addition, no new direct points of stormwater discharge or expansion of discharge to SA waters is allowed.

The Stormwater Management Program's goals are achieved through Phase I and II Stormwater permits. The Phase I permitting program for stormwater discharges was established in 1990. Phase I focuses on site and operations planning to reduce pollutant sources from certain industrial facilities, construction activities that disturb five or more acres of land, and municipal separate storm sewer systems (MS4s)

serving populations of 100,000 or more (based on 1990 census data). The large MS4s in North Carolina coastal drainages include the cities of Raleigh, Fayetteville, and Greensboro. Construction activities disturbing more than one acre require an Erosion and Sediment Control Plan approved by the Division of Land Resources.

Although Phase II of the NPDES Stormwater program was signed into law in December 1999, temporary and permanent rules to begin program implementation were not approved by the EMC until October 2002 and July 2003, respectively. Ultimately, the program will implement controls on stormwater discharges from smaller communities currently not regulated by Phase I. The Phase II program will require NPDES permits for smaller "municipal separate storm sewer systems" (MS4s) in urbanized areas, as well as construction sites between one and five acres in size. A small MS4 could be pulled into the Phase II program through automatic designation, state designation, or petitioning. Small MS4s have been automatically designated for local governments with a combined population of 50,000 or more and a density of 1,000 people per square mile. In North Carolina, there are 60 cities and 25 counties of this size that will be included automatically, based on population. The designated areas that are in eastern North Carolina include Brunswick, New Hanover, and Onslow counties; and the cities of Wilmington, Jacksonville, Greenville, Wrightsville Beach, and Leland. In addition, DWQ must develop designation criteria to determine which communities with populations of 10,000 or more, or with a density of 1,000 people per square mile, will also be put into the Phase II program, based on their potential to have an adverse impact on water quality. Other communities can be placed under the program as a rule-making petition to the EMC where there are significant water quality concerns (<http://www.epa.gov/owm/sw/phase2>, 2003). Regulated small MS4s were required to apply for stormwater permits by March 2003. Minimum requirements include:

- Public education and outreach on stormwater impacts;
- Public involvement and participation;
- Illicit discharge detection and elimination;
- Control of stormwater runoff at construction sites; and
- Post-construction stormwater management for new development and redevelopment pollution prevention for municipal operations.

To comply with the post-construction rules, local governments will have to adopt development ordinances and administer local programs that assure that new development does not cause unacceptable stormwater pollution. For example, local governments will be denied the required Phase II permit if they cannot demonstrate their stormwater programs are adequate in protection of shellfish harvesting. To be in compliance, local governments do not have to eliminate all pollutants, but must reduce the discharge of pollutants to the "maximum extent practical." The Phase II permit can require certain BMPs that are known to be effective in achieving Clean Water Act requirements in order to meet this minimum standard. As part of the Phase II stormwater regulations, local governments will have to map all stormwater outfalls in their communities. These outfalls are defined as any ditch or culvert that discharges stormwater pollution to surface waters such as creeks, sounds, or the ocean. The quality of the stormwater will have to comply with downstream water quality standards.

Neuse and Tar-Pamlico Nutrient Reduction Strategies

In response to the large number of fish kills in the Neuse River in the summer of 1995 and other concerns over deteriorating water quality, the General Assembly passed a bill that required a 30% reduction in the 1995 nutrient levels in the Neuse River basin by 2003. To meet this requirement, five "Nutrient Reduction Strategies" were developed and made effective as of 1997. Similar rules were implemented for the Tar-Pamlico river basin in 2000. The rules include:

- Riparian buffer protection rule,
- Wastewater discharge rule,
- Agriculture rule,

- Nutrient management rule, and
- Stormwater rule.

Agriculture and forestry are affected by the agriculture rule [15A NCAC 2B .0238] and the nutrient management rule [15A NCAC 2B .0232]. The agriculture rule gives farmers several options. They may participate in developing a Local Nitrogen Reduction Strategy where specific plans for each farm are developed, or implement standard BMPs such as buffers and water control structures. The nutrient management rule applies to anyone applying fertilizer on 50 or more acres of land, such as cropland, golf courses, recreational land, nurseries, or residential or commercial lawns. This rule requires training in nutrient management or development of a nutrient management plan. The wastewater discharge rule [15A NCAC 2B .0234] and stormwater rule [15A NCAC 2B .0235] will target reductions in nutrients from point and nonpoint urban development, respectively. The wastewater discharge rule allocates a total maximum discharge limit for the basin and divides that amount among different discharger groups. Dischargers also have the option to establish a nitrogen trading coalition, a group that collectively meets a nitrogen limit, determined by the EMC, equal to the combined nitrogen limits of its members (<http://h2o.enr.state.nc.us/nps/pt-sourc.htm>, 2003). The stormwater rule applies to certain large and rapidly growing communities in an effort to reduce urban stormwater runoff. Local governments are required to develop stormwater plans for new development, educate the public on stormwater issues, identify and remove illegal discharges, and identify existing development that could be retrofitted.

Although various concepts have been applied to riparian buffers, they are generally defined (Crowell 1998; <http://www.chesapeakebay.net/pol/interim.htm>, 2000) as permanently vegetated areas between a water body and upland land use that are designed to:

- Prevent upland sources of pollution from reaching surface waters by trapping, absorbing, and filtering sediments, nutrients, chemicals, and fecal bacteria.
- Maintain the natural morphology and ecosystem role of stream channels and shorelines (erosion and flood control).
- Protect fish and wildlife by supplying food, cover, and thermal protection.
- Protect other coastal habitats such as wetlands, SAV, and shell bottom through water quality and flow enhancement.

Ideally, no development is allowed in a buffer. Numerous scientific studies have documented that vegetated buffers are highly effective in removing sediment, nutrients, bacteria, heavy metals and other chemicals from stormwater runoff (Desbonnet et al. 1994; Lee et al. 1989; Gilliam et al. 1994; Zirschky et al. 1989; Groffman et al. 1991). However, the effectiveness is dependent on the width, slope, soil type, vegetative cover, quantity and quality of the stormwater runoff and size of the drainage area (Crowell 1998). In 1998, DCM staff compiled an extensive bibliography on reported pollutant removal effectiveness of various buffer widths and recommended buffer widths for various environmental objectives (Crowell 1998). The widths range from 2 to 178 m, depending on the objective and the desired amount of pollutant removal.

Forested riparian buffers are considered to deliver the greatest range of environmental benefits of any type of stream buffer (<www.chesapeakebay.net/pol/interim.htm>; Lowrance 1997). Unlike most other BMPs, riparian forest buffers accomplish multiple habitat benefits while also improving water quality. Since forested buffers are thought to remove some nutrients that grasses cannot, a three-zone riparian buffer concept was proposed for the Chesapeake Bay region to maximize buffer benefits (Lowrance 1997):

- **Zone 1** functions as an extension of the water body. Undisturbed woody vegetation remains to stabilize sediments, reduce flooding, provide woody debris, and remove some pollutants.
- **Zone 2** consists of a managed forest, where trees remain but can be managed. The primary function of this zone is removal of pollutants from surface and groundwater, while allowing some economic benefits.

- **Zone 3** may contain grass filter strips, level spreaders or other features. This zone is needed to slow runoff, infiltrate water, and filter sediment and other pollutants.

The Neuse and Tar-Pamlico riparian buffer rules were designed with this concept in mind. Zone 1 must be a 30 ft wide forested area, beginning at mean high water (MHW), where the first 10 ft remain completely undisturbed, and the other 20 ft may have limited thinning of trees. Landward of this, Zone 2 must be 20 ft wide and have dense plant cover where no fertilizer use or development is allowed. The rule applies to all perennial and intermittent streams, lakes, ponds, and estuaries. Some agriculture, forestry, and stormwater drainage activites are exempt from this rule [EMC rule 15A NCAC 02B .0233 (6)]. The EMC considers this rule to be critical to successfully reducing nitrogen. *Thorough evaluation of water quality conditions and effectiveness of the nutrient reduction strategies should be performed in the Neuse River in 2004 and the Tar-Pamlico River in 2005 and rules modified as necessary to achieve nutrient reduction goals.*

Although there are many unanswered questions regarding the effectiveness of the Nutrient Sensitive Waters (NSW) regulations in the Neuse and Tar river basins, including the 50 ft riparian buffer, nutrient reduction strategies in the Chowan River basin–which have been in place for over 20 years–have had some success. In 1979, the Chowan River basin was the first river basin to be designated as NSW. Since nutrient reduction strategies were implemented, reductions in nutrient loads have been achieved and algal blooms have been reduced in frequency and duration. The Chowan River basin met the goal of a 20% nitrogen reduction. Total phosphorus was reduced by 29% in the same time period, although the goal was 35% (DWQ 2001a). The following strategies were recommended to reduce point and nonpoint phosphorus and nitrogen inputs (DWQ 2001a):

- Convert point source discharges to land application systems.
- Require point source effluent limits of 1 mg/l for phosphorus and 3 mg/l for nitrogen in the North Carolina portion of the basin.
- Target funds from the Agriculture Cost Share Program to implement BMPs for agricultural nonpoint sources. From 1995 to 2000, over $1,942,634 of Agriculture Cost Share funds were directed to the Chowan basin.

Although a 50 ft buffer is not in place in the Chowan, this river basin has the lowest basin population (North Carolina portion only), second lowest population density, and lowest projected population increase relative to other coastal river basins (Table 2-2.1). This river basin also has extensive riparian wetland vegetation to filter pollutants from upland activities. In addition, net loss of wetlands from dredge and fill activities in the Chowan River basin, as determined from 401 permits issued, appears to have decreased since 1995. Additional information on wetland impacts and mitigation in all of the coastal river basins is provided in the Wetland Section of this plan. Although the Chowan River basin is very different from the other coastal river basins, it is an example that nutrient reduction strategies can successfully improve water quality.

Coastwide Buffer Rule

The CRC adopted a 30 ft buffer as part of the Coastal Shoreline AEC in August 2000 for all new development in the 20 coastal counties governed by CAMA. This buffer begins at the water's edge, and allows clearing of vegetation as long as no soil disturbance occurs. Although this buffer will certainly have positive environmental benefits throughout the coast, the science suggests it will be inadequate in significantly reducing pollutant loading from nonpoint runoff (Lee et al. 1989; Zirschky et al. 1989; Desbonnet et al. 1994; Gilliam et al. 1994; Groffman et al. 1991; Lowrance 1997).

Additional actions are needed to increase the preservation and establishment of riparian forest buffers in other river basins to maintain and improve the condition of coastal waters. Highest priority should be in coastal waters where fish kills are documented, shellfish harvesting is threatened or closed, where there

are primary nursery areas, and where the most pristine waters are located nearest to productive fisheries. The Neuse and Tar-Pamlico riparian buffer rule could be expanded to these areas. Additional incentive-based approaches, such as tax credits for preserving unmowed vegetated buffers should be developed and implemented. Another means of preserving highly sensitive undeveloped shoreline vegetation is through establishment or enhancement of state/local land acquisition programs.

Local initiatives

There are many local monitoring and management initiatives that have been implemented to protect sensitive resources. University and citizen water quality monitoring programs have already been discussed in the text. Other county programs are focusing on educating the public on the value of riparian buffers, developing watershed management plans, acquiring conservation easements, and restoring wetlands and riparian streams to improve water quality. *The successes of these local projects need to be well publicized to promote similar local and multiple agency projects in other areas. In addition, conservation easements need to be enforced to ensure effectiveness. Land use planning and implementation equivalent to that required by CRC in CAMA counties should be required in all coastal-draining river basins, as recommended by the Estuarine Shoreline Protection Stakeholders group in 1999.*

Needed management measures

In summary, there are many possible actions at state, local, and federal levels that could be taken to improve multiple water quality parameters. *Before implementing new measures, actions should focus on improving the effectiveness of existing regulations and water quality monitoring programs so that status and trends can be accurately assessed. Efforts should continue to reduce point source discharges and improve the quality of discharge effluent. To reduce nonpoint loading of nutrients, sediments, bacteria and toxins into the water column, a broad range of strategies should be implemented, including:*

- Accelerate land preservation and restoration activities;
- Improve and implement land use planning strategies;
- Reduce nonpoint runoff from agriculture and silviculture practices; and
- Expand or implement public outreach on coastal fish habitat, threats, and actions to reduce negative impacts.

2.5. SUMMARY OF WATER COLUMN CHAPTER

The water column habitat surrounds and supports all aquatic organisms and connects all coastal fish habitats. Consequently, clean and healthy waters are critical to the overall viability of coastal fish habitats and aquatic organisms. The general distribution of fish within the water column is determined by the physical and chemical properties of each unique water body (i.e., salinity, temperature), while the abundance, diversity, and health of coastal fish and invertebrates are strongly influenced by water quality conditions (i.e., oxygen, turbidity, nutrients). The water column provides the necessary medium for spawning and transport of eggs and larvae to habitats favorable for survival and growth. In addition, coastal waters are an important source of primary production, providing food for the survival of early life stages of aquatic organisms. Another critical function of the water column is to support other important food sources for pelagic species, such as river herring, bluefish, and Spanish mackerel, and to serve as a critical corridor for migration. Particularly important areas of the water column include inlets, shallow estuarine nursery areas, anadromous fish spawning and nursery areas, and the nearshore surf zone.

Well-documented occurrences of low oxygen events, fish kills, and harmful algal blooms during the 1980s and 1990s provided visible indicators that coastal waters were declining in quality. Although severe water quality problems are variable and appear to have diminished in recent years, many coastal waters remain impaired. The primary threats to the water column are hydrological modifications and water quality degradation.

The hydrology of North Carolina has been altered dramatically, with over 2,000 dams obstructing and modifying water flow to the coast, numerous surface water withdrawals, and extensive channelization of streams. Physical obstructions in streams from structures such as dams and road crossings (fill causeways, culverts), as well as alteration of flow conditions, are a major threat to anadromous fish species, some of which are classified as Overfished by Division of Marine Fisheries (American shad, the central/southern stock of striped bass, and the Albemarle Sound stock of river herring). Removing obstructions and restoring flow in streams and rivers have been highly successful in some areas for restoring striped bass and American shad populations and should continue to be a high priority.

Water quality degradation affects aquatic organisms in many ways. Excessive sediment loading increases turbidity and sedimentation, which can result in a decrease in biological productivity, clogging of fish gills, reduced recruitment of invertebrates, increased mortality, and filling in of rivers and creeks. Important fishery and prey species in North Carolina that are impacted by alterations or degradation of the water column include pelagic-oriented species such as blueback herring, American shad, striped bass, Atlantic menhaden, bluefish, and anchovies. The condition of the water column also influences other coastal fish habitats. For example, waters depleted of oxygen can result in extensive mortality of individuals inhabiting shell bottom and soft bottom communities. Moreover, excess sedimentation and turbidity can shade submerged vegetation, while the associated sediment can smother hard bottom communities.

Primary sources of sediment are nonpoint runoff from land disturbance associated with building and road construction, agriculture, forestry, mining, and removal of vegetated buffers. A predicted increase in the rate of sea level rise will accelerate coastal erosion and impact sedimentation-related issues. Division of Water Quality data show the greatest impairment to coastal freshwater streams is due to not only excessive sediment loading but also low dissolved oxygen.

Low dissolved oxygen has been responsible for many fish kills in coastal river basins, especially the Neuse, Cape Fear and Tar-Pamlico. The estuarine species most frequently affected by fish kills have been menhaden and flounder; the most frequently reported freshwater species have been sunfish and catfish. Such oxygen depletion can occur naturally, but is greatly aggravated and intensified by eutrophication. This excessive loading of nutrients can also contribute to toxic algal blooms and may contribute to *Pfiesteria* outbreaks. Primary sources of excessive nutrients in the water column include point source wastewater discharges, and nonpoint runoff from crop agriculture, animal operations, urban development, and air emissions from industries and vehicles. Another serious concern for estuarine and ocean water quality is bacterial contamination, both for habitat and health reasons. Fecal coliform contamination in estuarine waters is a major cause of water quality impairment, originating primarily from nonpoint sources. Bacterial contamination has resulted in consistent increases in shellfish harvest closures over time, including closures in Outstanding Resource Waters, North Carolina's highest quality waters (over 1,000 acres closed in ORW waters since 1990). When stormwater is discharged on ocean beaches, it contaminates the surf zone with not only bacteria, but also a variety of other toxins. Runoff from roads, agriculture, and marina-related activities are common sources of toxins in coastal waters. While toxins are a concern to the water column, these pollutants tend to settle and become incorporated into soft bottom habitat relatively quickly, where they can be resuspended or can adversely affect organisms in the bottom sediments.

Sediment, nutrient, bacteria, and toxin loading must be reduced by addressing multiple sources. These include improvement and continuation of urban and agricultural BMPs, more stringent sediment controls on construction projects, and additional buffers along coastal waters.

The water column is the most essential habitat required for the survival, growth and reproduction of fish and it greatly influences all other coastal fish habitats. Therefore, efforts are needed to minimize threats

and enhance water quality wherever possible, particularly within and adjacent to designated Strategic Habitat Areas.

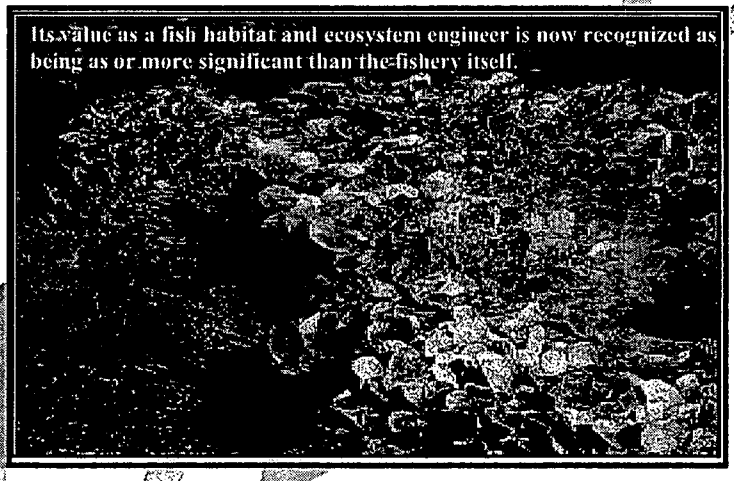
CHAPTER 3. SHELL BOTTOM

3.1. DESCRIPTION AND DISTRIBUTION

Definition

For the purposes of this plan, shell bottom is defined as "estuarine intertidal or subtidal bottom composed of surface shell concentrations of living or dead oysters (*Crassostrea virginica*), hard clams (*Merceneria merceneria*), and other shellfish." The definition is limited to estuarine waters and habitats because North Carolina's economically significant shellfish resources and their fisheries are entirely estuarine, although many species of molluscan shellfish live in fresh water and nearshore ocean waters.

In the 1990s, fisheries management agencies began to formally recognize shell bottom habitat as critical to fisheries production. The North Carolina Marine Fisheries Commission (MFC), South Atlantic Fishery Management Council (SAFMC), and Atlantic States Marine Fisheries Commission (ASMFC) all recognize the importance of shell bottom. Some define shell bottom largely by reference to the economic value of living shellfish, while others include the ecological functions of all shell bottom.



Its value as a fish habitat and ecosystem engineer is now recognized as being as or more significant than the fishery itself.

Description

Common terms used to describe shell bottom habitats in North Carolina are "oyster beds," "oyster rocks," "oyster reefs," "oyster bars," and "shell hash." Shell hash is a mixture of sand or mud with gravel and/or unconsolidated broken shell (clam, oyster, scallop, and/or other shellfish). Shell bottom can be natural or man-made. Cultch material (hard material to which oysters attach) can consist of oyster, clam, or scallop shells; gravel or marl; or other hard materials. Cultch exists naturally, as shell hash and oyster rocks. It is also planted by DMF's Shellfish Rehabilitation Program to enhance and restore estuarine shell bottom in order to increase oyster spat settlement and growth, and to promote settlement and survival of hard clams. Participants in the shellfish lease program often use cultch in their aquaculture operations.

The horizontal area of shell bottom habitat ranges in size from a few square yards of scattered shell clumps to acres of living oysters and dead shells. The habitat can also consist of many square miles of shell hash more than a yard deep. A good example of shell hash bottom habitat is present in New River, North Carolina.

Shell bottom is both intertidal and subtidal and can consist of fringing or patch reefs (Coen et al. 1999). In North Carolina, oysters accumulate on existing oyster beds, outcroppings of fossil shell beds, as well as on wedge rangia, hard clam, and bay scallop shell beds (DMF 2001a). Oysters attach to exposed roots at the margin of salt marsh, pilings, seawalls, and rip-rap. Intertidal oyster reefs in North Carolina were

characterized into three "landscapes" or combinations of adjacent habitats (Bahr and Lanier 1981; Grabowski et al. 2000). These were:

- Salt marsh landscape – on the edges and points of salt marsh away from seagrass beds
- Seagrass landscape – nestled between seagrass beds and salt marshes
- Mud flat landscape – on mud flats isolated from vegetative structure

Intertidal oyster reefs in the central and southern estuarine systems may only be a few oysters thick. However, subtidal oyster mounds in Pamlico Sound may have been several meters tall (Lenihan and Peterson 1998).

Habitat requirements

Oysters are the principal builders of natural shell bottom in North Carolina's estuaries. Marshall (1995) identified the most critical habitat for oyster populations as oyster beds and rocks, which the oysters themselves form by the accumulation of shells and oysters over time. The North Carolina Oyster Fishery Management Plan also recognized that the condition of oyster beds or rocks is the most important factor affecting oyster stock abundance because the shell material on those rocks is the most abundant and preferred substrate for the settlement of larval oysters (DMF 2001a).

The oyster's reproductive, morphological, physiological and behavioral adaptations have, in the past, allowed it to persist in immense numbers throughout the estuary (Kennedy 1991). The normal growing temperatures for eastern oyster range from 10 to 30°C (Burrell 1986). Their optimum salinity ranges from 14 to 30 ppt (Castagna and Chanley 1973). The optimum salinity for oyster larvae is somewhat lower than normal growing salinities for spat and adults (Loosanoff 1953; Chanley 1958; Davis 1958). Studies have shown that lower salinities combined with higher temperatures increases oyster mortality (Loosanoff 1953; Funderburk et al. 1991). Oyster distribution and abundance in low salinity waters is therefore limited by salinity and high temperature. However, predation by boring sponges, oyster drills, whelks, annelid worms, and starfish is also reduced in low salinity waters (Gunter 1955; Bahr and Lanier 1981). Increased mortality in the upper and lower regions of the estuary leaves moderate salinity areas with the highest abundance of subtidal oysters in North Carolina. Oyster growth in the intertidal waters varies significantly with temperature, tidal flows, and food quality and availability.

Oxygen levels and suspended sediment can affect survival and viability of oysters. Dissolved oxygen (DO) less than 1 to 2 mg/l is generally lethal or harmful to oysters, depending on the time of exposure and life stage of the oyster. Oyster eggs are affected most by suspended sediment, while larvae are slightly more turbidity tolerant, and adult oysters have significantly greater tolerance for suspended matter.[1]

Although oysters can tolerate extremes in salinity, temperature, turbidity and low dissolved oxygen, spawning success requires optimum salinities, temperatures and good water currents to disperse the larvae. Successful spat settlement and survival requires refuge from predators (Bartol and Mann 1999, Coen et al. 1999); clean, firm surfaces, preferably oyster shell (Kennedy et al. 1996); and good water circulation (Burrell 1986). Adult oysters also require adequate water circulation to deliver food and oxygen and to remove wastes and sediment.

For subtidal oyster reefs, vertical height affects growth and survival rates for individual oysters by maximizing circulation benefits (Lenihan and Peterson 1998; Lenihan et al. 1999; Peterson et al. 2000a). The vertical structure of oyster reefs physically locates the oysters off the bottom to avoid anoxic water

[1] Studies have found that suspended sediment concentrations of 250 mg/L resulted in 27% mortality in oyster eggs, 500 mg/L resulted in 69% mortality, and 1000 mg/L caused 97-100% mortality (Davis and Hidu 1969a). Larvae were slightly more turbidity tolerant, with 50% mortality occurring at 1000 to 1500 mg/L after 12 days of exposure. These researchers also documented growth reductions in oyster larvae at suspended sediment concentrations of 750 mg/L. Concentrations above 750 mg/L are representative of the amount of turbidity caused by storms or dredging activities (Davis and Hidu 1969a). Adult oysters are able to feed in water containing up to 0.4 g/l of suspended matter (Nelson 1938; Nelson 1960).

(Lenihan and Peterson 1998) or smothering by sediment (Coen et al. 1999). Lower reefs may be exposed to higher sedimentation rates and increased exposure to anoxia resulting in higher mortality rates.

Distribution

The primary shell-building organism in North Carolina estuaries, the eastern oyster, ranges from the Gulf of St. Lawrence in Canada through the Gulf of Mexico to the Bay of Campeche, Mexico and to the West Indies (Bahr and Lanier 1981). To the degree commercial fishery landings may indicate abundance, the highest documented oyster abundance along the Atlantic coast is in the Chesapeake Bay (DMF 2001a). Historically, Maryland's landings of 15 million bushels dwarfed North Carolina's highest annual oyster landings of 1.8 million bushels in 1902 (DMF 2001a).

Oysters are found along a majority of the North Carolina coast from extreme southeastern Albemarle to the estuaries of the southern part of the state to the South Carolina border (DMF 2001a). Oyster reefs occur at varying distances up North Carolina's estuaries, depending upon salinity, substrate, and flow regimes. In the wind-driven Pamlico Sound system north of Cape Lookout, oyster reefs consist overwhelmingly of subtidal beds. South of Cape Lookout, subtidal rocks also occur in the New, Newport, and White Oak Rivers (DMF 2001a). Extensive intertidal oyster rocks occur in North Carolina's southern estuaries, where the lunar tidal ranges are higher. Substantial shell hash is present in New River, eastern Bogue Sound, and along the edges of many streams and channels, such as portions of the Atlantic Intracoastal Waterway (ICW) in the southern coastal area.

In the Albemarle-Pamlico estuary, oysters were concentrated in the lower portion of Pamlico Sound tributaries, along the western shore of Pamlico Sound, and to a lesser extent behind the Outer Banks. (Epperly and Ross 1986) (Map 3.1).

Shellfish habitat and abundance mapping

The DMF Shellfish Habitat and Abundance Mapping Program began creating detailed bottom type maps in 1988. These maps are being compiled using standardized surveys from the South Carolina border north through Core Sound, along the perimeter of Pamlico Sound, and in Croatan/Roanoke sounds (Map 3.2). The program delineates all bottom habitats, including shell bottom, and samples the density of oysters, clams, and bay scallops in these habitats. This program has differentiated 24 different bottom types based on combinations of depth, bottom firmness, vegetation density, and density of surface shells. This program defines shell habitat (shell bottom) as significant cover (>30% of bottom) of living or dead shells. Some of the other fish habitats mapped by the program include salt marsh, submerged aquatic vegetation, and soft bottom. A stratified random sampling design is used to provide statistically sound shellfish density estimates by area and habitat.

As of January 2003, mapping has been completed from Carolina Beach to Ocracoke Inlet, including Core Sound. The following specific areas have also been mapped: Shallowbag Bay, portions of Pamlico Sound in the vicinity of Oregon Inlet, and South River (Carteret County) (Map 3.2). This area represents approximately 42% (222,643 acres) of the total area (about 530,000 acres) intended for mapping (Map 3.2). As of 2003, West Bay in southwestern Pamlico Sound has also been completed.

Of the entire area mapped by January 2003 (222,643 acres), approximately 6% (12,502 acres) of the bottom was classified as shell bottom (Table 3.1). The Southern Estuaries have the greatest proportion of shell bottom (17%) of the areas mapped to date. Private shellfish leases were delineated but not included in these estimates. Shellfish leases cover additional shell bottom areas in the Core/Bogue (357 acres) and New/White Oak (498 acres) of the shellfish mapping study area. As of January 2003, there were 281 shellfish leases in coastal North Carolina occupying 2,079 ac, which comprises less than 1% of the

shellfish mapping study area.[2]

Table 3.1. Shell bottom habitat mapped within Coastal Habitat Protection Management Units by the North Carolina Division of Marine Fisheries' Shellfish Habitat and Abundance Mapping Program (January 2003).

Management unit	Total area mapped		Shell bottom (intertidal)		Shell bottom (subtidal)		Total shell bottom
	acres	% complete	acres	% complete	acres	% complete	acres
Albemarle	1,687	2.8	0	0.0	33	1.9	32.8

Coastal Ocean	246	56.2	0	0.2	2	0.8	2.3
Total *	**222,643**	**41.9**	**4,820**	**2.2**	**7,681**	**3.5**	**12,501.8**

Percent (%) is the amount of shell bottom/total area mapped within each MU.
Total mapping study area is shown on Map 3.2.

The highest average shellfish density (45.5 shellfish/m^2) within the mapped area was in the Core/Bogue MU. Maps 3.3a-c show the spatial distribution of shellfish density on shell bottom.[3]

3.2. ECOLOGICAL ROLE AND FUNCTIONS

Ecosystem enhancement

Water Quality Enhancement

The direct and indirect ecosystem services of the oyster reef, such as filtering capacity, transfer of production between bottom and water column, nutrient dynamics and sediment stabilization, have been largely ignored or underestimated (Coen and Luckenbach 1998). The ASMFC reports that shell bottom provides food, refuge and nursery grounds for coastal fisheries. Shell bottom also indirectly benefits the fisheries by providing water filtration. Kennedy (1991) suggested that the filtering activities of the massive concentrations of oysters historically present in the Chesapeake Bay might have resulted in different assemblages of plankton, with fewer sea nettles, microplankton and bacterioplankton. Before the end of the 19th century, oysters in the Chesapeake Bay could filter the entire volume of the Bay in a little more than three days (Newell 1988). Newell's estimate of the filtering capacity of Chesapeake Bay oyster populations in 1988 was 325 days. Other researchers agree that the loss of oyster populations removes one potentially important means of controlling nuisance phytoplankton blooms and other negative impacts of nutrient enrichment and coastal eutrophication (Officer et al. 1982; Dame et al. 1984; Lenihan and Peterson 1998; Coen et al. 1999; Jackson et al. 2001). Jackson et al. (2001) attributed much of the decline in water quality in Pamlico Sound and Chesapeake Bay to loss of bio-filtration capacity attributable to the drastic decline (>90%) in oyster biomass.

Shell bottom enhances water quality by transferring phytoplankton production to benthic production

[2] However, the contribution of shellfish leases to overall shell bottom is unknown because they contain areas that do not meet the definition of shell bottom. So the estimates for overall shell bottom coverage are somewhat underestimated.
[3] More information on the distribution of shell bottom is provided in the Status and trends section (3.3).

through filter feeding (Officer et al. 1982; Cloern 2001; DMF 2001a; Newell et al. 2002). Increased shell bottom and oyster biomass reduce the impacts of eutrophication. After being recycled by oysters, nutrients are deposited around the base of oyster beds where nitrogen is removed (Newell et al. 2002). The organic deposits from oyster filtering can be released by erosion, sediment reworking by animals, or resuspension with possible uptake by adjacent SAV (Peterson and Peterson 1979). With more nutrients denitrified or stored in the sediment, the frequency of hypoxia (<2 mg/l of dissolved oxygen) and anoxia (no dissolved oxygen) events in the water column should decrease. The oyster shells themselves also store carbon in the form of calcium carbonate (Hargis and Haven 1999). The sequestered carbon is thus taken out of atmospheric circulation, counteracting global warming.

Habitat Modification

The oyster's structural modification of habitat is important to the estuarine system. As shell bottom increases, wave energy decreases, stabilizing sediment and decreasing erosion (Lowery and Paynter 2002). High-relief shell bottom alters currents and water flows, influencing patterns of fish settlement, predation and predator feeding success (Breitburg et al. 1995; Coen et al. 1999). On the down-current side of the reef, flow velocity is reduced and larval fish species can maintain their positions during the high-flow portions of the tidal cycle (Breitburg et al. 1995). Oyster reefs can also constrict tidal flow to certain areas, resulting in island formation (Bahr and Lanier 1981). By reducing wave energy along the shoreline, shell bottom aids in stabilizing creek banks and reducing salt marsh erosion (Bahr and Lanier 1981; Dame and Patten 1981; Marshall 1995; Breitburg et al. 2000).

The presence of shell bottom reduces turbidity by filtering water and physically trapping and stabilizing large quantities of suspended sediment and organic matter with the shell structure (Haven and Morales-Alamo 1970; Dame et al. 1989; Coen et al. 1999; Grabowski et al. 2000). This, in turn, improves water clarity, which increases productivity of the water column and SAV. The reduction in turbidity has a positive effect on SAV by increasing light penetration to the plants, creating more suitable conditions for SAV growth, survival, and expansion (Meyer and Townsend 2000). As an example, prior to large-scale losses of shell bottom in the Chesapeake Bay, bay waters were reported to be much less turbid than current conditions, which allowed submerged aquatic vegetation to thrive (Coen et al. 1999; Jackson et al. 2001). Because of these ecosystem benefits provided by oysters to other habitats, Lenihan and Peterson (1998) proposed that oysters might now be more economically valuable as a habitat than a fishery.

Productivity

Primary producers on shell bottom include algae (epiphytic microalgae, attached macroalgae) and organic films of bacteria and fungi. These organisms provide food for resident secondary consumers. Many crab species (including the mud crabs and pea crab), barnacles, soft-shelled clams, hard clams, mussels, anemones, polychaetes, amphipods, hydroids, bryozoans, flatworms, mussels, and sponges make up the oyster reef community. All of these species recycle nutrients and organic matter and many become prey for finfish, shrimps and blue crab (Bahr and Lanier 1981). Grass shrimp (*Palaemonetes* spp.), an important link in food webs, prefer oyster reefs to other surfaces when avoiding predators (Posey et al. 1999). Resident species (e.g., gobies) are significant zooplankton predators.

Live oyster shell bottom also enhances secondary productivity in the estuary by providing hard, complex substrate, allowing colonization by an abundance of plants and animals on the shell substrate. This in turn supports many resident and transient fish and invertebrates that are ecologically and economically important.

Fish Utilization

There has been an increased understanding that shell bottom provides critical fisheries habitat not only for oysters, but also for recreationally and commercially important finfish, other mollusks, and crustaceans. The ecological functions of oyster reefs related to oyster production are well known and accepted (Coen

et al. 1999). These functions include aggregation of spawning stock, chemical cues for successful spat settlement, and refuge from predators and siltation. Oysters have also been described as "ecosystem engineers that create biogenic reef habitat important to estuarine biodiversity, benthic-pelagic coupling, and fishery production."[4] (Lenihan and Peterson 1998).

Data quantifying fish use of habitats vary from presence/absence and numerical abundance, to actual fish production value. In North Carolina, 18 fishery species have been documented utilizing both natural and restored oyster reefs in Pamlico Sound, including Atlantic croaker, southern flounder, Spanish mackerel, spotted seatrout, weakfish, American eel, and black sea bass (Lenihan et al. 2001). Numerical abundance and production compared to other habitats provides additional information on the importance of habitat for fish. The species found most abundantly on oyster reefs compared to adjacent soft bottom were silver perch, sheepshead, pigfish, pinfish, toadfish, and Atlantic croaker. Southern flounder was collected on both oyster reefs and adjacent soft bottom areas, while bluefish and Atlantic menhaden were not collected near oyster reefs (Lenihan et al. 2001).

Several studies have found higher abundance and diversity of fish on shell bottom than adjacent soft bottom, particularly pinfish, blue crabs, and grass shrimp (Harding and Mann 1999; Posey et al. 1999; Lenihan et al. 2001). A study in Back Sound also found that crabs were more abundant on shell bottom than restored SAV beds (Elis et al. 1996). Breitburg (1998) concluded that the importance of shell bottom to highly mobile species is very likely underestimated, partially due to the difficulty in sampling oyster beds.

Peterson et al. (2003) estimated the amount of fish production that shell bottom provides in addition to adjacent soft bottom habitats. Using results from numerous studies, they compared the density of fish at different life stages on oyster reefs and adjacent soft bottom habitats. The published growth rates of species were then used to determine the amount of production gained from shell bottom. The species were separated into recruitment-enhanced, growth-enhanced, and not enhanced groups. Recruitment-enhanced species are those having early life stages showing almost exclusive association with shell bottom. For other species with higher abundance in shell bottom, diet and life history studies were used to determine the fraction of their production associated with the consumption of shell bottom-enhanced species. Species consuming relatively more shell bottom-enhanced species were classified as growth-enhanced. Analysis of the studies revealed that every $10m^2$ of newly constructed oyster reef in the southeast United States is expected to yield a benefit of an additional 2.6 kg of fish production per year for the lifetime of the reef (Peterson et al. 2003).[5]

Fish that utilize shell bottom can be classified into three categories: resident, transient, and facultative (Lowery and Paynter 2002; Coen et al. 1999). Resident species live on shell bottom and depend on it as their primary habitat. Transient species are wide-ranging species that use shell bottom for refuge and forage along with other habitats. Facultative species depend on shell bottom for food, but utilize other habitats with vertical relief or shelter sites.

At least seven fish species have been identified as resident species—naked goby, striped blenny, feather blenny, freckled blenny, skilletfish, and oyster toadfish (Coen et al. 1999, Lowery and Paynter 2002). These species were also considered recruitment-enhanced by Peterson et al. (2003). Resident fish are

[4] Benthic-pelagic coupling refers to the transfer of production from the oyster beds to the mobile species foraging on the beds (Lenihan and Peterson 1998), benefiting both estuarine and ocean fisheries. It also refers to the transfer of phytoplankton production and other fine particulates to the bottom.

[5] For individual species, the amount of additional production ranged from 0.08 (spottail pinfish) - 158.80 (bay anchovy) fish/$10m^2$. Of the 53 species of fish and shellfish for which data was available, ten were recruitment-enhanced and ten were growth-enhanced. About half of the twenty shell bottom-enhanced species were fishery species (sheepshead, black sea bass, gray snapper, white perch, gag, pigfish, southern flounder, and tautog). The recruitment-enhanced species included stone crabs, sheepshead, blennies/gobies, skilletfish, gray snapper, gag, toadfish, and tautog. Growth enhanced species included bay anchovies, black sea bass, sheepshead minnow, spottail pinfish, silversides, white perch, pigfish, and southern flounder.

important prey for transient and facultative predator species (Coen et al. 1999). For example, Breitburg (1998) found high densities of juvenile striped bass (15.4 individuals/m^2 of reef surface) aggregating near the reef surface feeding on naked goby larvae congregated on the down-current side of the reef. Other common predator species sampled on oyster reefs in North Carolina are red and black drum, Atlantic croaker, sheepshead, weakfish, spotted seatrout, summer and southern flounder, blue crab, and oyster toadfish. Of these species however, only sheepshead, southern flounder, and oyster toadfish were considered shell bottom-enhanced by Peterson et al. (2003). Production of black drum, Atlantic croaker, blue crab, and summer flounder were classified as not enhanced by shell bottom. Oyster reefs in higher salinity waters are critical habitat for predators such as juvenile gag, snappers (*Lutjanus* spp.) and stone crab (Wenner et al. 1996; Peterson et al. 2003).

There is some variation in fish use among salinity gradients as well. Oyster reefs in higher salinity waters tend to support a greater number of associated species than reefs in lower salinity waters (Sandifer et al. 1980). Studies summarized by Coen et al. (1999), which included work in North Carolina, identified 72 facultative, resident and transient fish species in close proximity to oyster reefs. The ASMFC-managed species categorized as transient and also important to North Carolina's coastal fisheries are American eel, Atlantic croaker, Atlantic menhaden, black sea bass, bluefish, red drum, spot, striped bass, summer flounder, tautog, and weakfish. Only black sea bass and tautog were considered shell-bottom enhanced by Peterson et al. (2003).

A partial list of macrofaunal species observed in collections from oyster habitat is provided in Table 3.2. Those species that use shell bottom as spawning and/or nursery areas are identified, as are those species that forage on shell bottom habitat and/or use it as a refuge (SAFMC 1998a; Lenihan et al. 1998; Coen et al. 1999; Grabowski et al. 2000). More than 30 species are listed in Table 3.2, and there are many more not listed, emphasizing the importance of shell bottom as fisheries habitat.

Refuge

The complex three-dimensional shell habitats provide food, refuge, and attachment areas for larval, juvenile, adult, and spawning finfish, crustaceans and mollusks (Arve 1960; Wells 1961; MacKenzie 1983; Meyer et al. 1996; Zimmerman et al. 1989; Breitburg 1998; Lenihan et al. 1998; Coen et al. 1999; Harding and Mann 1999). Oyster reefs provide more area for attachment of oysters and other sessile organisms. More habitat niches occur in oyster reefs than on the surrounding flat or soft bottom habitats. Bartol and Mann (1999) found the quality and quantity of interstitial spaces (spaces between the shells within the shell matrix) to be critical to recruiting oysters, as well as to the survival of other oyster reef species. Survival was greater in the interstitial spaces than at the reef surface.

The crevices in shell bottom provide refuge for small, slow-moving macrofauna, such as polychaete worms, blue crabs, hard clams, amphipods and other species (Zimmerman et al. 1989; SAFMC 1998a). Mud crabs utilize shell bottom as refuge from oyster toadfish, blue crabs and wading birds (Meyer 1994). While crabs utilize the shell structure to hide from predators in the day, sampling found that they migrate to the open mud flats at night to feed (Grabowski et al. 2000). Competition for shell bottom habitat as refuge is greatest within similar size categories of fauna (Coen et al. 1999).

Since shell bottom substrates provide significant protection from predators for adult and juvenile hard clams, it has been designated an Essential Fish Habitat by the SAFMC for that species (SAFMC 1998a). Peterson et al. (1995) reported that young clams survived better in shell bottom than open soft bottom areas. The DMF specifically manages some intertidal oyster cultch planting sites in the southern coastal area to take advantage of this hard clam–oyster shell relationship. After oysters are harvested off the planted site, the areas are opened specifically for clam harvest by hand gears. Fishermen dig under the cultch to take high concentrations of hard clams that recruited under the oyster shell. Once the clam harvest is over, the areas are re-planted with cultch, and the two-year cycle begins again.

[2] Existing commercial or recreational fishery. Fishery and non-fishery species are also important as prey

* Status from unpublished SAFMC document ("Briefing Material for SAFMC, December 2002 meeting")

Where assigned functions are not listed for a species, this does not mean there are none, only that documentation for that specific function is unavailable. **Bolded** species indicate some preference for shell bottom habitat over other habitats documented in the text. **RE**=recruitment enhanced; **GE**=growth enhanced; **NE**=Not enhanced. Peterson et al. (2003).

Subtidal oyster reefs may be relatively more important to commercially important finfish than intertidal reefs, because subtidal reefs often provide the only structured habitat in submerged areas (Grabowski et al. 2000). In contrast, intertidal reefs are often surrounded by other structured habitats, such as salt marshes and SAV beds. From southeastern North Carolina to northern Florida, where SAV does not

occur, shell bottom represents the dominant structural habitat in the mid-intertidal to shallow subtidal waters (Posey et al. 1999). In other intertidal estuaries in North Carolina where little or no SAV is present, shell bottom also provides critical structural refuge, along with salt marsh (Eggleston et al. 1998).

Spawning

Resident species, such as gobies (seaboard and green), the longhorn sculpin, Atlantic midshipman, and northern pipefish depend on shell bottom as breeding habitat (Hardy 1978a 1978b; Johnson 1978; Coen et al. 1999). Other species documented to spawn on shell bottom include the oyster toadfish, mummichog, sheepshead minnow, eastern oyster, pink shrimp, grass shrimp, and hard clams (NOAA 2001). Toadfish attach their eggs to the underside of oyster shells, whereas gobies, blennies, and skilletfish place their eggs in recently dead oyster shell (Coen et al. 1999). Well-developed oyster reefs with clean oyster shells in a variety of sizes were shown to accommodate reproduction by the greatest densities of all resident species (Breitburg 1998).

Nursery

Shell bottom protects oyster spat and other juvenile bivalves, finfish and crustaceans from predators. Juvenile clams, in particular, settle in shell substrate for the protection it provides (Wells 1957; MacKenzie 1977; Peterson 1982; DMF 2001b). The nursery area function of shell bottom was demonstrated by Eggleston et al. (1998) who found that juvenile blue crabs and grass shrimp were equally abundant on shell bottom and SAV in Back Sound, North Carolina. Twelve of the eighteen mobile and economically important coastal fisheries species sampled by Lenihan et al. (2001) on natural and restored oyster reefs in Pamlico Sound were juveniles.

In a study where shell structure was added to mud flat reefs, juvenile fish abundance increased on the augmented reefs compared to surrounding soft bottom (Grabowski et al. 2000). The study also found that this initial increase was higher than increases that occurred when SAV and/or salt marsh were added in the same area. The ASMFC considers shell bottom as important nursery habitat for juvenile fish such as sheepshead, gag, snappers, stone and blue crabs, and penaeid shrimps (Lowery and Paynter 2002). An analysis by Peterson et al. (2003) confirmed that sheepshead, gag, and stone crab were recruitment enhanced, as well as many non-fishery species, including anchovies, blennies, gobies, oyster toadfish, skilletfish.

Foraging

Shell bottom provides important foraging area for a variety of aquatic organisms. Fish, shrimp and crabs forage on the worms, algae, crustaceans, mollusks, and other invertebrates present on and in shell bottom habitat. Concentrations of prey organisms among the shell attract both specialized and opportunistic predators. Eggs from oysters and other organisms, and larvae from the oyster shell bottom community are eaten by protozoans, jellyfishes, ctenophores, hydroids, worms, mollusks, adult and larval crustaceans, and fishes (Loosanoff 1965). Blue crabs forage heavily on oyster reefs (Menzel and Hopkins 1955; Krantz and Chamberlin 1978; Mann and Harding 1997). Stomach contents of common finfish predators sampled near shell bottom in Middle Marsh, North Carolina, included fish, shrimp, tanaids, amphipods, isopods, polychaetes, bivalves, gastropods, and tunicates, as well as plant, algal and detrital material (Grabowski et al. 2000).

Grabowski et al. (2000) calculated an index of reef affinity (association) for fish species and analyzed the relative proportion of stomach contents originating from oyster reef verses non-reef habitats. Results showed:

- Pigfish and pinfish foraged more on reefs (amphipods, bivalves, gastropods and polychaetes).
- The ubiquitous spot foraged on both reef and non-reef habitats.
- Gulf and southern flounder foraged on species slightly more common on reefs.

- Blacktip sharks, spotted seatrout, and bluefish exhibited a feeding preference for oyster reef prey (fish, shrimp and crabs).
- Red drum foraged slightly more off reefs.
- Blacknose sharks rarely foraged on reef habitats.

The growth-enhanced species/groups identified in Peterson et al. (2003) included sheepshead minnow, silversides, pigfish, southern flounder, and black sea bass. These results differ somewhat from those of Grabowski et al. (2000). The discrepancies between Peterson et al. (2003) and Grabowski et al. (2000) could be due to regional differences in fish habitat use, or other unknown factors. Sheepshead also have an affinity for slow or sessile invertebrates found abundantly on shell bottom (Pattilo et al. 1997).

Corridor and Connectivity

Shell bottom serves as a nearshore corridor to other fish habitats, such as salt marsh and SAV for finfish and crustaceans; therefore, it plays a significant ecological role in landscape-level processes (Coen et al. 1999; Micheli and Peterson 1999). Vicinity (isolation) and connectivity of intertidal oyster reefs to other fish habitats, especially SAV, are two factors that affect fish utilization of shell bottom. For example, connectivity of oyster reefs to SAV enhanced blue crab predation, whereas isolation of oyster reefs enhanced hard clam survivorship (Micheli and Peterson 1999). In Middle Marsh, North Carolina, gag, gray snapper, and spottail pinfish preferred shell bottom habitat adjacent to SAV beds (Grabowski et al. 2000), allowing access to both refuge and prey.

3.3. STATUS AND TRENDS

Status of shell bottom habitat

During the colonial period in the mid-Atlantic, oyster reefs grew so extensively that they were considered to be a hazard to navigation (Newell 1988). U.S. Navy Lieutenant Francis Winslow documented the historical distribution of oyster beds in North Carolina in 1886-1887. Winslow (1889) surveyed 1,325,419 acres in 17 areas extending from Croatan and Roanoke sounds west to the lower Pamlico and south to the eastern edge of Bogue Sound, and located 8,328 acres of public and private oyster beds (0.6% of the bottom). Allowing for expansion of oyster beds, Winslow et al. (1889) also located 20,554 acres of "public oyster grounds." In the North River estuary of Carteret County, Winslow (1889) found 243 acres of natural oyster beds, 310 acres of private beds, and about 600 acres of additional public oyster grounds. In the same general area during the 1990s, the DMF Shellfish Habitat and Abundance Mapping Program estimated there were 445 acres of shell bottom. The DMF mapping program includes scattered, individual shellfish and shellfish clusters as shell bottom, while Winslow (1889) only counted shellfish clusters, making comparisons difficult. DMF's Shellfish Mapping data on shellfish cluster abundance are therefore more inclusive than the Winslow data. However, DMF mapping data could be analyzed by shellfish density to approximate changes in abundance.

Other studies suggest that viable oyster beds have been displaced downstream roughly 10-15 miles in the Pungo, Pamlico, and Neuse rivers since the late 1940s (Jones and Sholar 1981; Steel 1991). The DMF's Shellfish Habitat and Abundance Mapping Program has not yet mapped these estuarine systems, as mapping existing shell bottom for protection is prioritized. Current priority for the Shellfish Mapping Program is the lower Neuse River, followed by areas to the north. Because this detailed mapping process is time consuming, *change analysis would need to be limited to a subset of priority areas. Priorities should be based on a combination of functional significance, economic value, and the magnitude of growth and development threatening the area.*

The status of shell bottom can also be evaluated using area-specific oyster harvest and effort data, fishery-independent sampling data, or site-specific studies on reproduction, growth, and recruitment. Based on harvest data, North Carolina oyster stocks were in a state of decline for most of the 20th century (DMF

2001a). North Carolina's oyster landings have generally declined from a peak coinciding with the introduction of the oyster dredge in 1889 to today's low harvest (Figure 3.1). Data on landings by gear type indicate that, between 1887 and 1960, most oysters were harvested by dredge when compared to all hand methods (DMF 2001a). Chestnut (1955) reported that 90% of the oysters landed in North Carolina came from dredging operations in the Pamlico Sound. These harvesting practices were the primary cause of initial degradation and loss of shell bottom habitat in the Pamlico Sound area (DMF 2001a; Jackson et al. 2001).

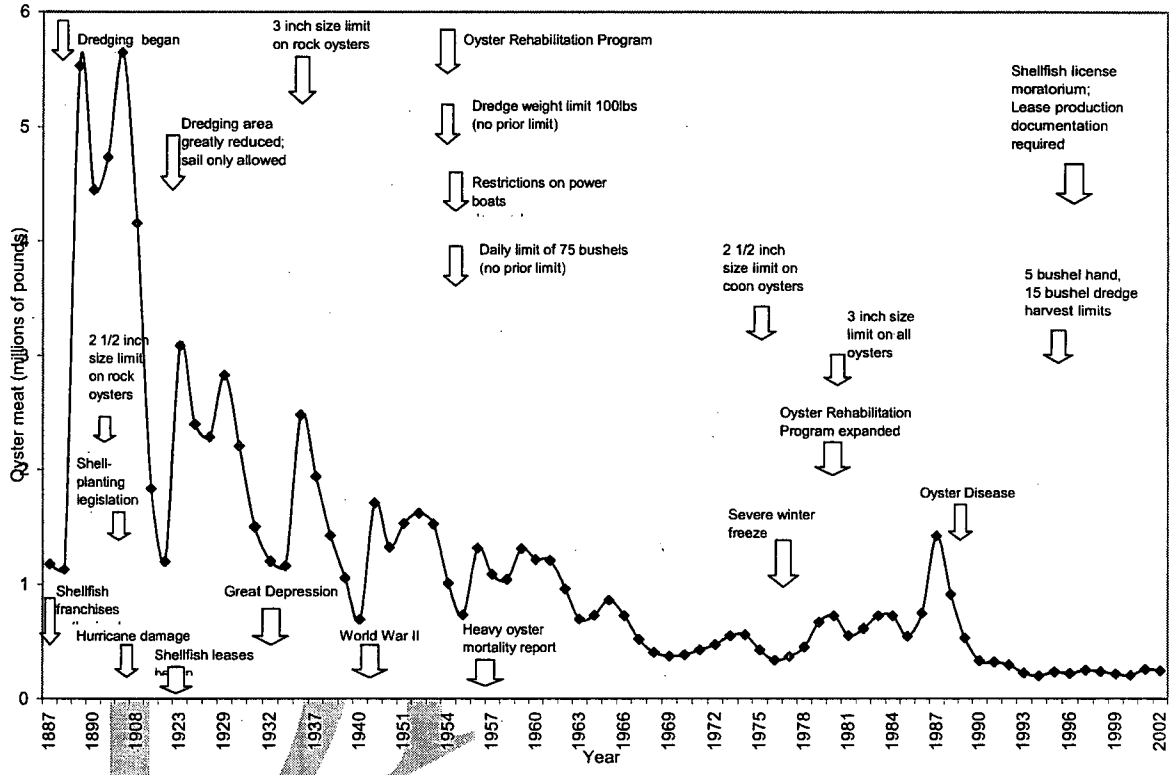

Figure 3.1. Factors affecting the North Carolina oyster fishery 1887-1999. *[Source: DMF 2001a]*

Since 1991, oyster stocks and harvests from Pamlico Sound have collapsed due to high mortalities from disease and low spawning stock biomass (DMF 2001a). Oyster dredges are still used in the fishery in Pamlico Sound and its tributaries, but are not permitted in the southern portion of the state. Since 1994, oyster dredge fishery landings have accounted for only 1% to about 21% of the annual oyster catch. Landings data indicate that, since 1997, oyster harvest has remained fairly constant at around 50 pounds of oyster meat landed per oyster dredging trip, while the number of trips, although generally increasing, has fluctuated between 3 and 943 (Figure 3.2).

Oyster populations in the southern portion of the coast have suffered only moderately from disease and, due to a prohibition on the use of mechanical oyster harvest methods south of Pamlico Sound, these populations have not been impacted by those methods (DMF, unpub. data). The harvest of oysters in this area is primarily limited by availability of open areas, since harvest closures have increased over time due to pollution, fishing effort is high, and oyster beds are easily accessible. In North Carolina coastal waters overall, cumulative and secondary effects from severe disease infestations, coupled with continued

decline in suitable habitat, have seriously impacted oyster stocks.[6]

Average oyster spatfall in the Pamlico Sound area for the 1989–1999 period was less than half the value for the 1979–1988 period (DMF 2001a) (Figure 3.3). Unpublished DMF spatfall data for cultch planting sites over the past 24 years indicate a decline in maximum spatfall relative to similar surveys reported by Chestnut (1955). Some researchers suspect that oysters are becoming spawner-limited, while others attribute the decline to stress and mortality from infectious diseases that affect primarily larger, more fecund (egg-producing) adults (Choi et al. 1994; DMF 2001a; Lenihan et al. 1999), or to physical damage from dredging (Marshall et al. 1999). However, there has been no reported decline in spatfall in the southern coastal area of North Carolina (R. Carpenter, DMF, pers. com., 2002).

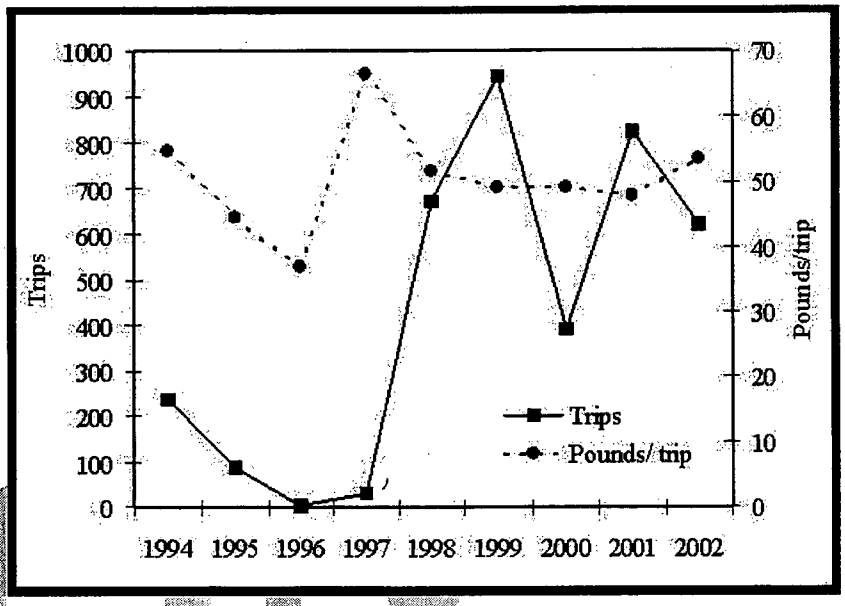

Figure 3.2. Oyster dredge effort by trips in North Carolina and pounds of oyster meat landed per trip during 1994-2000 (DMF, unpub. data).

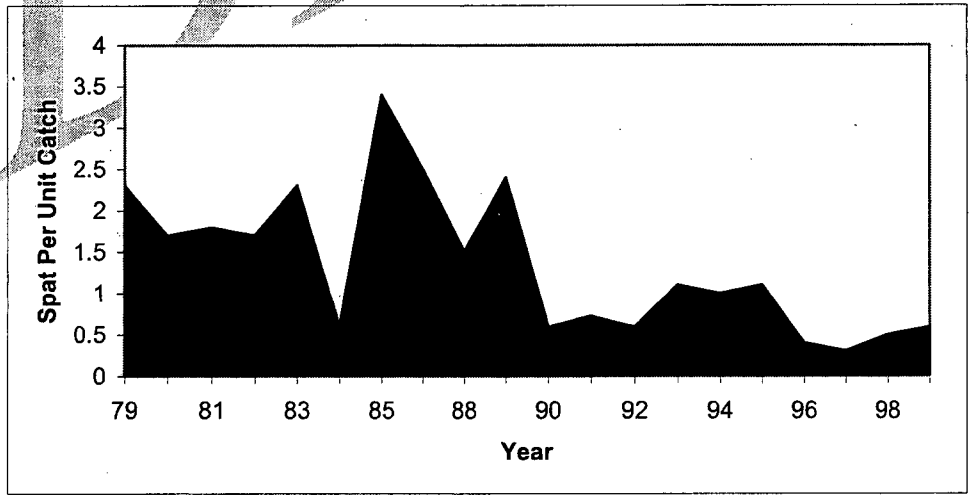

Figure 3.3. Pamlico Sound area average oyster spatfall per unit catch, 1978–1999 (DMF, unpub. data).

[6] Fishing gear and disease impacts are given a more thorough discussion in the Section 3.4 (Threats and Management Needs).

Status of associated fishery stocks

Based on the link between fishery species and shell bottom established in Section 3.2, some inferences can be made using the status and trends of fishery species that are highly dependent on shell bottom habitat (bolded species in Table 3.2). However, utility of the inferences is severely limited because the majority of shell bottom loss occurred before detailed fishery statistics were collected (prior to 1972). Recent fishery statistics provide a benchmark for future analysis, especially trip ticket data collected since 1994.

Of at least twenty-eight species (other than oysters) showing some preference for shell bottom (Table 3.2) habitat, ten species, comprising at least thirteen stocks, were evaluated for fishery status. Of the eleven stocks whose status was known, three were designated Overfished (25%), two were Concern (17%), one was recovering (8%), and five were viable (50%) (Figure 3.4). Specifically, the central-southern stock of striped bass, southern flounder, and sheepshead are classified as Overfished; blue crab and black sea bass south of Cape Hatteras are classified as Concern, and red drum is classified as Recovering (DMF 2003a; SAFMC 2002). Viable species include ocean and Albemarle Sound stocks of striped bass, black sea bass north of Cape Hatteras, spotted seatrout, shrimp, and gag. The stock status of hard clams, stone crabs, black drum and other shell bottom-associated fishery species is unknown.

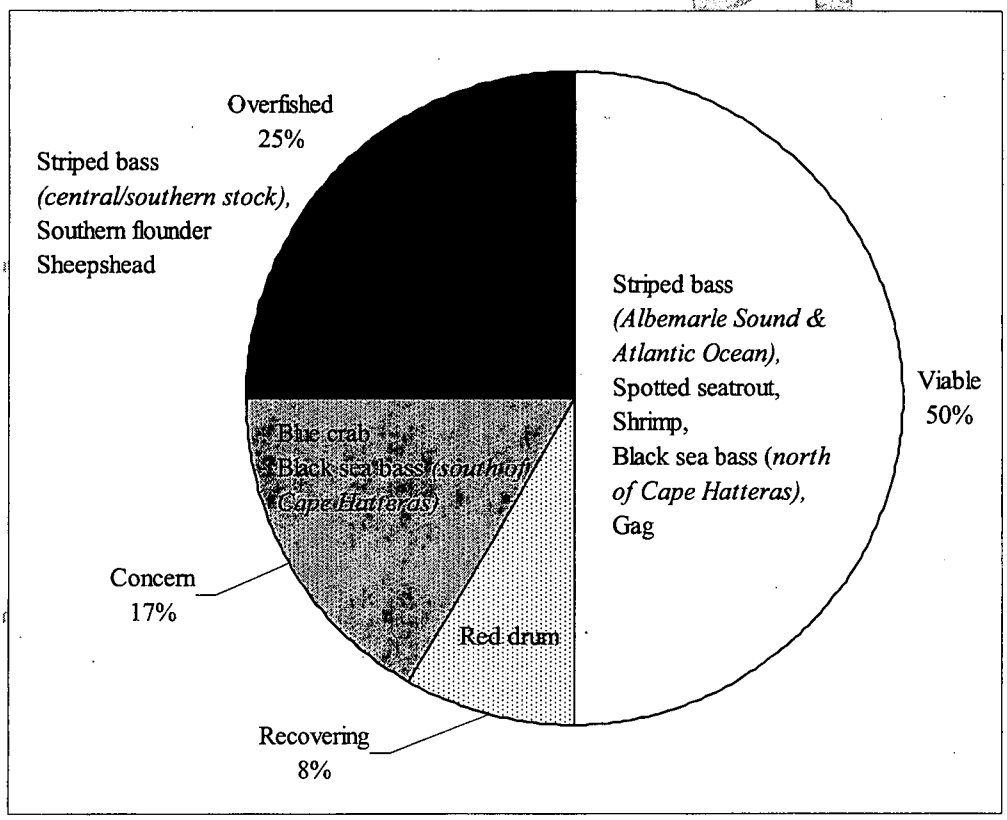

Figure 3.4. Percent of fish stocks showing some preference for shell bottom habitat that were classified as Overfished, Concern, Recovering, or Viable in the 2003 DMF Stock Status Report.

Unviable stock status could be attributed to a variety of causes ranging from habit loss, disease, and overfishing, to annual variation in climatic conditions. Compounding this uncertainty is the fact that

status of shell bottom-associated species, such as hard clams, sheepshead, and black drum, is currently unknown. *More information is needed on the status of hard clams, sheepshead, black drum, and resident non-fishery species (i.e., oyster toadfish) as indicators of shell bottom conditions. Due to the limitations of using fisheries-dependent data (landings data) to indicate stock trends, fisheries independent-data should be collected for these species to develop independent indices.* Status and trends of hard clams are currently being evaluated by DMF. The capacity of shell bottom habitat to affect water quality and overall community structure would probably be the best indicator of status and trends in shell bottom habitat. *However, before this function could be used as an indicator, research is needed on the critical amount and quality of living and dead shell bottom in a water body below which significant changes in biotic community structure occur.*

Shell bottom restoration

State efforts to restore oyster habitat and enhance oyster fishery production began around the turn of the century (Marshall et al. 1999). These efforts relied mostly on planting a variety of natural cultch, including oyster, clam, and scallop shells, and more recently, limestone marl. Experimental oyster cultch plantings began in 1900, and state-sponsored cultch planting began in 1915 (Marshall et al. 1999). Between 1915 and 1934, a total of 1,856,379 bushels of shells and seed oysters were planted in North Carolina's estuaries. The Oyster Rehabilitation Program officially began in 1947 and resulted in planting 838,088 bushels of shell and 350,734 bushels of seed oysters over its first 10 years. Since 1970, North Carolina has relied almost exclusively on cultch planting as a means of enhancing oyster production (Figure 3.5). From 1958 to 1994, 12,475,000 bushels of shell material were planted, for an annual average of 337,162 bushels (Marshall et al. 1999). Over the entire period of cultch planting from 1915-1994, there has been a total of about 15 million bushels of oysters planted in North Carolina waters. This volume of shells would contain the equivalent of 4.5 billion 2-inch oyster shells. Using a minimum 30% area coverage (100 2-inch shells/m^2) as defining shell bottom, the volume of shell cultch planted from 1915-1994 could cover as much as 11,120 acres (45,000,000 m^2). However, this is an overestimate of actual shell bottom area gained, because the shell plantings consist of piles of variable thickness rather than a single uniform layer. Also, many of the cultch areas are replanted due to flattening by waves and/or commercial harvesting. Despite these planting efforts, the oyster harvest continued to decline (Marshall et al. 1999).

Similar to natural shell bottom, restored oyster reefs provide bottom habitat for economically important species (Lenihan et al. 1998; Breitburg 1998; Coen et al. 1999; Harding and Mann 1999; Grabowski et al. 2000; Lenihan et al. 2001; Peterson et al. 2003). Recent studies have examined the habitat value of constructed oyster reefs compared to natural oyster reefs. The researchers found that landscape characteristics seemed to influence fish species' relative abundance (i.e., connectivity with SAV and/or salt marsh). Fish abundance was significantly greater on restored oyster reefs adjacent to SAV than on mud flat and/or salt marsh restored reefs (Grabowski et al. 2000). Restored intertidal oyster reefs produced significantly more economically valuable oysters ($95.68/10 m^2) than estimates of oyster production on subtidal reefs ($11.61/10 m^2). The value of legal oysters present on mud flat reefs ($129.38/10 m^2) exceeded that for oysters on salt marsh ($50.50/10 m^2) or SAV restored reefs ($24.25/10 m^2). They estimated that the long-term value of commercial fisheries landings from restored reefs was greater than the oyster harvest for both intertidal and subtidal shell bottoms.

The habitat benefits of cultch plantings may only be limited or temporary if the shell bottom is removed or damaged by towed fishing gears or other harvesting gears (Marshall et al. 1999). Cultch plantings in the southern areas (Onslow, Pender and New Hanover counties) are frequently replanted after harvesting to replenish cultch material for recruitment (Marshall et al. 1999). It generally takes about 3-4 years before oysters on planted sites reach harvestable size in the Pamlico Sound system, while oysters reach the minimum legal size of 3 inches in about two years in the southern coastal area. Faster growth in this area is due to higher rates of water exchange caused by greater tidal flow than in most of Pamlico Sound. The increased flow brings in more food and prevents oxygen depletion problems.

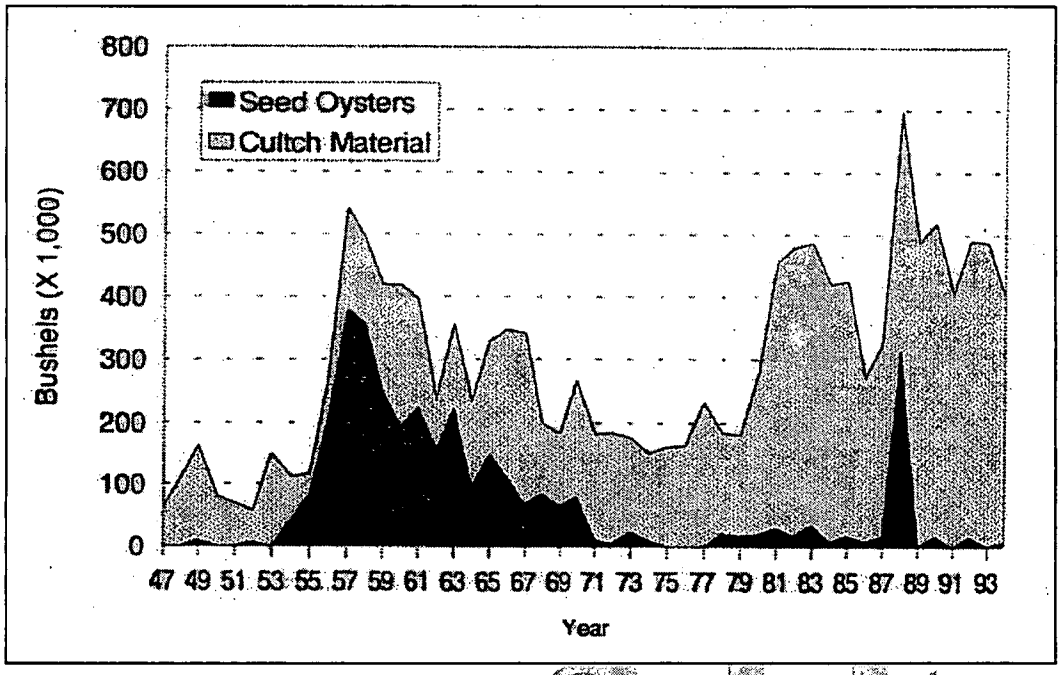

Figure 3.5. North Carolina oyster rehabilitation activities for 1947 – 1994. (from Marshall et al. 1999. The peak in 1988 was due to special state disaster funding during the red tide of 1987-88. Data are stacked to show cumulative total.)

The majority of cultch planting sites during 1990-1994 were in Pamlico Sound, lower Neuse River and lower Pamlico River (Marshall et al. 1999). The same general areas were also planted in 2001 and 2002 (Maps 3.4a-b). Most of the recent (2001-2002) oyster restoration effort has been conducted in large bays around Pamlico Sound and in smaller tributaries of other estuaries (Maps 3.4a-b). The majority of these sites are "new" plantings on basically barren sediment (Marshall et al. 1999). Criteria for site selection include suitable sediment types, currents, protection from storm damage, historical productivity, salinity patterns, and existing shellfish concentrations. The presence of bottom disturbing fisheries, such as trawling, hydraulic clamming, and long haul seining is also considered. Recommended sites for cultch plantings are often narrow bands of mixed sand and mud sediment between shallow, hard, nearshore sediment and soft offshore sediment. In deep water, large oyster mounds are constructed to increase recruitment and reduce effects of low oxygen on the bottom. The planting sites are monitored for oyster recruitment and survival over a period of three years (DMF 2001a). Using vessels currently in operation, cultch can be planted in water as shallow as two feet (Marshall et al. 1999). Since the early 1980s, the DMF has concentrated primarily on cultch plantings and small-scale, high quality seed transplanting activities, also referred to as the "relay program." In the relay program, oysters are removed from dense oyster populations in prohibited areas and relocated to open harvest areas with depleted resources. The Relay Program is very small and concentrated in the south, where there is very little effect on the seed source areas (M. Street, DMF, pers. com., 2003).

The primary purpose of the DMF cultch-planting program since it began has been oyster fishery enhancement. The DMF enhancement efforts have also been directed at providing stable long-term oyster habitat because research in recent years shows that oyster reefs have important ecological and economic value as coastal fisheries habitat. This broadening of focus for the protection/restoration program has occurred since the late 1990s. As of 2001, there were five constructed/artificial reef sanctuaries in North Carolina located in Bogue Sound, West Bay (Tump Island), Deep Cove (Swan

Quarter), Croatan Sound, and behind Hatteras Village (DMF 2001a). Work is currently underway to enhance several existing restoration sites and create additional sites. These areas are no-take, no-disturbance sanctuaries (C. Hardy, DMF, pers. com., 2002). In other states, sanctuaries are a major component of restoration efforts (CBP 2000). *Creation of additional "no take" subtidal oyster sanctuaries has been recommended by Frankenberg (1995), the Chesapeake Research Consortium (1999), and Lenihan et al. (1998).*

There are multiple ecological benefits of constructed and natural oyster sanctuaries, including the following (Breitburg et al. 2000):

- Protection of brood stock,
- Enhancement of oyster populations in surrounding harvested areas through larval dispersion,
- Protection of disease-resistant oysters, improving the genetic pool for disease resistance, and
- Protection of associated fisheries and other organisms from predation through development and maintenance of maximum vertical relief and structural complexity.

The first true oyster reef restoration project in North Carolina occurred in 1992-1993 when 13 acres of oyster producing habitat were created as mitigation for the loss of 16 acres of estuarine bottoms and 1.5 acres of wetlands in Roanoke Sound (Marshall et al. 1999). The DMF is monitoring the site as part of a mitigation agreement with the U.S. Army Corps of Engineers (COE). More recently, the DMF has performed mitigation projects for the North Carolina Department of Transportation, and additional projects creating more than 70 acres of shell bottom are planned with the COE (Marshall et al. 1999). Research is continuing on how to better construct these sites to provide effective oyster habitat. *However, in the Pamlico Sound region where spatfall continues to decline (Marshall et al. 1999), more planting and longer protection of sites may be required to achieve the same results as previous restoration efforts. Restoration efforts must use knowledge of larval availability in order to be most effective.* In southern waters, the amount of shell habitat is generally stable, but the amount of harvestable area is decreasing as closures increase because of contamination from storm water runoff (R. Carpenter, DMF, pers. com., 2002).

Restoration of shell bottom is also undertaken by non-profit groups. One such project has been initiated in Pamlico Sound by The Nature Conservancy, in cooperation with NOAA's Community-Based Restoration Program and several partners. The goal of the Project is to enhance the biological diversity of Pamlico Sound by establishing a self-sustaining complex of living oyster reefs throughout the estuary. The Conservancy has enlisted the cooperation of marine scientists to ensure the most up-to-date techniques for siting, construction, and management are used. Some criteria for site selection include depth, salinity, shellfishing-prohibited status, disease-resistant salinities, reef footprints, presence of larvae, and proximity to SAV, salt marsh, fish nursery areas, or Military Protected Areas. States and territories containing anadromous, estuarine, and marine species are eligible to compete for Community-Based Restoration grants typically ranging from $25,000 to $75,000.[7] *As the number of oyster restoration projects grows, the need for an overall strategy for shell bottom restoration also increases.*

Any expansions of the current restoration/enhancement effort will require additional sources and funding for oyster cultch or limestone marl. Funding for the acquisition of cultch material was drastically cut in DMF's 1990 budget. As a result, the DMF currently has more planting capability than available cultch material. *Funding for acquisition of cultch material must be increased to more efficiently use the existing planting capabilities of DMF.* The DMF began a voluntary shell-recycling program in 2004 using local coordinators to collect discarded shells from individuals and businesses. The shells are later transferred to stockpile facilities before being planted in new or expanding oyster sanctuaries. The amount of cultch volunteered could somewhat offset the amount of funding needed for additional cultch material.

[7] For information on guidelines and requirements for the grants, visit <http://www.conserveonline.org>, or the NOAA Fisheries Restoration Center at <http://www.nmfs.noaa.gov/habitat/restoration>.

However, the amount of cultch volunteered is probably secondary to the public awareness gained from a shell-recycling program.

3.4. THREATS AND MANAGEMENT NEEDS

Although shell bottom consists of both living and non-living shell material, annual recruitment of live shellfish is needed to sustain the supply of shell material and three-dimensional structure of oyster reefs. Therefore, any activities that directly remove or destroy live shellfish, or indirectly prevent or slow growth and survival, are threats to shell bottom habitat. Mollusks that contribute shell material include oysters, hard clams, bay scallops, as well as many non-fishery species. Since oysters are the dominant contributor to shell bottom, the threats discussed below focus primarily on oyster reefs.

Physical threats

Mobile bottom disturbing fishing gear

Mechanical fishing gear includes any gear that is towed or run by engine power including dredges, hydraulic clam dredges, clam kicker, bottom trawls, or patent tongs. Over-harvesting and habitat destruction from oyster dredging was the initial cause for the large-scale decline in oyster resources from approximately the late 1800s to the mid-1900s, particularly in the northern portion of North Carolina. Although other factors had contributed to the decline in the oyster fishery, tonging and dredging had the greatest impact on the physical structure of the reefs (Hargis and Haven 1988; Rothschild et al. 1994). One full season of oyster dredge harvesting effort reduced the mean height of restored subtidal oyster reefs by 30% (DeAlteris et al. 1999; Lenihan and Peterson 1998). Because of this high removal rate, DMF has added shell to heavily fished subtidal areas approximately every 3 to 4 years to maintain the fishery (Frankenberg 1995).

Oyster dredges reduce the vertical relief of subtidal oyster reefs resulting in several negative habitat impacts (Lenihan and Peterson 1998; Lenihan et al. 1999):

- Scattering of shell and oysters into less suitable substrates.
- Destabilization of the reef structure, which increases vulnerability to damage by future storms.
- Removal of live and dead oysters and portions of the upper layers of the shell which:
  - Decreases potential number of spawning adults (spawning stock biomass).
  - Decreases area available for settlement by oyster larvae.
  - Subjects newly settled oysters to lower oxygen and increased sediment due to lower depth in water column.
- Reduction in the small spaces within the oyster reef that function as refuge and foraging areas for juvenile fish.
- Decreased resistance to disease [8].

Between the 1970s-1990s, the negative impact of the oyster dredge on shell habitat was recognized, and areas were designated where all mechanical methods for shellfish harvest were prohibited (Maps 3.5a-c). These mechanical methods include towed dredges, hydraulic dredges, patent tongs, rakes powered by engine, and clam trawling ("kicking" clams with vessel propellers so they are caught in a small trawl).

Trawling and dredging, and all mechanical shellfish harvest methods are prohibited in MFC designated Primary Nursery Areas (PNAs), and trawling is prohibited in permanent Secondary Nursery Areas and Shellfish Management Areas [MFC rules 15A NCAC 03N .0104 and .0105, 03J .0103], protecting shell bottom in these shallow water areas. The rules defining nursery areas has been in effect since 1977. Maps 3.5a-c depict the areas where trawling and dredging are not allowed by MFC rules (including PNAs, mechanical harvest prohibited areas, SAV beds). However, trawling over bottom in tributaries of

[8] see discussion under "Disease"

Pamlico Sound, where productive oyster beds once existed, continues, possibly preventing oysters from reestablishing in part of their historic range (Frankenberg 1995). *Construction of oyster sanctuaries in locations of historic abundance and restriction of trawling over restored shell bottom is necessary to restore shell bottom in these northern subtidal areas.* There are also areas where trawling is prohibited, but oyster dredging is not. *Oyster dredging in these areas should also be prohibited.*

Use of oyster dredges has been severely limited by the MFC in recent years due to habitat impacts. However, the historic subtidal oyster beds have not recovered (Lenihan and Peterson 1998). Degraded water quality, partially due to reduced filtering by oysters after stocks were greatly reduced, and increased disease occurrence from environmental stress is thought to have prevented full recovery (Jackson et al. 2001; Lenihan and Micheli 2000). Approximately 222,224 acres of shellfish bottom in the Neuse, Pamlico, Tar-Pamlico, and Albemarle MUs are open to oyster dredging at least temporarily. Forty-five percent of this area is within the Pamlico Sound MU. Oyster dredging is prohibited in the southern portion of the state's estuarine waters because the majority of shell bottom resources south of Pamlico Sound are intertidal.

Considering the average number of oyster dredge trips reported from 1994 through 2000, there has been approximately 1 trip/year for every 380 acres of the shellfish mapping study area open to dredging. The total amount of damage to shell bottom depends on the effect of each trip and the relative amount of shell bottom within the mapping area. *One of the recommendations of the North Carolina Oyster Management Plan is the adoption of criteria to designate additional areas where mechanical harvest methods are prohibited (DMF 2001a).* The new additions are intended to protect shellfish beds in potential hand harvest areas.

Trawling for shrimp, crabs, and finfish, and long haul seining and dredging for crabs have similar types of habitat impacts as oyster dredges, but at reduced levels of disturbance (DMF 2001a). The weight and movement of trawl doors or chain towed across the seafloor can disrupt the structure of the oyster mound, removing the upper layers of shells or scattering oysters (DMF 2001a). Long haul seines dragged through shell bottom can also damage oyster mound structures by entangling, uprooting, and scattering shell. Frankenberg (1995) studied the state of the oyster fishery and concluded that, because of its intensity, trawling had a significant negative impact on live shell bottom habitat. Illegal trawling in prohibited areas can also be a problem, and the penalties for getting caught are minimal. *Stronger penalties are needed for trawling over oyster rocks, where prohibited by the MFC.*

There are approximately 16,000 trips annually with these gears, primarily (>70%) shrimp trawling (DMF, unpub. data). About 75% of the trips occur in estuarine waters, and the rest are mainly within the Territorial Sea. Virtually all shrimp and crab trawling occurs on sand/mud bottoms. Shell bottom is protected from bottom trawling in trawl net prohibited areas [MFC rule 15A NCAC 3J .0104]. Furthermore, it is illegal to use trawls on shell bottom designated as Shellfish/Seed Management Areas [MFC rule 15A NCAC 03K .0103(b)]. These areas are designated by proclamation and must be marked with signs or buoys. The DMF lacks the resources to mark, maintain, and enforce restrictions on all shell bottoms. *Additional marking of productive shell bottom would provide increased protection of this habitat from destructive fishing gears. However, additional law enforcement resources are necessary to mark and enforce increased closed areas.*

Hand harvest

The harvest of clams or oysters by tonging or raking on intertidal oyster beds causes damage to not only living oysters but also the cohesive shell structure of the reef (Lenihan and Peterson 1998). This destruction has been an issue where oysters and hard clams co-exist, primarily around the inlets in the northern part of the state and on intertidal oyster beds in the south (DMF 2001a). Studies by Lenihan and Micheli (2000) and Noble (1996) quantified the effects of oyster and clam harvest on oyster rocks. The former study found that the density of live adult oysters was significantly reduced where clam harvesting

occurred. Mortality was attributed to oysters being cracked or punctured and subsequently dying or being eaten by predators, or by being smothered beneath sediments associated with clam digging. Conversely, oyster harvesting had little effect on clam populations. DMF conducted field investigations of the status of oyster rocks in Ward Creek, Carteret County, to assess the destruction of oyster rocks by individuals taking clams by legal hand harvest methods (Noble 1996). The 1995 survey determined that the oyster rocks had been impacted and, subsequently, the affected portion of Ward Creek was designated a shellfish management area and was temporarily closed to clamming from December 1995 to March 1996. Oysters could only be harvested by hand in the Ward Creek shellfish management area during the 1995–1996 oyster season. Based on visual inspection and field sampling in 1996, the structural integrity and oyster abundance on six of the eight oyster rocks surveyed was good and, in most cases, had improved following the implementation of the shellfish management area restrictions. Because the restrictions were successful in curbing the destruction and deterioration of Ward Creek oyster rocks, it was recommended that the shellfish management area designation be continued to protect oyster rock habitat in Ward Creek. The investigators concluded that by preventing the destruction of oyster rocks, optimum substrate for oyster-spat settlement and critical habitat for other estuarine species would be preserved.

The MFC has recognized that clamming can have a negative impact on oyster habitat and has adopted rules that prohibit the harvest of clams on posted oyster beds and restrict the areas and gear that can be used to take clams and oysters (DMF 2001a). The posting of all natural oyster beds has never been attempted, because of the large number of areas that would have to be posted and the lack of sufficient resources and enforcement to keep them marked. The DMF has designated some areas as Shellfish Management Areas where enhancement activities are conducted (shell is added and/or oysters are transplanted), and clamming is restricted or prohibited. Existing Shellfish Management Areas, about 752 acres of shell bottom, are shown in Map 3.4a-b. *Creation of additional Shellfish Management Areas would reduce habitat damage and enhance spatfall of oysters and clams in areas where hand-harvesting activity is intense. More enforcement would also be needed to enforce the restrictions associated with Shellfish Management Areas.*

Water-dependent development

Water-dependent development includes any permanent, man-made structures that are designed for access to the water (Kelty and Bliven 2003). These include marinas, docks, piers, and bulkheads. Although the construction of water-dependent structures may actually increase substrate for oysters, activities associated with water-dependent development can harm shell bottom. Dredging of channels for navigational purposes can remove, damage, or degrade existing shell bottom. Dredging creates turbidity that can clog oyster gills or cover the oysters completely. Even low levels of siltation affect growth of oyster beds by reducing larvae attachment. Although there are no major new channels being constructed at this time in North Carolina's estuarine waters, maintenance dredging, construction of new marinas and docking facilities, and new dredging for deep water access continue to be potential problems. Primary Nursery Areas are currently protected from dredging projects for deep-water access. However, there are other areas with shallow oyster beds that are not protected from such dredging. Oyster beds in closed shellfishing waters are particularly vulnerable to loss and degradation from marina dredging. *These areas should be evaluated for protection as Strategic Habitat Areas.*

Turbidity and siltation over shell bottom can also occur from increased boating activity near the marina or dock. Boats running in shallow water cause resuspension of fine sediments, which is similar to the effect of dredging on nearby oyster beds. However, the impact of both dredging and boating activity on oysters has been difficult to quantify (Kelty and Bliven 2003). Current (January 2003) CRC marina siting rules discourage significant degradation of existing shellfish resources [CRC rule 15A NCAC 07H .0208]. Marina siting data collected by DCM during 1994-1995 indicate that 44% of the 182 coastal marinas adjacent to mapped bottom areas were located within 100 m (328 ft) of shell bottom (DCM, unpub. data), indicating the potential for shell bottom to be affected by marina-related activities.

Marinas can also negatively impact shell bottom through water quality degradation due to increased runoff and erosion from adjacent developed areas and discharges from boats.[9] Due to the potential for physical and water quality impacts, a variety of rules apply to development of new marinas. The DCM is responsible for permitting marinas under the CAMA. The CAMA permitting process requires coordination with DEH, DMF, DWQ, and other state and federal agencies. If the marina is located in waters that would be classified as shellfishing waters (SA) by the EMC, then a review of the status of the waters is required. If the waters are currently classified as open to shellfishing, then DWQ would recommend denying the permit to protect the designated use of those waters. However, if the waters are closed to shellfishing or not classified as SA, then the marina may be allowed. This policy can unintentionally result in degraded areas being targeted for additional development and further degradation, rather than restoration. *A variety of working groups have recommended the development of a coastal marina policy that encompasses all associated regulatory activities conducted within the DENR (NC Coastal Futures Committee 1994, Waite et al. 1994). Development of this policy continues to be a management need.*

Scouring of the bottom by frequent boat traffic associated with dock concentrations can have an effect similar to dredging. Unlike marinas, individual docks and piers can be built in open shellfish waters. Dock proliferation in coastal waters is a growing concern for resource managers. Concerns raised at a NOAA workshop regarding environmental impacts of boating associated with small docks and piers included erosion of marsh edge and tidal flats, and resuspension of sediment and resulting turbidity (Kelty and Bliven 2003). The workshop participants agreed that boating traffic associated with docks is far from a benign influence on aquatic and marine environments. *Evaluation of the impact of dock-associated boating on shell bottom habitat is therefore a research need. Prohibiting construction of docks or replacement of severely damaged docks (>50%) in documented shellfish beds may be required to minimize degradation and loss of habitat.*

Water quality degradation

Sediment

In addition to direct physical damage to the shell mound structure, bottom disturbing fishing gear, including hydraulic clam dredges, clam trawls (kickers), and shrimp and crab trawls can impact oyster reefs indirectly by re-suspending sediment. As sediment disperses away from the disturbance and settles to the bottom, it can bury oyster larvae, adults, or shell, deterring successful recruitment of larvae due to lack of an exposed hard substrate (Coen et al. 1999). Excessive sedimentation can also harm shellfish by clogging gills, increasing survival time of pathogenic bacteria, or increasing ingestion of non-food particles (SAFMC 1998a). Oyster eggs and larvae are most sensitive to suspended sediment loading (Davis and Hidu 1969a). Sediment was listed by DWQ as a problem parameter for 964 miles of North Carolina waterways in 125 water bodies, including 25 water bodies in the Cape Fear River basin, 18 in the Neuse River basin, and 11 in the Tar- Pamlico River basin in 1998-1999 (DWQ 2000a). All of these river basins contain shell bottom habitat.

There are many other sources of human-induced turbidity and sediment pollution. Any activity that involves clearing of vegetation, grading, and ditching of land can potentially increase erosion and sediment loading in stormwater runoff. These activities include, but are not limited to, construction of residential, commercial, or transportation structures; forestry planting, grading, or harvesting; and agricultural activities. Increased sedimentation in headwaters from upland development has caused environmental stress and possibly some mortality to upstream oyster stocks (Ulanowicz and Tuttle 1992; Mallin et al. 1998). There is anecdotal evidence that sedimentation from upstream development (primarily road construction) has silted over numerous oyster beds in trunk estuaries such as the Newport River, where Cross Rock (a large oyster rock) has been buried under 1-2 feet of soft sediment (P. Pate,

[9] Water quality impacts are discussed under "Water quality degradation."

DMF, pers. com., 2004; C. Peterson, UNC-CH, pers. com., 2004). *Improved voluntary and regulatory land use strategies must be implemented to reduce nonpoint source pollution in coastal waters and subsequent habitat degradation. Mitigation should be required from upstream development projects that result in habitat loss downstream.* Shoreline erosion increases the amount of sediment transported into the estuarine system. While bulkheads can retain some upland sediment, such structures can increase erosion at the base of and downstream from the hardened structures, causing chronic increased turbidity in those areas.[10]

Sediment in excessive amounts is also a problem because it transports fecal coliform in stormwater further downstream and allows the bacteria to persist longer in the water column than such bacteria would live in clear waters (Schueler 1999). While fecal coliform bacteria do not affect the viability of oysters, pathogenic bacteria can make oysters unfit for human consumption. Sediment was the largest cause of water quality degradation in the Albemarle-Pamlico estuarine area (DEM 1989).

The North Carolina Division of Forest Resources (DFR) developed Forest Practice Guidelines and Best Management Practices (BMPs) related to water quality in 1989 to minimize water quality degradation from silvicultural practices. To remain exempt from the requirements associated with the Sedimentation Pollution Control Act, timber-harvesting activities must follow certain performance standards, including establishment of Streamside Management Zones (SMZ). These zones are areas covered with vegetation on both sides of natural intermittent and perennial streams, rivers, ponds, and other water bodies where extra precautions are used during forestry operations to protect stream banks and water quality. In low slope areas (0-5%), the minimum recommended SMZ is 50 feet. Along steeply sloping shorelines of public water supplies, the recommended SMZ is 200 feet [Forest Practice Guidelines Related to Water Quality; EMC rule 15A NCAC 01I .0201-.0209]. Roads are to be placed outside of the SMZ, and harvesting is limited so that the vegetation will trap and filter sediment and other pollutants before reaching the stream, maintain water quality, and provide riparian habitat and shade for fish.

In 1995, the DFR conducted a statewide survey of forestry BMP implementation and compliance. The results found overall compliance was 92% (Henson 1995). The lowest level of BMP compliance was on small non-industrial private forests. Compliance was significantly greater on sites having a professional forester involved with the operation. Although there was very high compliance with having a SMZ, some zones did not have adequate buffer widths, nor tree and/or ground cover, and thus, were not effective. The Division of Forest Resources inspects about 50% of all harvested sites for compliance with Forest Practice Guidelines Related to Water Quality (FPGs) (<http://www.dfr.state.nc.us/water_quality/wq_2000fpgreport.htm>, June 2004). The DFR assert that complaints and observations of harvest operations catch the majority of violators. In FY 1998-1999, the compliance rate statewide for all sites inspected was 95.5%. Of those 4.5% that were out of compliance, the vast majority were brought into compliance. The remainder were referred to the appropriate agency for enforcement action. *Requiring professional foresters to be involved with the implementation of logging BMPs, even on small private forests, would enhance proper use of BMPs. In addition, notifying the Division of Forest Resources prior to initiating logging operations would facilitate BMP inspections and, hopefully, improve overall compliance. Educating owners of small non-industrial forests would also improve BMP implementation and success.*

Nutrients

Increased nutrient loading can indirectly damage live shell bottom by increasing the occurrence of plankton blooms and low oxygen events. Research indicates that the spatial occurrence and frequency of eutrophication in coastal waters has increased (Paerl et al. 1995). Increasing eutrophication, in turn, has caused the frequency, duration, and spatial scale of low or no oxygen events (hypoxia and anoxia, respectively) to intensify over time in many estuaries (Lenihan and Peterson 1998). Prolonged periods of

[10] The Water Column chapter contains a more thorough discussion of sedimentation and turbidity.

low oxygen conditions in the water column can cause mass mortality of fishery-disturbed oyster beds or the non-mobile organisms attached to them. Dissolved oxygen concentrations less than 2 mg/l are fatal to sessile biota and stressful to most motile finfish and shellfish species (Paerl et al. 2001; Sparks et al. 1958; Funderburk et al. 1991). Low dissolved oxygen can occur naturally when the water column becomes stratified (not wind mixed) and biological processes deplete oxygen.

In the Neuse River estuary in 1993, Lenihan and Peterson (1998) found that protracted hypoxia/anoxia caused mass mortality of oysters, other invertebrates, and fishes on a low profile oyster reef at all water depths greater than 5 m. Occupancy of crab burrows on an oyster reef decreased from 100% at all depths prior to hypoxia to 0% at 6 m from the water's surface, 75% at 4 m, and 80% at 3 m immediately after a hypoxic event. Mobile invertebrates such as mud crabs (*Panopeus herbstii*) avoided oxygen depletion by moving upward on the reef where possible. As the frequency of hypoxic events increases, food availability for species that forage on oyster reefs, such as red drum, weakfish, summer flounder, spot, Atlantic croaker, striped bass, and black sea bass will decrease, particularly in deeper habitats and where oyster reef height has been reduced by fishing efforts.

Data have shown that eutrophication, as indicated by nutrient concentrations and high chlorophyll *a* concentrations, is a concern in North Carolina coastal waters. According to the DWQ 305(b) report (DWQ 2000a), there are approximately 35,410 acres of waters impaired by excessive chlorophyll *a* levels. In an EPA sponsored four-year study in North Carolina, low dissolved oxygen (DO) (potentially related to eutrophication) and low infaunal communities within shellfish waters were most frequently reported in Pamlico River and the lower portion of Neuse River (Hackney et al. 1998). One site in Alligator Bay and another at the mouth of Cape Fear River also had moderate contamination and low DO.

There are multiple sources and activities that contribute to excessive nutrient loading of surface waters, including fertilizer use, discharge of animal and human waste, filling of wetlands, loss of riparian buffers, increased stormwater runoff from developed areas, ditching and channelization, and atmospheric nitrogen deposition from animal operations, internal combustion engines, and industrial burning (Paerl et al. 1995; Cooper and Brush 1991). Catastrophic weather events, such as hurricanes, can also greatly increase delivery of nutrients to coastal waters. The Neuse and Tar rivers carried the equivalent of over half their normal nitrogen and phosphorus loads during one month of flooding following Hurricane Floyd during September–October 1999 (Bales et al. 2000). High volumes of floodwater discharge following the hurricanes and other tropical storms in North Carolina in the 1990s resulted in large-scale events of hypoxia in estuarine waters. In the estuaries of the Cape Fear River, hypoxia (0–2 mg/L) persisted for several weeks following Hurricane Fran and Bertha in 1996 (Mallin et al. 1999b).

Similarly, bottom water hypoxia, followed by increased algal blooms and fish disease, occurred in Pamlico Sound following Hurricanes Dennis, Floyd, and Irene in 1999 (Paerl et al. 2001). Salinity and light penetration also decreased temporarily in both areas. These effects often occur naturally following hurricanes because of the large quantities of swamp water flooding and heavy precipitation. However, environmental damage was considerably increased due to failure of municipal and private waste treatment systems and subsequent sewage diversions into rivers, as well as breaching, overtopping, or flooding of swine waste lagoons by river water, allowing large quantities of swine waste to enter coastal waters (Mallin et al. 1999b). *Nitrogen, phosphorus and sediment loading from waste treatment facilities, animal operations and other sources must be reduced upstream of shell bottom habitat to minimize mortality to shellfish and associated organisms. Construction of high profile oyster reefs in deeper waters is needed to serve as refuge areas during low oxygen events.*

Several initiatives have already been taken to reduce nutrient levels in some areas of the coast. The EMC has designated several coastal river basins as "Nutrient Sensitive Waters," requiring removal of wastewater discharges and other management actions to reduce nutrient inputs (Maps 2.2a-b). The EMC initiated a 50-ft streamside buffer and mandated a 30% reduction in nitrogen loading in the Neuse and

Tar-Pamlico river basins. Several mitigation and restoration projects have been constructed in these river basins, as well. A 12.4 acre tidal wetland was constructed at a large row crop farm in 1999 adjacent to the South River. This stream drains to the lower Neuse River in the vicinity of past algal blooms, anoxia and hypoxia events, and fish kills. Results from 2000 and 2001 indicate that the wetland area effectively reduced nitrogen in runoff by approximately 30% (Poe et al. 2002). *Efforts in wetland restoration, shoreline conservation (vegetative buffers, setbacks), and stormwater management should be a priority in watersheds draining to shell bottom habitat, particularly where oxygen and nutrient problems have been documented. Nutrient loading from point sources must also be reduced through increased inspections and maintenance of sewage treatment facilities, collection infrastructure, and on-site wastewater systems. In systems with an abundance of "black waters" (or swamp water), such as the lower Cape Fear River, investigations should focus on separating nutrient impacts on DO from impacts due to inflow of low DO swamp waters.*[11]

Toxic chemicals

Toxic chemicals can enter estuarine waters and accumulate in the sediment or in filter-feeding shellfish at concentrations that are reported to cause biological effects to oysters and other organisms. Under some conditions, such as spills, toxic chemicals may occur in acutely toxic concentrations. Heavy metals, petroleum products, chlorinated hydrocarbons, polycyclic aromatic hydrocarbons (PAHs), and pesticides (organophosphates) can enter estuarine waters from stormwater runoff in developed areas (Dauer et al. 2000; Williamson and Morrisey 2000). Heavy metals and PAHs may be of particular concern with regard to oyster resources due to bioaccumulation and human health concerns (Sanger and Holland 2002).

Oyster embryos and larvae are more sensitive to toxic chemical effects than adults and juveniles, which are generally more tolerant of contaminants than other estuarine species (Funderburk et al. 1991). Oyster larvae are very sensitive to mercury and silver, and moderately sensitive to copper and zinc. Oyster larvae are relatively insensitive to other heavy metals and most of the pesticides tested (Funderburk et al. 1991). The substances having the most chronic effect on oysters include tributyltin, a few heavy metals, and petroleum hydrocarbons. For acute toxicity and sublethal effects on juvenile oysters, chlorinated pesticides and PCB (Arochlor 1016) are thought to be most damaging. Acute toxicity and chronic or sublethal effects of certain toxic chemicals to oysters and clams, as well as the current North Carolina saltwater surface water quality standards [EMC rule15A NCAC 02B .0200], are listed in Table 3.3. In most cases, existing surface water quality standards are sufficiently stringent to protect these species. There are a couple of pesticides listed in the table for which there is no standard. However, EMC rule 15A NCAC 02B .0208 allows for the calculation of criteria to prevent chronic toxicity due to any toxicant not listed in the rules.

Several studies have documented the effects of toxins associated with marinas on the estuarine environment (Wendt et al. 1990; Sanger and Holland 2002; Steel 1991). Heavy metals and PAHs can cause acute toxicity (mortality) and sublethal stress on oysters (all life stages) and other benthos and fish prey organisms. These toxic chemicals can inhibit reproductive development, release of gametes, fertilization, larval development, and growth of juvenile oysters.

The primary biological effect on oysters from marinas examined in South Carolina was a significant reduction in the density of recruited oyster spat at the marina sites compared to control sites (Wendt et al. 1990). No effect was observed on reproduction (reproductive cycle and gonadal index) or the condition of adult oysters. Three PAHs were detected in marina sediments at concentrations known to be carcinogenic. During the summer months, with increased activity at the marina, several PAHs were detected in oyster tissue at greater levels than occurred at control sites. Copper concentrations in oysters were considerably higher at the marina than at control sites. Other data from South Carolina showed concentrations of copper and zinc in oysters were elevated above statewide averages around a large

[11] See the Water Column chapter for more information on water quality degradation affecting shell bottom.

shipyard and boat repair complex (SC DHEC 1987).

Table 3.3. Comparison of acute toxicity and chronic or sublethal toxicity (µg/l) for oyster and clams with North Carolina's saltwater surface water quality standards of the North Carolina.

Contaminant	Eastern oyster (µg/l)[1]		Hard clam (µg/l)[1]		N.C. surface saltwater standards
	Acute	Chronic	Acute	Chronic	(ug/L)
Aldrin (insecticide)	15	0.1	-	202.5	0.003
Arsenic (metaloid)	7500	-	-	-	10
Atrazine (herbicide)	>30,000	>10,000	-	-	[2]
Cadmium (heavy metal)	2579/39	39	-	-	5
Chlordane (insecticide)	8	6	-	-	0.004
Chromium VI (heavy metal)	10,300	-	-	-	50 (as total)
Copper (heavy metal)	38	50	22	25	3
Dieldrin (insecticide)	67	13	-	-	0.0002
Lead (heavy metal)	2450	-	780	-	25
Mercury (heavy metal)	8	12	20	14	0.025
PCB (polychlorinatedbiphenyl)	10	13.9	-	-	0.000079
Permethrin (insecticide)	>1,000	-	-	-	[2]
Toxaphene (insecticide)	23	40	<250	1,120	0.0002
Tributyltin (antifoulant)	1.5	0.7	0.05	0.08	0.002 (as trialkyltin includes tributyltin)
Zinc (heavy metal)	263	200	190	-	86

[1] Geometric means of literature values from Funderburk et al. 1991.

[2] No numeric standard in rules at this time (2002), but currently use "no toxics in toxic amounts" Environmental Management Commission rule 15A NCAC 2B .0208 to control for substances not listed in the rules.

Leaching of wood preservatives from dock and bulkhead structures may also contaminate live oysters. Chromated copper arsenate (CCA), the most common wood preservative in the United States, consists of copper, chromium, and arsenic. This wood preservative has been shown to leach those heavy metals into adjacent sediments and impact marine benthos (Weis and Weis 1994; Weis et al. 1998). The toxicity of copper, chromium, and arsenic to aquatic organisms is well known (Weis et al. 1998) and all three metals are listed as priority pollutants by the EPA (Hingston et al. 2001). Copper appears to have the most toxic effect on marine organisms and also consistently appears to leach the greatest amount (Weis and Weis 1994).

Weis et al. (1995) found that oysters living on CCA-treated wood in a residential canal had fifteen times more copper (~ 200 µg/g wet weight) and 2-3 times more arsenic than reference oysters, and significantly more digestive system malfunctions. Copper is known to cause this pathology (Weis et al. 1995). Sediment contaminated with CCA has caused toxicity and some mortality to oysters, amphipods, polychaetes, fiddler crabs, mud snails, fish embryos, and sea urchin (Weis et al. 1998). Elevated concentrations of metals and reduced abundance and diversity of the benthic community were found to extend approximately 10 meters from CCA treated bulkheads and one meter from docks, decreasing with distance from the structure (Weis and Weis 1994; Weis et al. 1998). Sediment contamination was higher

in a residential bulkheaded canal than adjacent to bulkheaded open water.

The extent of sediment contamination from CCA could be significant considering the magnitude of preserved timber used in the marine environment for bulkheads, docks, and marinas (Weis and Weis 1994). A pilot study conducted by DMF along approximately seven miles of estuarine shoreline in the southern portion of the coast (Pages Creek and Intracoastal Waterway) found that approximately 21% of the shoreline within the study area was hardened in 1984. By 2000, 37% of the shoreline in the same area was hardened. The most affected area of shoreline was along the waterway, where boat wakes and greater fetch increase erosion problems. In this area, 54% of the project area was hardened. However, even along a protected creek with a wide marsh fringe and little obvious erosion problems, 38% of the shoreline has been hardened. Along Yeopim Creek, a tributary of Albemarle Sound, approximately 1% of the shoreline was hardened in 2000. *This methodology for assessing shoreline hardening could be used for a larger portion of the coast to spatially delineate and quantify where and how much of the shoreline is hardened.*

Toxicity of wood decreases with time, about 50% each day after immersion, with most leaching occurring in the first five to six days (Sanger and Holland 2002), and 99% of the leaching completed in three months. However, dock pilings and bulkheads are replaced periodically, providing a continual source of newly treated wood in coastal waters. The EPA is requiring new labeling on all CCA products specifying that no use of CCA will be allowed after December 2003. In February 2002, the wood-treating industries made a voluntary decision to transition away from use of arsenic-treated wood (CCA) by the end of 2003. Alternative wood preservatives containing copper or other chemicals may have similar toxicity to marine organisms. *Any new wood preservative products should be evaluated for impacts to marine benthos, including oysters*[12].

Fecal coliform bacteria

Elevated levels of fecal coliform bacteria in shellfish and adjacent waters do not kill oysters or clams. Such levels indicate contamination of waters, shellfish, and sediments from warm-blooded animal waste. Because of the sources and pathways of fecal coliforms, high bacteria levels are an indication that other water quality problems may also exist that could impact growth, survival, reproduction, or recruitment of fisheries resources and potentially impact human health through harvest and consumption of contaminated shellfish. Water quality monitoring in several tidal creeks in New Hanover County, found a positive correlation between fecal coliform abundance and turbidity, nitrates, and orthophosphates (Mallin et al. 2000b; 2001b). There was also a correlation between levels of fecal coliform and levels of other pollutants such as toxins and sediment. Similar spatial patterns of increased fecal coliform as well as increased nitrates, chlorophyll *a*, and to some extent, turbidity, were observed at upstream locations in the same study. Highest concentrations at upstream areas were attributed to proximity to development sources and reduced flushing and dilution compared to higher salinity waters near the ICW (Mallin et al. 1998). The majority of fecal coliform contamination has been attributed to non-point stormwater runoff (DEM 1994; Frankenberg 1995; Schueler 1999; Reilly and Kirby-Smith 1999; DMF 2001a).

The relative importance of other non-point sources of fecal coliform pollution has also been investigated. For example, Mallin and Wheeler (2000) found that runoff from golf courses was not a significant source of fecal coliform bacteria to tidal creeks in southeastern North Carolina, although they did contribute to elevated nutrient levels in the water.[13]

Disease

When oysters suffer physiological stress induced by extreme environmental conditions, such as low

[12] See Water Column chapter for management needs concerning toxic contaminants affecting shell bottom.

[13] A more in-depth discussion of fecal coliform is provided in the Water Column chapter.

dissolved oxygen or poor water quality, they become more susceptible to parasitism and disease, such as Dermo and MSX (Lenihan et al. 1999). The parasites *Perkinus marinus* (Dermo) and *Haplosporidium nelsoni* (MSX) have caused significant oyster mortality (Andrews 1988; Hargis and Haven 1988; Kennedy 1996; Lenihan et al. 1999). Disproportionate infection of larger, more fecund (egg producing) oysters (Mackin 1951; Ray 1954; Andrews and Hewatt 1957) may at least partially explain the decline in reproduction and subsequent spatfall that has occurred since 1988 (Marshall et al. 1999), prompting major concerns for oysters as a natural and economic resource.

Dermo has been responsible for the majority of adult oyster mortalities in North Carolina in recent years. Although reported to occur in this state in the 1950s (Chestnut 1955), disease assessments were not attempted until large-scale oyster mortalities occurred during late 1988. Dermo was found at nine of eleven sampling sites, while MSX was found at the other two. While both MSX and Dermo have been documented, Dermo was the major cause of adult mortalities (DMF 2001a). Oysters typically begin suffering Dermo-related mortality at the age of 2 years or approximately 2.5 inches in shell height (DMF 2001a). Rates of Dermo infection in oysters generally increase with water temperature and salinity (Paynter and Burreson 1991). The highest rates of infection occur where salinity ranges from 16 – 20 ppt (Lenihan et al. 1999). The MSX dies when salinities are below 10 ppt for at least two weeks. Heavy rainfall from the several hurricanes in North Carolina during 1996-1999 reduced Pamlico Sound salinities, and consequently, the occurrence of MSX in that area (DMF 2001a).

Location and severity of Dermo infection has varied over the years, but was as high as 98 – 100% through much of the 1990s. It became evident that oysters in the smaller, saltier southern estuaries had higher survival rates at infection rates similar to those occurring in Pamlico Sound oysters. Conditions in these small, high salinity areas with high tidal flow may inhibit mortality by flushing out parasites at a high rate and/or having salinities too high for the Dermo parasite (DMF 2001a). A possible link among low DO, increased availability of iron, and increased parasite activity supports this concept, because these estuaries rarely experience low DO events (DMF 2001a).

Research on experimental oyster reefs in the Neuse River and Pamlico Sound (Lenihan et al. 1999) found that oysters at the base of the reefs, where currents were slowest, food quality lowest, and sedimentation rates highest, had the highest prevalence and intensity of infection with Dermo. In the areas studied, adequate height of the shell bottom structures was necessary for the oysters to grow well and survive disease and pollution. The upper portions of taller structures also allowed a safe refuge for mobile invertebrates and fish when low oxygen events occurred. *Maintenance of high-profile oyster rocks is critical for subtidal oysters to perform their ecological functions, as well as provide resources for harvest.*

Human activities that artificially increase salinity can also indirectly cause additional mortality of oysters from Dermo. Such activities include inlet deepening for navigational channels (SAFMC 1998a) and extensive withdrawal of groundwater and surface water during drought conditions. Cape Fear and Beaufort inlets have been extensively deepened for access to the state ports. Shellfish waters in these areas are the most vulnerable to increases in salinity. *The relative contribution of channel deepening to saltwater intrusion and subsequent oyster mortality must be evaluated in order to determine appropriate management action.*

To protect and restore the oyster resource of the Chesapeake Bay by minimizing the spread of Dermo, a group of scientists from North Carolina, Virginia, and Maryland recommended that a policy be established whereby infected oysters would not be moved into salinities lower than where they set or into areas where disease levels were low, and optimally, infected oysters would not be moved at all (Chesapeake Research Consortium 1999). However, other scientists feel that Dermo is now so widespread that relocation of oysters is not a problem.

Some oysters, although exposed to disease, are able to survive. These "disease resistant" individuals are important to the survival and recovery of oyster populations in North Carolina (Breitburg et al. 2000). Harvesting of large oysters or relaying of large oysters from closed to open harvest areas selectively eliminates this disease-resistant genetic pool from the populations. *Establishment of oyster sanctuaries seeded with disease-resistant brood stock or allowed to naturally develop disease-resistant oysters would enhance the oyster's ability to survive and provide disease-resistant broodstock for repopulating highly impacted areas.*

Introduced and nuisance species

Nuisance and non-native aquatic species are becoming more of a problem throughout the United States. North Carolina shell bottom is at risk from the accidental or intentional introduction of these species. Non-native species enter North Carolina waters through river systems, created waterways such as the ICW, ships discharging ballast water of foreign origin, boats entering North Carolina waters from other areas, and the sale of live fish and shellfish for bait or aquaculture (North Carolina Sea Grant 2000). Oysters have already been impacted by the introduction of the parasites Dermo and MSX. It is suspected that the MSX parasite was introduced with Pacific oysters (*Crassostrea gigas*) (DMF 2001a). Intentional introductions of non-native species are covered under state laws and rules of several commissions. Proposals to introduce organisms not native to North Carolina into the coastal waters of North Carolina, or organisms native to North Carolina when the individuals in question originate outside North Carolina, are subject to MFC rule 15A NCAC 3I .0104. An applicant must submit a written application to the Fisheries Director with sufficient information for the Director to "determine that the action will not pose a significant danger to any native marine resource or the environment." The Director can require an applicant to conduct analyses to aid in evaluation of the application, and hold public meetings concerning the proposal. The Fisheries Director determines whether or not to issue the requested permit.

Zebra mussels (*Dreissena polymorpha*) have not been reported in North Carolina, but have been found in northern Virginia and 20 other states (<http://nas.er.usgs.gov/zebra_mussel/>, 2004). Due the rapid rate that this non-native has spread in the United States since first found in 1986, researchers feel that zebra mussels are likely to infest all southeastern states eventually, with negative impacts to the native freshwater and low salinity mollusks (Neves et al. 1987). Zebra mussels frequently clog intake pipes and smother native mussels and large crustaceans (i.e., crayfish). Most estuarine shell bottom (oyster beds) would not be affected, however, since the upper salinity tolerance limit of zebra mussels is <10 ppt (North Carolina Sea Grant 2000). Although the spread of zebra mussels in Lake Erie has improved water clarity, the effect on most fish populations is still largely unknown (<http://nas.er.usgs.gov/zebra.mussel/docs/sp_account.html>, January 2004). Planktivorous species and life stages would most likely be affected due to competition with the mussel. North Carolina Sea Grant has pursued multi-state and regional efforts to address the issue of aquatic nuisance species introduction and dispersal, primarily through education on the ecological impacts and methods to prevent or control dispersion (North Carolina Sea Grant 2000). It is estimated that 13 species of freshwater mussel could be extirpated from North Carolina streams and rivers if zebra mussels were to invade (North Carolina Sea Grant 2000). Among those native mussel species, four species could become extinct.

As North Carolina's oyster populations have declined, interest in establishing a non-native oyster population has grown. While some oyster introductions have revived or expanded oyster fisheries in some parts of the world (especially in Europe), others have failed or caused problems, such as the destruction of native species by exotic diseases (Andrews 1980; DMF 2001a). If the native oyster stocks cannot recover naturally, establishment of non-native oyster populations could provide complex structure for fish habitat (if the introduced species were reef-builders - some oysters are not), water filtration functions, and preserve a traditional North Carolina fishery.

The Pacific oyster (*Crassostrea gigas*) and Suminoe oyster (*Crassostrea ariakensis*) have been the leading candidates for non-native introductions. Researchers have conducted overboard tests in North

Carolina with Pacific oysters and work is underway with the Suminoe oyster (C. Peterson, UNC-CH, pers. com., 2002). The shells of Pacific oyster were found to be too thin to resist predation by native oyster drills (Debrosse et al. 1996). The Suminoe oyster has proven more promising. Laboratory and field studies conducted on *C. ariakensis* in Chesapeake Bay indicate rapid growth and survival under a wide range of coastal and estuarine conditions (Richards and Ticco 2002). *C. ariakensis* also shows greater disease resistance than native oysters.

There is currently much debate and uncertainty regarding the introduction of non-native oysters (Richards and Ticco 2002). Concerns include long-term survival of introduced species, competition with native oysters, unknown reef-building attributes, cross-fertilization with native species (reducing viability of spat and decrease reproductive success), and introduction of non-native pests with the introduced oysters (DMF 2001a). Policy makers are being faced with a dilemma of incomplete knowledge of the species' life history, lack of consensus among scientists regarding the impact of non-native oysters on Atlantic coastal ecosystems, and pressure from commercial and economic interest to revive a once prosperous oyster industry (Richards and Ticco 2002). *The DMF Fishery Management Plan for Oysters (DMF 2001a) recommended that testing continue on aquaculture use of non-spawning, non-native oysters before decisions are made opposing or supporting introduction.*

A comprehensive study of non-native oyster introductions was completed by the National Research Council of the National Academy of Science in 2003 (NRC 2003). The study identified concerns that should be addressed by decision-makers when the introduction of a non-native oyster is under consideration. The concerns included:

- Viability of introduced stocks in Atlantic coast waters
- Co-introduction of new pathogens and parasites
- Economic and social impacts of a non-native oyster introduction
- Adequacy of regulatory and institutional structure for monitoring and overseeing the interjustisdictional aspects of open water aquaculture

The study concluded that *C. ariakensis* is probably well suited for growth and reproduction in the Chesapeake Bay and similar estuarine habitats on the Atlantic coast. The risk of introducing non-native pathogens and parasites could be reduced by following International Council for Exploration of the Seas protocols. However, it will not be easy for the oyster industry to adapt to dependence on hatchery production of Asian oysters. Furthermore, the existing regulatory and institutional framework was found inadequate for handling interjurisdictional issues. Based on this evaluation, limited aquaculture of triploid oysters was considered the most defensible management option. Other options included prohibition of non-native oyster introduction and introduction of reproductive diploid oysters. The principal recommendation from NRC (2003) was to establish standards and protocols for non-native oyster aquaculture that minimize and monitor the unintentional release of reproductive *C. ariakensis*. *The recommendations provided in NRC (2003) should be considered in developing a comprehensive oyster restoration plan.*

Existing management measures

No amount of oyster restoration will erase the effect of continuing pollution of aquatic systems (Boesch et al. 2001). *Therefore, both restoration efforts and water quality management actions reducing direct and indirect shell bottom loss and degradation are necessary to enhance coastal fish habitat.* Several existing management actions provide some protection or enhancement of shell bottom habitat, including shellfish size and harvest limits, habitat restoration, and closure of areas to harvest or use of certain fishing gears. By EMC rules, all shellfish waters with significant resources are classified as SA waters and are, by definition, High Quality Waters (HQW). In addition, some waters that are classified SA also carry the Outstanding Resource Waters (ORW) classification based on recreational or environmental special uses. These waters are afforded additional protection from construction and runoff under EMC, CRC and Soil

and Water Conservation Commission rules. Maps 2.3a-b show HQW and ORW areas for the CHPP area. The HQW and ORW areas cover 8% and 24% of the shellfish mapping study area, respectively. A total of 142,017 acres out of 362,450 acres of ORW in the CHPP MUs are within the DMF shellfish mapping study area. Of the total bottom area mapped by DMF to date (January 2003), 55% (126,583 acres) is classified ORW.

Under MFC rules, oyster reefs are protected from early harvest by size limit and culling tolerance rules [MFC rule 15A NCAC 03K .0202]. By rule, the minimum size at which oysters can be harvested is based on shell lengths not less than 2.5 in. The Fisheries Director has, by proclamation (an administrative order authorized by the MFC), further restricted harvest to oysters of at least 3 inches in length. The intent of the size limit is to allow oysters to spawn before they are removed from the population, as well as protect sublegals as fecundity increases (C. Hardy, DMF, pers. com., 2002). Oysters reach sexual maturity in their first year and harvestable size in about 3-4 years in Pamlico Sound (Ortega et al. 1990). This size limit provides some protection for young oysters throughout their range in North Carolina and for beds of stunted oysters along the boundary of their range. Stunted oyster beds occur where the salinity range is only marginally suitable for larval survival and growth.

Some planted areas can be designated by proclamation of the Fisheries Director as "Shellfish/Seed Management Areas" (SSMAs) [MFC rule 15A NCAC 03K .0103]. These areas include shellfish populations or shellfish enhancement projects that may produce commercial quantities of shellfish or shellfish suitable for transplanting as seed [MFC rule 15A NCAC 03K .0103a]. Use of trawl nets, long haul seines, and swipe nets is prohibited in SSMAs and, unless open to oyster harvest by proclamation, they are closed to all oyster harvest. There are currently 628 acres of SSMA in the Southern Estuaries and New/White Oak MUs that are part of the DMF shellfish mapping study area (Table 3.4). Cultch planting sites in the Pamlico Sound have not been designated as SSMAs because of the difficulties in enforcing the prohibition of shellfish harvesting on these areas (i.e., small numbers of Marine Patrol Officers patrolling large water bodies (M. Marshall, DMF, pers. com., 2002).

In addition to protection from certain fishing gears in Shellfish/Seed Management Areas, shell bottom is also protected from shellfish harvest in military restricted areas. These areas have served as target and bombing ranges since the World War II period. Military restricted areas cover 24,051 acres of the shellfish mapping study area, and all of these areas have been mapped (Table 3.4). Other area designations protecting shell bottom from specific fishing gear impacts include nursery areas, mechanical oyster harvest prohibited areas, trawl net-prohibited areas, and crab spawning sanctuaries. These areas cover more than half of the shellfish bottom mapping area, leaving the largest unrestricted areas in west and northwest Pamlico Sound, the lower Pamlico and Neuse Rivers, and around Roanoke Island (Maps 3.5a-c). A number of cultch planting sites in the Pamlico Sound area are also closed to mechanical harvest by proclamation annually (Map 3.4a), although none have been designated shellfish management areas (DMF 2001a). *Given adequate enforcement capabilities, additional cultch enhanced and naturally occurring shell bottom (intertidal and subtidal) should be designated as DMF Shellfish Management Areas to protect them from fishing gear impacts.*

Another designation that indirectly provides protection from harvesting in North Carolina is the Division of Environmental Health's (DEH) shellfish harvest closure areas. Based on surveys and bacterial sampling, the DEH may designate waters as closed to shellfish harvesting, on either a full-time basis (permanent closure) or rainfall-dependent basis (conditionally approved). Maps 2.19a-c show the extent of shell bottom within the various DEH shellfish area designations. It should be noted that significant portions of closed shellfish waters are located in areas not suitable for shellfish propagation and maintenance due to low salinity levels or other conditions. There are also some closed areas that have robust oyster populations (C. Peterson, UNC-CH, pers. com., 2003). *The value of closed shellfishing*

waters as oyster sanctuaries should be evaluated.[14]

Table 3.4. Amount of bottom habitat mapped (acres) by the North Carolina Division of Marine Fisheries Shellfish Habitat and Mapping Program within areas receiving specific North Carolina Marine Fisheries Commission designations that restrict fishing activities (as of January 2003).

Marine Fisheries Commission restricted fishing area designation	Amount within the shellfish bottom mapping area	Currently mapped area	% complete
Crab spawning sanctuaries	17,673	12,831	73%
Mechanical clam harvest areas	39,446	29,878	76%
Mechanical oyster harvest prohibited	289,617	169,925	59%
Military restricted areas	24,051	24,051	100%
Permanent Secondary nursery areas	34,825	243	1%
Primary nursery areas	46,941	31,045	66%
Shellfish/seed management areas (SSMA)	628	489	78%
Special secondary nursery areas	30,686	21,889	71%
Taking crabs with dredges	43,318	2,044	1%
Trawl nets prohibited	138,812	37,959	27%

3.5. SUMMARY OF SHELL BOTTOM CHAPTER

Shell bottom habitat is unique because it is the only coastal fish habitat that is also a fishery species (oysters). The ecological value of shell bottom has only recently been recognized to be as or more significant than the fishery itself, since it provides numerous habitat and water quality functions that are vital for fishery and non-fishery species. The ability of shell bottom to withstand moderate turbidity levels allows oysters to clear the water column, encouraging growth of SAV and benthic microalgae. Oysters, SAV, and benthic microalgae quickly process dissolved and suspended material from the water column, thus facilitating the estuaries' role in storage and cycling of nutrients. This process reduces the likelihood of coastal eutrophication and its detrimental effects on fish and fisheries. Oyster beds also increase shoreline complexity, can alter circulation patterns, and enhance fish use of marsh edge habitat. Shell bottom also provides hard structure for attachment of diverse invertebrate species and protective cover for small mobile finfish and invertebrates. Gobies, blennies, hard clams, mud crabs, blue crabs, anchovies, oyster toadfish, and sheepshead are a few of the typical residents of oyster reefs. Research has shown that abundance and production of numerous fishery and prey species are enhanced more by shell bottom than by the surrounding soft bottom. Some of the important fishery species whose production is enhanced by shell bottom include hard clam, black sea bass, gag, tautog, and southern flounder. Shell bottom is federally designated as a Habitat Area of Particular Concern for estuarine dependent snapper-grouper species. The restoration of living oyster beds is therefore critical to the proper functioning and protection of surrounding coastal fish habitats and numerous fishery species.

Shell bottom habitat declined for most of the 20th century. The current distribution of shell bottom has shrunk to a mere fraction of its historical range, when oyster rocks were so abundant that they were considered a hazard to navigation. Anecdotal information suggests that oyster beds have been displaced roughly 10-15 miles (16-24 kilometers) downstream in the Pamlico and Neuse estuaries and completely covered by sediment in other areas. Furthermore, North Carolina's commercial oyster landings have declined about 90% from 1889 to today's low harvest. Most shell bottom losses have been subtidal beds

[14] More discussion of trends related to the DEH areas is provided in the Water Column chapter.

in Pamlico Sound, where DMF has also found declines in spatfall. Although mechanical harvesting of oysters has been greatly restricted, reefs have not recovered, possibly due to stress from water quality degradation and increased occurrence of disease (Dermo, MSX). The loss of habitat could be particularly damaging to fishery stocks associated with shell bottom that are classified as Overfished by DMF, such as tautog, black sea bass south of Hatteras, or the central/southern stock of striped bass.

Oyster dredging, beginning in 1889, is believed to be the major cause of the initial decline in shell bottom. Today the dredge harvest has greatly diminished in North Carolina, although about 42% of shallow estuarine bottom (where oysters could live) is still open to mechanical harvest methods, all in Pamlico Sound. Dredging removes oysters and reduces the vertical profile of oyster rocks, increasing the susceptibility of remaining shell bottom at that location to low dissolved oxygen and possible mortality. Hand harvest methods for oysters and clams can also be destructive, but on a much smaller scale. Other bottom disturbing fishing gears, such as trawls, prevent the establishment of oyster reefs in areas within their historic range. Dredging for navigation channels or marina basins also impacts shell bottom. The downstream displacement of oysters in the Neuse and Pamlico rivers is probably the result of extensive drainage networks designed to increase the flow of stormwater (fresh water) into coastal waterways, decreasing salinity in the downstream portions of those rivers. While drainage for agriculture has changed little, drainage for urban/suburban development is increasing steadily. Runoff from agriculture, urban/suburban development, and transportation infrastructure carries sediment, nutrient, and toxic chemical pollutants. Sediment, the number one pollutant of waterways in the United States, clogs oyster gills and buries shells. Excess nutrients can fuel algal blooms and low dissolved oxygen events, and in turn, cause mortality of benthic organisms on deep, subtidal shell bottom. Heavy metals, petroleum products, pesticides, and other toxic chemicals in the runoff can kill sensitive oyster larvae.

To offset the decline in oyster habitat, restoration efforts were begun in 1958, and some protected areas have been established. While almost all work in the past has focused on restoring oysters for harvest, some recent efforts have been designed to restore or enhance shell bottom for habitat purposes. However, the magnitude of losses still greatly exceeds gains from restoration. Large areas of shell bottom habitat are still unprotected from direct physical removal or damage via human-related activities, as well as from indirect damage from water quality degradation. In order to restore shell bottom habitat, the destruction of oyster beds from fishing practices, channel or marina dredging, and pollutant loading must be reduced and oyster habitat restoration must increase significantly.

CHAPTER 4. SUBMERGED AQUATIC VEGETATION

4.1. DESCRIPTION AND DISTRIBUTION

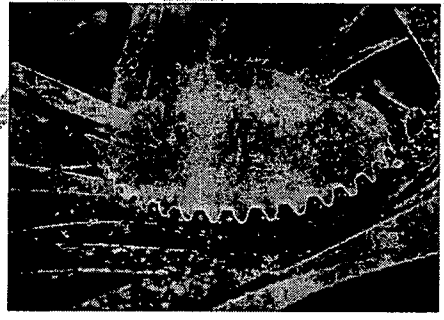
Definition

Submerged aquatic vegetation (SAV) is a fish habitat dominated by one or more species of underwater vascular plants. The North Carolina Marine Fisheries Commission (MFC) and Coastal Resources Commission (CRC) define SAV as:

"...those habitats in public trust and estuarine waters vegetated with one or more species of submerged vegetation such as eelgrass (*Zostera marina*), shoalgrass (*Halodule wrightii*), and widgeon grass (*Ruppia maritima*). These vegetation beds occur in both subtidal and intertidal zones and may occur in isolated patches or cover extensive areas. In either case, the bed is defined by the presence of above-ground leaves or the below-ground rhizomes and propagules together with the sediment on which the plants grow. In defining beds of submerged aquatic vegetation, the Marine Fisheries Commission recognizes the Aquatic Weed Control Act of 1991 (G.S. 113A-220 et. seq.) and does not intend the submerged aquatic vegetation definition and its implementing rules to apply to or conflict with the non-development control activities authorized by that Act" [MFC rule 15A NCAC 03I .0101 (20)(A) and CRC rule 15A NCAC 07H .0208 (6)].

Although not specifically listed in the definitions, SAV beds may also be vegetated with freshwater species such as native wild celery (*Vallisneria americana*) and sago pondweed (*Potamogeton pectinatus*). Submerged aquatic vegetation is included as a Critical Habitat Area under MFC rules [MFC rule 15A NCAC 03I .0100 (b)(20)]. The SAFMC classifies SAV as Essential Fish Habitat for penaeid shrimp, red drum, and snapper/grouper species. Although the MFC and CRC definitions may include areas with only SAV roots or propagules, SAV habitat could also occur on bottom temporarily lacking any SAV structures between patchy SAV beds or where conditions are currently unfavorable for growth, but have historically supported SAV. Therefore, for purposes of this plan, SAV habitat is defined as "bottom recurrently vegetated by living structures of submerged, rooted vascular plants, (i.e., roots, rhizomes, leaves, stems, propagules), as well as temporarily unvegetated areas between vegetated patches."

SAV is an underwater forest for juvenile fish and small invertebrates and a barometer of water quality.



Description

Submerged aquatic vegetation habitat includes marine, estuarine and riverine vascular plants that are rooted in sediment. Although SAV sometimes occurs intertidally or extends to the water's surface, these plants are generally submerged and cannot survive if removed from the water for any length of time (Hurley 1990). Leaves and stems have specialized thin-walled cells (aerenchyma) with large intercellular air spaces to provide buoyancy and support in an aquatic environment. Leaves and stems are generally

thin and lack the waxy cuticle found in terrestrial plants. The lack of a waxy cuticle increases the exchange of water, nutrients, and gases between the plant and the water (Hurley 1990). The extensive root and rhizome system anchors the plants, and also absorbs nutrients (Thayer et al. 1984). Reproduction occurs both sexually and asexually (i.e., vegetatively).

Habitat for SAV in North Carolina consists of two types of SAV communities, both of which are important to coastal fisheries – one in higher salinity estuarine waters and another in lower salinity to freshwater systems (Table 4.1). Estuarine species that occur in North Carolina include eelgrass (*Z. marina*), shoalgrass (*H. wrightii*), and widgeon grass (*R. maritima*). Eelgrass is a temperate species at the southern limit of its Atlantic coast range in North Carolina. In contrast, shoalgrass is a tropical species that reaches its northernmost extent in the state. Widgeon grass has a wide salinity range and grows in both fresh water and high salinity environments, although it occurs most commonly in moderate salinities (about 15 ppt). The co-occurrence of these three SAV species is unique to North Carolina, resulting in high coverage of shallow bottoms in North Carolina's estuaries (Ferguson and Wood 1994). These three species form biological and physical assemblages referred to as seagrass meadows (SAFMC 1998). Seagrass meadows are often defined by a visible boundary marking unvegetated and vegetated bottom varying in size from small isolated patches of plants less than a meter (<3 ft) in diameter to continuous meadows covering many acres. Low salinity species that occur in North Carolina include native wild celery (*V. americana*), non-native Eurasian milfoil (*Myriophyllum spicatum*), bushy pondweed (*Najas guadalupensis*), redhead grass (*P. perfoliatus*), and sago pondweed (*P. pectinatus*) (Ferguson and Wood 1994). There is slightly greater SAV species diversity in coastal riverine systems than marine systems in North Carolina (Odum et al. 1984).

Seagrass habitat supports other types of aquatic plants in addition to submerged grasses. Macroalgae (benthic, drift, and floating forms) often co-occur with SAV and provide similar ecological services, but the plant taxa have distinctly different growth forms and contrasting life requirements (SAFMC 1998). Macroalgae grow faster than SAV and do not require unconsolidated substrate for anchoring extensive root systems. Because of this growth pattern, macroalgae do not provide as much sediment stabilization as submerged rooted vascular plants. Their leaves are also less rigid than those of submerged rooted vascular plants, thus reducing their function as substrate for attachment and as a source of friction for sediment deposition. Macroalgal genera include salt/brackish (*Ulva, Codium, Gracilaria, Enteromorpha*) and freshwater (*Chara* and *Nitella*) species. Macroalgae common to the rivers of the Albemarle Sound system include the charophytes (*Chara* spp.). In addition, the macroalgae *Ectocarpus* and *Cladomorpha* grow on salt marsh flats (Mallin et al. 2000) and in association with SAV beds (Thayer et al. 1984).

Epibiota are another important component of SAV habitat. Epibiota are organisms that attach or grow on the surface of a living plant and may or may not derive nutrition from the plant itself. Micro- and macroalgae (i.e., seaweed) can grow on the leaves of SAV. Invertebrates attached to the SAV leaves include protozoans, nematodes, polychaetes, hydroids, bryozoans, sponges, mollusks, barnacles, shrimps and crabs.

Table 4.1. Average environmental conditions at locations where submerged aquatic vegetation occurred in coastal North Carolina, 1988-1991. *[Source: Ferguson and Wood 1994]*

SAV species	Environmental parameter					
	Salinity (ppt)		Secchi depth m (ft)		Water depth m (ft)	
	Range	Average	Range	Average	Range	Average
HIGH SALINITY SEAGRASS						
Eel Grass	10 - >36	26	0.3 - 2.0 (1.0 - 6.6)	1.0 (3.3)	0.4 - 1.7 (1.3 - 5.6)	1.2 (3.9)
Shoal Grass	8 - >36	25	0.4 - 2.0 (1.3 - 6.6)	1.0 (3.3)	0.1 - 2.1 (0.3 - 6.9)	0.8 (2.6)
Widgeon Grass	0-36	15	0.2 - 1.8 (0.7 - 5.9)	0.7 (2.3)	0.1 - 2.5 (0.3 - 8.2)	0.8 (2.6)
LOW SALINITY SEAGRASS						
Redhead Grass	0-20	1	0.4 - 1.4 (1.3 - 4.6)	0.9 (3.0)	0.4 - 2.4 (1.3 - 7.9)	0.9 (3.0)
Wild Celery	0-10	2	0.2 - 2.0 (0.7 - 6.6)	0.6 (2.0)	0.2 - 2.3 (0.7 - 7.6)	1.0 (3.3)
Eurasian Watermilfoil	0-10	2	0.2 - 1.4 (0.7 - 4.6)	0.6 (2.0)	0.5 - 2.4 (1.6 - 7.9)	1.1 (3.6)
Bushy Pondweed	0-10	1	0.2 - 2.0 (0.7 - 6.6)	0.7 (2.3)	0.5 - 1.7 (1.6 - 5.6)	1.0 (3.3)
Sago Pondweed	0-9	2	0.2 - 0.4 (0.7 - 1.3)	0.3 (1.0)	0.6 - 0.9 (2.0 - 3.0)	0.8 (2.6)

The three-dimensional shape of SAV habitat can be quite variable, ranging from highly mounded, patchy beds several yards wide, to more contiguous, low-relief beds (Fonseca et al. 1998). Leaf canopies formed by the seagrasses range in size from a few inches to more than three feet (0.91 m) tall. The structural complexity of an SAV bed also varies somewhat because of the growth form of the species present (SAFMC 1998). While leaf density tends to be higher in contiguous beds than in patchy SAV habitat, below-ground root-mass is often higher in patchy beds (Fonseca et al. 1998). Patchiness in seagrass bed distribution can result from new beds sprouting from seed or from existing beds that are fragmented by high wave energy or currents (Thayer et al. 1984). The rate that an area of unvegetated bottom can become vegetated may vary on the scale of days or decades, depending on the species and the physical conditions (Fonseca et al. 1998). Consequently, to maintain patchy seagrass beds, an area of shallow soft bottom must be maintained that is at least two times greater than the area of actual SAV coverage (Fonseca et al. 1998). Despite the difficulty of defining the boundaries of seagrass beds, unvegetated bottom between nearby adjacent patches is included as a component of patchy SAV habitat since rhizomes may be present and the beds "move" around with patterns of sediment erosion and deposition (Fonseca et al. 1998). Patchy habitats provide many ecological functions similar to continuous beds (Murphey and Fonseca 1995; Fonseca 1996b).

The dynamic nature of seagrass beds has important implications for fisheries habitat. Seagrass habitat can change at a scale of hours to decades (Fonseca et al. 1998; SAFMC 1998). Therefore, one should

consider historical as well as current SAV occurrence to determine locations of viable seagrass habitat (SAFMC 1998). Seagrass abundance and biomass fluctuate seasonally (Dawes et al. 1995). In North Carolina, annual meadows of eelgrass are common in shallow, protected estuarine waters in the winter and spring when water temperatures are cooler. However, in the summer when water temperatures are above 25 – 30°C (77 – 86°F), shoalgrass is more abundant, and eelgrass thrives only where water temperatures are lower (i.e., deeper areas and tidal flats with continuous water flow (SAFMC 1998).

Habitat requirements

Beds of SAV occur in North Carolina in subtidal, and occasionally intertidal, areas of sheltered estuarine and riverine waters where there is unconsolidated substrate (loose sediment), adequate light exposure on the bottom, and moderate to negligible current velocities or turbulence (Thayer et al. 1984; Ferguson and Wood 1994). The factors generally considered to limit the success of SAV are light, salinity, wave energy, and nutrients. Specific habitat requirements for individual species are presented in Table 4.1.

The primary factor controlling distribution of SAV is the penetration of light through the water column (Duarte 1991; Kenworthy and Haunert 1991; Goldsborough and Kemp 1988; Stevenson et al. 1993; Dennison et al. 1993; Virnstein and Morris 1996). Availability of light to SAV is determined by water clarity, also known as "transparency." Water clarity can be quantified indirectly by measuring turbidity (nephelometric turbidity units or NTU) or secchi depth (maximum depth where a standard object can be seen by the human eye), or directly by measuring the amount of sunlight that penetrates through the water and reaches the leaves of underwater grasses. At a minimum, seagrasses require 15-25% of the light that is available on the water's surface to reach them (Dennison and Alberte 1986; Kenworthy and Haunert 1991; Bulthius 1994; Fonseca et al. 1998). If less light is available, photosynthesis is limited, reproduction may be inhibited, and growth and survival of the submerged vegetation can not be sustained.

Water clarity can be reduced by natural substances in the water column, such as dissolved organic matter (e.g., humics), suspended particulate matter (e.g., sediment and minerals), detritus, and algae. As the water column becomes more turbid and less transparent, light attenuation (absorption and scattering of light by particles in the water column) increases. Water color also affects light penetration. For example, dissolved organic matter such as tannic acid (produced naturally in swamp waters via breakdown of detritus) and lignins (produced artificially as a byproduct of wood pulp mill processing) strongly absorbs blue light. Seagrasses generally cannot survive below a certain depth because of light limitations. Therefore, as water clarity declines, SAV beds in deeper waters are lost first. In coastal North Carolina, SAV can grow in water up to 2.5 m (8.20 ft) deep and secchi depths averaging approximately one meter (3.28 ft) (Ferguson and Wood 1994) (Map 4-1).

Light and water quality requirements for SAV in Chesapeake Bay were reevaluated and revised in 2000 by the Chesapeake Bay Program in a technical synthesis (EPA 2000). These requirements are listed in Table 4.2 by salinity regime. The primary limiting factor is light; sufficient light must reach the SAV so that photosynthesis can occur. The EPA partitions available light into two categories. The "water column light requirement" refers to the amount of light penetrating through the water column. The "light at leaf requirement" refers to the amount of light that can penetrate the leaf surface due to epibiotic coverage. Environmental conditions that allow adequate light penetration for SAV survival are total suspended solids (TSS) less than 15 mg/l and chlorophyll *a* less than 15*ug*/l. No secchi depth or turbidity values were recommended. In contrast, preliminary bio-optical modeling suggests that the water conditions required for seagrass survival may be less stringent in North Carolina's North River relative to conditions in the Chesapeake Bay (P. Biber, NMFS, pers. com., 2003). Specifically, the maximum values of TSS and chlorophyll *a* that can occur at any given depth and still allow SAV survival may be somewhat higher than that needed in Chesapeake Bay. Greater tidal current magnitude (causing the prolonged suspension of relatively larger particles) and decreased absorption/scattering capacity of phytoplankton species and sediment types specific to North Carolina may be responsible for the observed regional differences (P.

Biber, NMFS, pers. com., 2003). Given certain combinations of turbidity and nutrients, North Carolina's current standards may not be adequate to sustain SAV (P. Biber, NMFS, pers. com., 2003). *Additional estuaries should be modeled to determine environmental requirements for SAV over a broader scale and to determine if changes in EMC water quality standards are needed.*

Table 4.2. Recommended primary and secondary submerged aquatic vegetation habitat requirements for the Chesapeake Bay and its tidal tributaries classified by salinity regimes. *[Source: Funderburk et al. 1991; EPA 2000]*

		Primary Requirements[1]		Secondary Requirements[2]			
Salinity regime (ppt)	SAV growing season	"Light at leaf" requirement	Water column light requirement	Total Suspended Solids (mg/l)	Chlorophyll a (ug/l)	Dissolved inorganic phosphorus (mg/l)	Dissolved inorganic nitrogen (mg/l)
Tidal fresh	April-October	>9%	>13%	<15	<15	<0.02	none
0 .5 - 5.0	April-October	>9%	>13%	<15	<15	<0.02	none
5.0 - 18.0	April-October	>15%	>22%	<15	<15	<0.01	<0.15
18.0 - 30+	March-May, Sept.-Nov.	>15%	>22%	<15	<15	<0.02	<0.15

[1] Assessed with percent light at the leaf and percent light through the water parameters. All habitat requirements are independent of restoration depth.

[2] Secondary requirements are used to determine possible reason for non-attainment of the primary requirement.

Field sampling of SAV beds in North Carolina between 1988 and 1991 found that occurrence of SAV in the study area was related to water depth, water clarity as measured by secchi depth, and salinity. This study did not measure light attenuation or percent light availability (Ferguson and Wood 1994). Environmental conditions where SAV species occurred are listed in Table 4.1. In the area sampled, average depth of SAV occurrence ranged from 2.63–3.94 ft (0.8–1.2 m), depending on the species. The maximum depth of observed presence, regardless of species, was 7.87 ft (2.4 m) (Ferguson and Wood 1994). Data indicated that freshwater SAV had a somewhat greater tolerance to turbidity than salt and brackish seagrasses, since they were found in areas of similar water depths to high salinity grasses, but secchi depths were less (Ferguson and Wood 1994). This feature supports other research (Funderburk et al. 1991) showing that salt/brackish seagrasses require slightly greater water clarity (secchi depth >1.0 m, or 3.28 ft) than freshwater SAV (secchi depth >2.63 ft or 0.8 m).

Other physical and chemical factors that impact SAV include salinity, nutrients, and wave exposure. The average salinity for freshwater SAV is between 1 and 2 ppt, while the average salinity for salt/brackish SAV ranges from 15 to 26 ppt (Ferguson and Wood 1994) (Table 4.1). Widgeon grass occurs in both high and low salinity waters, with an average salinity of 15 ppt. Salt/brackish SAV requires less than 0.15 mg/l of dissolved inorganic nitrogen and less than 0.01 mg/l of dissolved inorganic phosphorus (Funderburk et al. 1991). The majority of nitrate used by SAV is derived from the sediment, rather than the water column (Thayer et al. 1984). Contiguous beds of eelgrass or other species of SAV rarely occur in windswept areas or where currents are strong (>20-40 cm/s) (Thayer et al. 1984; Fonseca et al. 1998). Work was done in Core Sound by Fonseca et al. (1998) to analyze the effect of wave exposure and currents on SAV coverage. They found significant relationships, with percent cover of SAV decreasing with increasing relative wave exposure indices or current speed. *This information could be used to determine habitat suitability for SAV restoration in Core Sound. A similar process could be conducted in other areas, particularly low salinity areas, where large losses of SAV have historically occurred. Alternative measures of restoration site suitability could be investigated in areas where the Fonseca wave exposure model has yet to be tested (P. Biber, NMFS, pers. com., 2003; <http://www.marine.unc.edu/Paerllab/research/seagrass/field_experiments.htm>, 2003).*

Below is a brief description of the habitat and plant characteristics of the five submerged grasses common

to North Carolina's brackish to freshwater systems and the three submerged grasses common to high salinity estuarine waters (Hurley 1990). Widgeon grass is included with high salinity grasses, but it can tolerate low salinity as well.

High salinity grasses

- Eelgrass (*Zostera marina*): Grows in fine muds, silts, and loose sand in high salinity waters and can tolerate high energy waters (Thayer et al. 1984). Reproduces vegetatively from October to June, and sexually from December to April. Present primarily as a seed-bank from July to November (P. Biber, NMFS, pers. com., 2003). Rhizomes rarely deeper than 5 cm (1.97 inches). Can spatially coexist in beds with *Halodule* in North Carolina, but is dominant from winter to summer, with lower densities during summer months relative to that of *Halodule* (Thayer et al. 1984).
- Widgeon grass (*Ruppia maritima*): Tolerates a wide range of salinity regimes. Slightly brackish to moderately brackish and high salinity. Found growing with eelgrass. Widgeon grass is more common in shallow areas, with eelgrass in deeper waters. Spreads vegetatively from creeping rhizome during April - October. Rare occurrence reported in fresh water. While more common on sandy substrates, is also found on soft, muddy sediments. High wave action damaging to slender stems and leaves.
- Shoalgrass (*Halodule wrightii*): Forms dense beds and can occur in very shallow water. Known for its relative tolerance to desiccation (drying out) once rooted. Rhizomes situated fairly shallow in sediment and may extend into the water column with attached shoots. Almost exclusively vegetative (asexual) reproduction from April through October and sexually on a very rare basis in spring and summer (J. Kenworthy and P. Biber, NMFS, pers. com., 2003). Due to its clonal reproductive strategy, genetic diversity may be quite limited and, as such, populations may be at particular risk to changing estuarine conditions (P. Biber, NMFS, pers. com., 2003). May co-occur with *Zostera* and dominates mid-summer through fall in North Carolina, after which *Zostera* becomes relatively more predominant (Thayer et al. 1984).

Low salinity grasses

- Bushy Pondweed or Southern Niad (*Najas quadalupensis*): Present in small freshwater streams. Also tolerates slightly brackish waters. Sand substrates preferred. Can grow in muddy soils. *Najas* spp. requires less light than other SAV species.
- Wild celery (*Vallisneria americana*): Primarily a freshwater species occasionally found in moderately brackish waters. Coarse silt to slightly sandy soil. Tolerant of murky waters and high nutrient loading. Can tolerate some wave action and currents compared to more delicately leaved and rooted species. Similar in appearance to eelgrass.
- Sago pondweed (*Potamogeton pectinatus*): Fresh to moderately brackish. Tolerates waters with high alkalinity. Associated with silt-mud sediments. Long rhizomes and runners provide strong anchorage to the substrate. Capable of enduring stronger currents and greater wave action than most other SAV.
- Redhead grass (*Potamogeton perfoliatus*): Found in fresh to moderately brackish and alkaline waters. Grows best on firm muddy soils and in quiet waters with slow-moving currents. Because of its wide leaves more susceptible to being covered with epibiotic growth then the more narrow leaved species. Securely anchored in the substrate by its extensive root and rhizome system.
- Eurasian watermilfoil (*Myriophyllum spicatum*): This species inhabits fresh to moderately brackish waters. Affinity for water with high alkalinity and moderate nutrient loading. Grows on soft mud to sandy mud substrates in slow moving stream or protected waters. Not tolerant of strong tidal currents and wave action. Over-wintering lower stems provide early spring cover for fish fry before other SAV species become established. *M. spicatum* is a non-native, invasive species, estimated to cover over 4000 acres in Currituck and Albermarle Sounds during the 1990s (DWR 1996), and is classified by the North Carolina Board of Agriculture as a Class B noxious

weed [02 NCAC 48A .1702].

Distribution

Seagrasses occur along the entire east coast of the United States, with the exception of South Carolina and Georgia, where high freshwater input, high turbidity, and large tidal amplitude (vertical tide range) inhibit their occurrence. The most recent estimate for estuarine SAV in North Carolina is approximately 200,000 acres (80,937 hectares(ha)) (Ferguson and Wood 1994), or about 7% of the estuarine bottom in North Carolina. Along the Atlantic coast, North Carolina supports more SAV than any other state, except for Florida (Table 4.3). Based on interpretation and ground-truthing by NOAA of remotely-sensed imagery taken during 1985-1990 (Ferguson and Wood 1994), areas of visible SAV were mapped as follows:

SAV Distribution in North Carolina	
Eastern Pamlico Sound	90,000 acres (36,421.71 ha)
Core Sound	19,938 acres (8,068.62 ha)
Albemarle Sound	4,439 acres (1,796.39 ha)
Croatan/Roanoke Sounds	926 acres (374.74 ha)
Neuse River estuary	91 acres (36.83 ha)
Pamlico River estuary	378 acres (152.97 ha)
Western Pamlico Sound	83 acres (33.58 ha)

Table 4.3. Estimated spatial coverage of submerged aquatic vegetation in coastal waters of mid- and south Atlantic states.

State	SAV		Source
	acres	hectares	
Florida	2,658,290	1,075,772	Sargent et al. (1995)
North Carolina	200,000	80,937	Ferguson and Wood (1994)
Chesapeake (Va and Md)	59,300	23,998	Funderburk et al. (1991)

In 1981, visible SAV in Core and Bogue sounds covered 19,458 acres (7,874.37 ha) within a total water area of 104,840 acres (42,427.24 ha) (19% SAV coverage; Carraway and Priddy 1983). However, acreage for these areas may be underestimated, particularly in low salinity riverine areas, since aerial photography at the scale utilized (1:24,000) may not be able to detect some SAV due to the relatively small patch size and high turbidity of the water.

Physical and chemical conditions of the Albemarle-Pamlico estuarine system provide suitable habitat conditions for SAV growth. The extensive barrier islands of the Outer Banks protect the east side of Pamlico Sound and other smaller sounds within the Albemarle-Pamlico estuary. Tides and currents are primarily wind-driven. The western shorelines of the sounds are less protected from the wind, but because of the reduced currents and tidal amplitude, they also support SAV growth where water depth is shallow enough and water quality conditions allow. Aside from physical and chemical limitations, survival of SAV can be affected by excessive covering of drifting macroalgae or epiphytes, and disease outbreaks like eelgrass wasting disease (Stephan and Bigford 1997). In Florida Bay, uncommon yet large-scale grazing events by urchins (Rose et al. 1999) restricted seagrass distribution. It is unknown if similar overgrazing incidents by these or other organisms have affected seagrasses, recently or historically, in North Carolina.

At present, SAV habitat in coastal North Carolina occurs mostly in sandy and muddy sediment and high salinity waters along the estuarine shoreline of the Outer Banks, with sparse cover along much of the

mainland shores of the estuarine system (Ferguson et al. 1989). Within the Coastal Plain, freshwater SAV is locally abundant in some larger blackwater streams and rivers, but is rare in small blackwater streams (Smock and Gilinsky 1992) due to shading from forested wetlands and irregular flows typical of low order streams. Freshwater SAV can be extensive in some low-salinity back bays and lagoons (Moore 1992), and may also occur in coastal lakes such as Lake Mattamuskeet.

Limited SAV distribution and lower species diversity of SAV have been associated with areas of low salinity (5–18 ppt) (Ferguson and Wood 1994). Seagrasses in these regions may be limited by long wind fetch (the horizontal distance over which wind blows, creating waves), lack of protected shallow bottom, extreme currents, reduced light availability, and excessive nutrient enrichment. Shoalgrass or eelgrass were not observed in western Pamlico Sound or the Pamlico or Neuse estuaries despite acceptable salinity ranges. The presence of SAV in low salinity waters (<5 ppt) of Albemarle and Currituck sounds and their tributaries was relatively low (Ferguson and Wood 1994). Map 4.2 shows SAV areas mapped by Carraway and Priddy (1983) and Ferguson and Wood (1994). The area of SAV habitat within CHPP management units is presented in Table 4.4.

Table 4.4. Submerged aquatic vegetation (SAV) coverage within Coastal Habitat Protection Plan management units (MU) based on mapping work of Carraway and Priddy (1983) and Ferguson and Wood (1994).

	SAV		Total Water*		
MU	acres	hectares	acres	hectares	% SAV
Albemarle	13,638.37	5,519.25	604,416.92	244,598.85	2.26
Core/Bogue	36,188.68	14,645.04	167,946.49	67,965.53	21.55
Neuse	95.72	38.74	112,816.70	45,655.30	0.08
Pamlico	83,403.19	33,752.07	1,020,521.96	412,990.59	8.17
Tar/Pamlico	392.14	158.69	117,122.97	47,397.98	0.33
Total	133,718.09	54,113.79	2,022,825.04	818,608.26	6.61

*Water area includes broad open waters detected on 1:100,000 scale USGS topographic maps

Estuarine SAV occurs sporadically west of Bogue Inlet to the border with South Carolina, but these areas have not been suitably photographed (Ferguson and Wood 1990). Small areas of SAV habitat have been observed in the past few years by DMF biologists in the New River, Alligator and Chadwick bays, Topsail Sound and inside Rich's Inlet (M. Allison, DMF, pers. com., 2002). Other studies reporting distribution of salt/brackish SAV include Davis and Brinson (1983) for Currituck Sound, Brinson and Davis (1976) for the Chowan River, and DWQ (1998) for the Neuse River. The U.S. Fish and Wildlife Service's National Wetland Inventory (NWI) Program has mapped some SAV in inland fresh waters. However, this information has not been summarized by CHPP management unit or region.

4.2. ECOLOGICAL ROLE AND FUNCTIONS

Submerged aquatic vegetation provides important structural fish habitat and other important ecosystem functions in estuarine and riverine systems in coastal North Carolina. The SAFMC (1998) recognized SAV as an essential fish habitat because of five interrelated features of seagrass meadows – primary production, structural complexity, modification of energy regimes, sediment and shoreline stabilization, and nutrient cycling. Water quality enhancement and fish utilization are especially important functions of SAV relevant to the enhancement of coastal fisheries.

Productivity

Seagrass habitat is dominated by dense stands of primary producers – underwater grasses. These grasses produce large quantities of organic matter. Estimates of daily production for eelgrass beds rank among the most productive of marine plant habitats (Thayer et al. 1984). The typical biomass of growing SAV beds (leaves + rhizomes) in North Carolina was reported as 57–391 g (dry weight)/m^2 (Thayer et al. 1984; Twilley et al. 1985). Primary productivity is derived approximately equally from above ground and below ground growth.

Because of their high rates of primary production and particle deposition, SAV beds are important nutrient sources (nutrients are exported from the bed to other users) and sinks (nutrients are retained within the bed by the plant structure (leaves and roots), especially during high growth periods (SAFMC 1998). Thayer et al. (1984) concluded that SAV beds in high velocity areas are sources of organic matter, while SAV in low current areas are sinks of organic matter (detritus). Important sources of organic matter produced by SAV habitat include the SAV plant tissue, epibiotic organisms attached to SAV leaves, microalgae and macroalgae present on sediments among SAV plants, and dissolved organic matter released during metabolism (SAFMC 1998). Ultimately, large amounts of nutrients, originally retained by SAV, are exported via secondary production and trophic interactions by animals as they depart nursery areas following larval and juvenile development (Thayer et al. 1984).

Attached epibiota contribute substantially to the total productivity of SAV beds (Thayer et al. 1984) and are an important food source for fish and invertebrates. Approximately 25% of the average annual above-ground biomass of an eelgrass bed in the Newport River was attributable to epiphytes (Penhale 1977). In certain instances, total biomass of epibiota can actually exceed that of the SAV leaves to which the epibiota are attached. While they may increase primary productivity of the habitat, epibiota may also significantly reduce productivity of individual plants if coverage is too extensive (Thayer et al. 1984). Dillon (1971) estimated that epiphytic macroalgae constitute 10% of the total SAV biomass in a North Carolina estuary, although seasonal variability in macroalgal abundance corresponds to seasonal fluctuations in eelgrass biomass (Penhale 1977; Thayer et al. 1975).

Exported matter represents a large portion of total SAV production in salt/brackish SAV beds in North Carolina (Thayer et al. 1984). When grasses die and decompose, the detrital material is broken down by invertebrates, zooplankton and bacteria, and energy is transferred through the estuarine detrital food web. Because it breaks down much slower than algae, SAV decomposition generally does not cause anoxic conditions (Hurley 1990). Decomposed SAV matter and its associated bacteria are actually of greater importance as a food source for fish than the living SAV leaves (Thayer et al. 1984).

Ecosystem enhancement

System enhancement includes any positive effect on other habitats provided by proximity to SAV. Because seagrasses are rooted in the substrate and provide long-term submerged structure in estuaries and coastal rivers, system enhancement is one of their more important ecological functions. Some of these functions include (SAFMC 1998):

- Modification of water flow and reduction in wave turbulence,
- Accelerated deposition of sediment and organic matter,
- Physical binding of sediments beneath the canopy, and
- Nutrient cycling between the water column and sediments.

The network of leaves, stems, and roots of an SAV bed oxygenate the surrounding water, filter and trap sediments, and utilize excess nutrients (nitrogen and phosphorus) dissolved in the water (Thayer et al. 1984). These processes increase water clarity and improve conditions for further SAV growth. The absorption of excess nitrogen and phosphorus by SAV can reduce the frequency of nuisance algal blooms and resultant anoxic waters when the blooms die off and decay (Thayer et al. 1984). During active

periods of growth and leaf turnover, nutrients cycle rapidly between plant tissues and the organisms that feed upon them. This retention and controlled release of nutrients improves water quality down current and also provides a stable foraging base for herbivores, detritivores, and secondary consumers (Thayer et al. 1984).

Suspended sediment is removed from the water column when the frictional drag of water flowing over the leaves and stems reduces water velocity and wave energy, allowing sediment to settle out of the water column. Roots bind and stabilize the substrate, partially inhibiting bottom sediments from being resuspended (Thayer et al. 1984; SAFMC 1998). This deposition enhances the productivity, stability, and biodiversity of SAV. The rhizomes and roots of SAV stabilize the substrate and form large pools of organic matter and structural matrices supporting many species that live in the sediment (Kenworthy and Thayer 1984). Particle deposition and burial, as well as formation of organic matter in the sediment, facilitate temporary and permanent retention of nutrients within SAV beds by the roots and rhizomes (Thayer et al. 1984; SAFMC 1998). These functions improve water quality down-current of the bed by removing suspended solids from the water column, improving water clarity, and adding dissolved oxygen. The presence of SAV is both a maintainer and indicator of good water quality (Virnstein and Morris 1996; R. Ferguson, NMFS, pers. com., 2000). *However, the exact relationship between the extent of SAV coverage and water quality is unknown and requires research.*

Seagrasses have a stabilizing effect on substrate and nearby shorelines by absorbing wave energy (Fonseca 1996a). By buffering nearshore turbulence, SAV beds reduce erosion along adjacent shorelines, which also helps stabilize marsh edge habitat (Stephan and Bigford 1997). Where water turbulence is too great for SAV to persist, its buffering capacity over time may be limited (Thayer et al. 1984). Although oyster reefs are relatively more resilient to turbulence than SAV beds, both oyster reefs and SAV beds provide, among other ecosystem functions, shoreline protection (Fonseca 1996a; Day et al. 1989).

Fish utilization

Many species occupy SAV at some point in their life cycle (Thayer et al. 1984). However, the importance of SAV depends on its relative contribution to a particular species' refuge, spawning, nursery, foraging, and corridor needs. For instance, some species use SAV directly as a food source (consumption of living plant material) while other species rely on SAV indirectly, by hunting for prey along the edge of the beds, or finding refuge from predation while foraging within the beds.

Submerged aquatic vegetation was classified as "Essential Fish Habitat" (EFH)[1] by the SAFMC (1998) due to its habitat heterogeneity, plant biomass, and surface area, all of which enhance animal abundances. Because of the different temporal abundance patterns in SAV species, feeding habitat and refuge for fish and shellfish are provided almost year-round for estuarine-dependent species (Steel 1991). In North Carolina, the species for which SAV is considered EFH include red drum; brown, white, and pink shrimp; and species in the snapper-grouper complex. While bay scallops are not managed by the SAFMC, the SAV habitat that bay scallops share with federally managed species is technically considered EFH (K. Abrams, NOAA, pers. com., 2003). Several important forage species also depend on SAV habitat. The two EFH categories for SAFMC-managed species are salt/brackish and freshwater SAV.

Salt/brackish grasses

In brackish and high salinity estuaries, fish and invertebrates use SAV, to varying extents, as nursery, refuge, foraging, and spawning locations. Studies in eelgrass beds in the Newport River estuary and vicinity reported between 39 and 56 fish species during regular monitoring conducted in the 1970s (Thayer et al. 1975; Adams 1976; Thayer et al. 1984). Results from DMF's juvenile fish sampling in

[1] EFH is defined by SAFMC as those waters and substrate necessary to fish for spawning breeding, feeding, or growth to maturity.

seagrass beds in eastern Pamlico and Core sounds found over 150 species of fish and invertebrates from 1984 to 1989, of which 34 fish and six invertebrate species were important commercial species (DMF 1990). Adult fish as well as juveniles utilize grass beds. Composition of long haul seine catches sampled by DMF reported at least 49 adult fish species collected over seagrass beds in eastern Pamlico Sound (DMF 1990). In addition to fish, over 70 benthic invertebrate species have been reported from eelgrass beds along the east coast (Thayer et al. 1984). Bay scallops occur almost exclusively in SAV beds (Thayer et al. 1984), and spotted seatrout (*Cynoscion nebulosus*), an important recreational and commercial species in North Carolina, is also highly dependent on the quantity and quality of SAV habitat (Vetter 1977). Species whose relative abundances at some life stage are generally higher in SAV than in other habitats, or otherwise show some preference for SAV, are referred to as "SAV-enhanced." A partial list of species utilizing SAV habitat in North Carolina is compiled in Table 4.5.

Several studies along the coasts of the Atlantic Ocean and the Gulf of Mexico have demonstrated significantly greater species richness and numerical abundance of organisms in seagrass beds compared to unvegetated bottom (Thayer et al. 1975; Summerson and Peterson 1984; Heck et al. 1989; Ross and Stevens 1992; Irlandi 1994; ASMFC 1997a; Wyda et al. 2002). In Back Sound, N.C., a study found that fish and shrimp were more abundant on artificial SAV beds than on shell bottom (Elis et al. 1996). In the Newport River estuary (Core/Bogue MU), rough silverside (*Membras martinica*) and smooth dogfish (*Mustelus canis*) were classified as abundant in SAV beds, but were rare or absent in marsh channel and intertidal flats (Thayer et al. 1984). Blue crabs and pink shrimp were significantly more abundant in SAV beds than in adjacent shallow non-vegetated estuarine bottoms in North Carolina, Alabama, and Florida (Williams et al. 1990; Murphey and Fonseca 1995). In the Chesapeake Bay region, juvenile crabs grow faster, occur more densely, and have higher survival rates in SAV beds (Heck and Orth 1980; Chesapeake Bay Commission 1997). In addition to natural fluctuations in SAV coverage and density, the utilization of SAV by fish and invertebrates differs spatially and temporally due to species distribution ranges, time of recruitment, and life histories (Nelson et al. 1991).

Some studies have shown a linkage between the abundance and species composition of fish and the quantity and quality of SAV. Abundance, biomass, and species richness of fish assemblages in two spatially distant areas of the Mid-Atlantic Bight (Buzzards Bay and Chesapeake Bay) were significantly higher at sites with higher levels of seagrass complexity (biomass >100 wet g/m^2; density >100 shoots/m^2) compared to sites with reduced seagrass complexity (Wyda et al. 2002).

Abundance, biomass, and species diversity at sites with reduced seagrass complexity were more variable than at sites with high seagrass complexity. Sites with lower SAV complexity also had a greater proportion of pelagic species than bottom, structure-oriented species. In Florida Bay, changes in animal abundances were compared between the 1980s and 1990s when significant changes in SAV coverage also occurred (Matheson et al. 1999). The major change observed was a decrease in abundance of small fish and invertebrates that live within the seagrass canopy (such as crustaceans and pipefish) with decreases in SAV coverage, while larger demersal predatory fish (such as toadfish and sharks) increased. Similarly, increases in SAV density were characterized by significant increases in crustaceans. In another study in Florida Bay, greater reductions in pink shrimp abundance occurred in seagrass die-off areas relative to adjacent undamaged or recovering areas (Roblee and DiDomenico 1992). In North Carolina, comparison of pink shrimp densities in continuous and patchy seagrass beds found significantly greater shrimp densities in continuous beds than in patchy grass beds (Murphey and Fonseca 1995). Although patchy seagrass beds did not support as great a density of shrimp, they still functioned as important habitat for pink shrimp (Murphey and Fonseca 1995). The presence of SAV may be the reason pink shrimp can overwinter and survive, supporting a spring pink shrimp fishery in North Carolina (T. Murphey, DMF, pers. com., 2003). The pink shrimp fishery comprises a large portion of North Carolina's annual shrimp landings. In contrast, in South Carolina and Georgia, where no SAV is present, pink shrimp comprise an extremely small portion of the shrimp landings. Similarly, survival of blue crabs in a New Jersey estuary was attributed to the ability of the species to overwinter in SAV (Wilson et al. 1990).

Table 4.5. Partial list of species documented to use submerged aquatic vegetation habitat[5].

[5] Names in bold font are species whose relative abundances have been reported in the literature as being generally higher in SAV than in other habitats. Note that lack of bolding does not imply non-selective use of the habitat, just a lack of information.

Freshwater grasses

In coastal riverine systems, such as the Chowan River, finfish, shellfish, and crustaceans utilize SAV as nursery areas for refuge and protection, particularly minnows, killifish, juvenile striped bass, largemouth bass, and molting/soft shelled blue crabs (Hurley 1990). Floating leaf aquatic vegetation is particularly important in freshwater systems such as the Roanoke River (Cooper et al. 1994). Freshwater SAV is also an important habitat for estuarine species, in streams and some lakes, such as Lake Mattamuskeet. Common species using freshwater SAV is shown below and in Table 4.5. *More research is needed to improve scientific understanding of the relationship of SAV to fresh and brackish water fish species.*

COMMON FISH SPECIES THAT UTILIZE FRESHWATER SAV
(Source: Rozas and Odum 1987; SAFMC 1998; NOAA 2001)

Freshwater species

In freshwater streams and lakes
sunfish
minnows
white perch
juvenile American eel
pirate perch
inland silversides
yellow perch
largemouth bass
bluegill sunfish

Estuarine species

In freshwater streams
juvenile menhaden
spot
blue crab
grass shrimp
bay anchovy

In freshwater lakes
striped mullet
tidewater silverside
white perch

Anadromous Species
striped bass
shad
river herring

Specific biological function

Refuge

The physical structure of SAV conceals prey from visual detection, restricts the pursuit and capture of prey by predators and protects small organisms from adverse weather conditions (Rooker et al. 1998, Savino and Stein 1989, SAFMC 1998). High densities of seagrass shoots and increased plant surface area inhibit predator efficiency and provide shelter to prey (Coen et al. 1981 for grass shrimp; Prescott 1990 for bay scallops; Orth 1992 for blue crabs). Moreover, the predation mortality rate of red drum in unvegetated habitat was up to four times greater than that observed in SAV habitat (Rooker et al. 1998). Light levels are reduced within the canopy as well, further concealing small prey (SAFMC 1998). In addition, cryptic species that have the ability to change color use camouflage to decrease their visibility within the SAV habitat.

Since beds of SAV can be as tall as one meter (3.28 ft), their leaf canopies provide a three-dimensional structure containing a large volume of sheltered water. The blades of SAV can increase the available surface area for colonization by an order of magnitude when compared to adjacent unvegetated habitats (SAFMC 1998). In the sediment, the roots and rhizomes of SAV also provide a matrix for meiofauna[2] and macrofauna [3](Kenworthy and Thayer 1984). Organisms utilize the leaves, roots, and rhizomes, as

[2] Very small benthic animal, 0.1 – 0.5 mm in size, about the size of a sand grain, important food source for larval fish
[3] Small benthic animal larger than 0.5 mm in size; ie., mole crabs, amphipods

well as the space between shoots, for refuge from predators and adverse environmental conditions (SAFMC 1998). Hard clams are significantly more abundant in SAV beds than in adjacent unvegetated bottom due to changes in food supply, predation, and sediment stability (Peterson and Peterson 1979; Peterson 1982; Irlandi 1994, 1996).

The refuge value of SAV also depends on its corresponding value for predators. For example, benthic macroinvertebrates can be more vulnerable to crab predation in SAV because crabs use SAV for refuge from avian predators (Skilleter 1994; Micheli and Peterson 1999; Beal 2000). Summerson and Peterson (1984) hypothesized that nocturnal bottom predators living on sand flats use SAV during the day to avoid their own predators. Predator–prey interactions in SAV habitat are a function of canopy structure, shoot and blade density, and surface area (SAFMC 1998).
Moreover, the relative value of SAV as refuge is also likely to change over time, not only with seasonal patterns of SAV abundance (Prescott 1990) but also during the course of the day. As previously mentioned, mobile epibenthic[4] organisms that typically hide from predators in seagrass beds during daylight may later feed and successfully avoid visually-searching predators on unvegetated flats under the cover of darkness (Summerson and Peterson 1984).

Spawning

Coastal aquatic species that spawn in SAV include blueback herring, mummichog, bay scallop, grass shrimp, and rough silversides (Stephan and Bigford 1997; NOAA 2001). The roots and stems of SAV also provide substrate for attachment of eggs and invertebrates (such as barnacles, sea squirts, and bryozoans). Seasonal patterns of reproduction and development of many temperate fishery species coincide with seasonal abundance of seagrass (Stephan and Bigford 1997). Estuarine-dependent spring-summer spawners utilize SAV habitat in the spring and summer for forage and refuge, residing there prior to emigrating to the mouths of bays and rivers, inlets, or coastal ocean shelf waters to spawn (SAFMC 1998; Luczkovich et al. 1999). Some of these species include red drum, weakfish, spotted sea trout, silver perch, and southern kingfish. *Additional research is needed on how SAV affects spawning success of these or other species.*

Nursery

Submerged aquatic vegetation is a primary nursery habitat for numerous species of fish and invertebrates along the Atlantic coast (Thayer et al. 1984). Important commercial and recreational species present in SAV as juveniles in the spring and early summer include gag, black sea bass, snappers, weakfish, bluefish, mullet, spot, Atlantic croaker, red drum, flounders, and herrings (SAFMC 1998). The roots and stems of SAV provide ideal protection and food for developing fish and invertebrate larvae (Ambrose and Irlandi 1992; SAFMC 1998). Larvae of spring-summer spawning fish (such as anchovies, gobies, pipefish, spotted seatrout, weakfish, hard clams and southern kingfish) use SAV habitat (SAFMC 1998). In North Carolina, where SAV is present year-round, some larval and early juvenile finfish, molluscan, and crustacean species are also present much of the year (SAFMC 1998). Both bay scallops and hard clams attach to seagrass blades temporarily before settling on the bottom (Thayer et al. 1984; SAFMC 1998). While hard clams also utilize other substrates, such as oysters and shell hash, bay scallops almost exclusively utilize seagrass, and are therefore highly dependent on its existence for successful recruitment[5] (Thayer et al. 1984; Stephan and Bigford 1997). Juvenile blue crabs prefer shallow water areas with structure, including SAV, tidal marsh, shell bottom and detritus (Etherington and Eggleston 2000). In the Albemarle – Pamlico system, the majority of initial recruitment occurs in seagrass beds around inlets behind the Outer Banks, unless there is a major storm event. In years with large storm events, crabs are dispersed into additional lower salinity habitats (Etherington and Eggleston 2000). At

[4] Organism that lives at the surface of the bottom, as opposed to burrowed below bottom; ie., starfish, flounder
[5] Successful settlement, and in some cases metamorphosis, of pelagic larvae into their juvenile habitat. Also refers to successful movement of juveniles into adult habitat or fishery.

sites near Ocracoke and Hatteras Inlets, the density of juvenile blue crabs increased significantly with increasing seagrass blade length, but not with biomass or shoot abundance (Etherington and Eggleston 2000). *More research is needed on the use of SAV for larval fish and invertebrate settlement and as a nursery; by determining optimal conditions for such species, additional success criteria may be developed for seagrass restoration projects.*

Several groups of fish use SAV as nursery habitat. Spot, croaker, shrimp, and pinfish are estuarine-dependent offshore spawners that inhabit SAV habitat as early juveniles in winter and early spring. Submerged aquatic vegetation has been recognized as critical nursery habitat for pink shrimp in North Carolina (Murphey and Fonseca 1995). Silver perch, spotted seatrout, and red drum are estuarine spawners, and their juveniles are present later in the spring and in the summer. Estuarine-dependent reef fish use seagrass meadows as juveniles, prior to moving offshore. For example, juvenile gag (*Mycteroperca microlepis*) use SAV habitat for refuge and foraging on crustaceans before moving to offshore hard bottom as a secondary nursery area (Ross and Moser 1995). Juvenile sheepshead (<50 mm or <2.17 in) and juvenile gray snapper also utilize SAV beds (Pattilo et al. 1997). However, juvenile gray snapper are rare in most interior waters of North Carolina, and they are common only in Pamlico Sound from July to November (Nelson et al. 1991).

Some studies have found that juvenile red drum, as well as pink shrimp and sand seatrout (*Cynoscion arenarius*) were more abundant in SAV beds compared to marsh edge, inner marsh, shell bottom, or shallow non-vegetated bottoms (Minello 1999); other studies disagree (Stunz et al. 2002). The degree of preference by red drum for SAV is somewhat uncertain since they also utilize estuaries lacking SAV, such as in the southern portion of North Carolina and South Carolina. However red drum eggs, larvae, postlarvae, and juveniles have been documented in SAV beds in North Carolina which is particularly important as a foraging area for young (1-2 year old) red drum (Mercer 1984; Reagan 1985; Ross and Stevens 1992). Abundance of juvenile red drum in SAV beds varies seasonally and spatially, being more common in grass beds during summer months and in grass beds that are close to spawning areas (Zieman 1982; DMF, unpub. data). Also, juvenile red drum were more abundant in edge habitat with patchy grass coverage than in homogeneously vegetated sites (Mercer 1984; Reagan 1985; Ross and Stevens 1992). Data from DMF red drum seine surveys and tagging studies indicate high abundance of late young of year red drum in shallow high salinity grass beds behind the Outer Banks (DMF 2001c). Rooker et al. (1998) also examined post-settlement patterns by several species in SAV habitat and found densities of red drum, spotted seatrout and silver perch were highest for very small individuals (4-8mm or 0.1 – 0.3 in). These fish utilized SAV habitat at smaller sizes and remained in SAV longer than spot and croaker. Spot and croaker seemed to utilize SAV habitat more as temporary residents, migrating to alternate habitats shortly after their arrival (Rooker et al. 1998).

Studies have shown that recruitment of small juvenile fishes corresponded to periods of greatest SAV coverage (SAFMC 1998). In freshwater SAV beds, Paller (1987) determined that the standing stock of larval fish was 160 times higher than in adjacent open waters, and that larvae would concentrate in the interior of aquatic beds rather than in the transition zones between habitats. This difference suggests that large SAV beds provide better refuge for larvae than an equivalent area of patchy SAV. Several studies in estuarine SAV beds also found that juvenile hard clams, pink shrimp, and blue crabs were more abundant in large or continuous SAV beds than in small or patchy SAV beds, whereas the opposite was found for adult pink shrimp and grass shrimp (Murphey and Fonseca 1995; Irlandi 1997; Eggleston 1998). This finding suggests that habitat fragmentation could have a significant impact on recruitment of some species.

Noble and Monroe (1991) analyzed environmental variables associated with relative abundance and diversity of juvenile finfish and crustacean from the DMF nursery area database for the Albemarle-Pamlico estuarine area. Critical habitat criteria, based on core group characterizations, were developed to better define and protect critical fishery habitats functioning as nursery areas for economically important

finfish and crustaceans. The study recommended classifying a "new type" of nursery area characterized by higher salinities, SAV presence, and a somewhat different species composition than the typical Albemarle-Pamlico Peninsula nursery areas (such as Rose Bay). *Criteria should be developed and implemented to assist with designation of SAV beds as Strategic Habitat Areas by the MFC.*

Foraging

Submerged aquatic vegetation supports numerous complex food webs and serves as a foraging area for fish and invertebrate species. Nutrient sources associated with SAV include, but are not limited to, dissolved organic matter, epibiota, plants and animals living on and in the sediment surrounding SAV rhizomes, and living SAV tissues (Adams and Angelovic 1970; Thayer et al. 1975; SAFMC 1998). The majority of organisms in SAV habitat utilize secondary production from epibiotic communities, benthic algae, organic detritus, and bacteria rather than direct consumption of SAV (Day 1967; Adams and Angelovic 1970; SAFMC 1998).

Benthic invertebrates (i.e., worms, snails) and fish graze on other benthic animals that live in the sediment among SAV roots and stems. These small invertebrates and fish, in turn, provide food for larger fish and shellfish adapted to feed upon them. Benthic algae are important forage items for pelagic-feeding planktivorous fishes (such as silversides) that inhabit the grass beds at night (Meyer 1982). Eelgrass and shoalgrass are highly productive (Thayer et al. 1984), and their stems and leaves provide an important substrate for attachment by small organisms that contribute to the overall productivity of the system and serve as forage for larger organisms (Carr and Adams 1973).

Only a few fish species are known to consume submerged grasses directly. These include pinfish (*Lagodon rhomboides*), spot (*Leiostomus zanthurus*), filefish (*Monocanthus hispidus*), and toadfish (*Opsanus tau*). However, SAV comprised only 1 – 12% of their diet (Thayer et al. 1984). Rather than direct grazing, most fish and invertebrates benefit from SAV indirectly by foraging on small plants and animals associated with the vegetation. In contrast, many species of birds (e.g., black brant, *Branta bernicla;* Canada goose, *Branta canadensis,* and widgeon, *Anas penelope*) graze directly on freshwater SAV. The green sea turtle and West Indian manatee consume salt/brackish SAV (SAFMC 1998). Green turtles appear to be more abundant in seagrass than in unvegetated areas in North Carolina, based on data from incidental occurrence in pound nets (SAFMC 1998). Abundant green turtles closely crop seagrass and greatly reduce the input of organic matter and nutrients to sediments (Jackson et al. 2001). An absence of SAV grazers can result in excessive growth and accumulation of substrate suitable for proliferation of slime mold, which is largely responsible for SAV wasting disease (see Threats section, below) (Jackson et al. 2001).

Fisheries production by SAV results primarily from predator consumption of the plants and animals that live on the seagrass (leaves and roots/rhizomes), benthic algae, and organic detritus (SAFMC 1998). Large predatory fish such as Atlantic stingrays, flounders, bluefish, sandbar and other sharks, weakfish, red drum, spotted seatrout, and blue crabs eat small fish, crustaceans and invertebrates that live in seagrass beds (Thayer et al. 1984). Although large finfish predators represent only a small proportion of the fish biomass in SAV habitat, they can be important in structuring seagrass communities and, at times, can uproot grasses or alter the substrate (e.g., cownose ray; Orth 1975).

Corridor and connectivity

For some species, such as blue crabs, SAV can function as a safe corridor between habitats reducing predation (Micheli and Peterson 1999). In marshes where adjacent SAV was removed, the abundance of grass shrimp declined 27% and was significantly higher where SAV was not removed (Rozas and Odum 1987). Submerged aquatic vegetation adjacent to marshes also provides a refuge at low tide for organisms associated with marsh edge habitat at high tide (Rozas and Odum 1987). Consequently, the catch of fish was also higher at sites with both marsh and SAV, rather than just marsh. In a North

Carolina estuary where SAV occurred adjacent to intertidal marsh, pinfish showed more movement, were more abundant, and weighed more than those in areas where SAV was not present adjacent to the marsh edge, indicating that SAV provided a safe passage and offered additional food resources (Irlandi and Crawford 1997). Similarly, another study in North Carolina found that adult fish abundances were greater where marsh, seagrass, and oyster reefs co-occurred, rather than areas with shell bottom alone or shell bottom with marsh (Grabowski et al. 2000). The corridor function of SAV may also apply to other small predators that are more susceptible to predation in open water. Although red drum have a strong association with marsh edge habitat in Gulf coast estuaries (Minello 1999; Stunz et al. 2002), information is lacking for North Carolina. *Examination of the relationship between juvenile red drum abundance in SAV and marsh edge habitat and the effect of spatial connectivity on habitat use should be conducted to support management of this important species.*

4.3. STATUS AND TRENDS

Status of submerged aquatic vegetation habitat

When SAV beds are subjected to human-induced impacts in addition to natural stressors, large-scale losses of SAV may occur (Fonseca et al. 1998). Such losses of seagrass beds have been as high as 50% in Tampa Bay, 43% in northern Biscayne Bay, and 30% in the northern portion of Indian River Lagoon (all in Florida), and as much as 90% in Galveston Bay, Texas, and Chesapeake Bay (Taylor and Saloman 1968; Kemp et al. 1983; Pulich and White 1991; Smith 1998). In North Carolina, SAV loss has not been quantified, but anecdotal reports indicate that the extent of SAV may have been reduced by as much as 50%, primarily from the mainland side of the coastal sounds (J. Hawkins, DME, pers. com., 2003; B.J. Copeland, MFC, pers. com., 2003; North Carolina Sea Grant 1997). However, since low-salinity SAV tends to exhibit large fluctuations from year to year, and because no mapping has been conducted to quantify the reported SAV changes, the extent of loss is uncertain.

In North Carolina, data on trends in SAV distribution are limited to qualitative information or only certain areas of the coast. For example, while SAV currently is concentrated along the sound side of the Outer Banks (Ferguson et al. 1989), elderly fishermen and fishermen's journal accounts from the late 1800s describe extensive beds of SAV in many coves along the mainland where it is absent today (Mallin et al. 2000). Seagrass wasting disease devastated eelgrass populations throughout the North Atlantic, including North Carolina, between 1930 and 1933, dramatically disrupting estuarine systems. Higher water temperatures apparently stressed the seagrasses, making them more susceptible to the slime mold protist *Labryinthula* (Steel 1991). Healthy eelgrass beds were generally re-established by the 1960s. Some specific information on SAV changes in Currituck Sound and the Tar-Pamlico and Neuse rivers is given below and is depicted in Table 4-6.

DRAFT

Table 4.6. Timeline of major trends in abundance of submerged aquatic vegetation (SAV) in North Carolina estuaries. *[Source: Davis and Brinson 1983; Steel 1991]*

Year	Changes in submerged aquatic vegetation in coastal North Carolina
1918 - 1919	Major decline in Currituck Sound due to turbidity from opening Albemarle and Chesapeake Canal
1930	Major decline in eelgrass in Pamlico, Core, and Bogue sounds from seagrass wasting disease
1952	Full recovery in Currituck Sound from improved management of canal locks
1955	Four hurricanes cause major loss to SAV in Currituck Sound but it recovers within two years
1960	Eelgrass in Pamlico, Core, and Bogue sounds mostly recovered from seagrass wasting disease
1962	Decline in native freshwater species in Currituck Sound due to saltwater intrusion and displacement by non-native Eurasian watermilfoil
1975	SAV common in upper Pamlico River estuary
1985	Significant declines in SAV in upper Pamlico River estuary (1% of pre-1970s levels), western Pamlico Sound, and Neuse River estuary due to excessive sediment loading
1990	Improved erosion control methods and/or weather patterns result in slight recovery of SAV in Neuse and Pamlico estuaries
2002	Reports of increased SAV in Albemarle Sound, possibly due to drought conditions improving water clarity

Currituck Sound has a significant historical record of observations and/or biomass of brackish water SAV (Davis and Brinson 1983). Studies have documented the status of SAV in Currituck Sound since 1909, including a major decline around 1918 attributed principally to increased turbidity (Bourn 1932; Davis and Brinson 1983). The locks of the Albemarle and Chesapeake Canal were opened during this period (Davis and Brinson 1983). This canal connects the Norfolk (Virginia) Harbor at the mouth of the Chesapeake Bay with Currituck Sound by way of the North Landing River. From 1914 to 1918 the canal was deepened and widened, and the North Landing River was dredged extensively. In 1932, operation of the canal locks was modified, improving the situation, and the SAV began to recover. Submerged vegetation had fully recovered by 1951, with the highest production of submerged aquatic plants in the Currituck-Back Bay system since 1918 (Davis and Brinson 1983). During 1954 and 1955, the occurrence of four hurricanes along the North Carolina coast increased turbidities via sediment suspension and resulted in widespread destruction of plant beds (Dickson 1958). Submerged vegetation in other hurricane-impacted areas of North Carolina may have been similarly affected. However, the SAV community recovered rapidly, as growth was considered good in 1957 (Davis and Brinson 1983). After a severe nor'easter storm in 1962, saltwater intrusion in the sound raised the average salinity slightly (4.4 ppt) and caused major reductions in freshwater SAV biomass (Davis and Brinson 1983). Another factor contributing to reductions in northern Currituck Sound was likely the accumulation of silty, semiliquid dredge spoil in the North Landing River and the resulting turbidity (Davis and Brinson 1983).

As the native SAV beds recovered after 1962, Eurasian watermilfoil (a non-native species) began to spread across Currituck Sound from its northern extremities (Davis and Brinson 1983). The spread of the exotic plant was probably encouraged by improved water clarity caused by dry conditions and higher salinities after 1962 (Davis and Brinson 1983). Before 1962, native sago pondweed and wild celery were the dominant and subdominant SAV species (Davis and Brinson 1983). By 1973, Eurasian watermilfoil had replaced sago pondweed as the dominated aquatic plant species, followed by bushy pondweed (Davis and Brinson 1983). After a severe storm in 1978, bushy pondweed was virtually eliminated, and total

macrophyte biomass was 42% less than in 1973 (Davis and Brinson 1983). Again, the reductions in SAV biomass were associated with extreme turbidity and turbulence associated with the severe weather during the early growing season in 1978. It is apparent from this historical record that SAV coverage and biomass are greatly affected by weather events, site conditions, and human activities that affect turbidity and salinity. This relationship is true not only for Currituck Sound, but also for other coastal water bodies containing SAV.

In the upstream half of the Pamlico River estuary, SAV was common until the mid-1970s (Davis and Brinson 1976; Davis and Brinson 1989). By 1985, SAV biomass had been reduced to about 1% of its pre-1970s biomass (Davis and Brinson 1989). Tidal freshwater SAV (primarily wild celery) was historically abundant in western Pamlico Sound (Copeland et al. 1984), and to a lesser extent, the Neuse River, with pondweeds (*Potamogeton* spp.) and widgeon grass also common (Steel 1991). Submerged aquatic vegetation in these areas declined significantly during the mid-1980s, under excessive sediment loading, and then experienced a resurgence as modest improvements in erosion control promoted an increase in water clarity (Mallin et al. 2000). This information is derived mostly from many recent complaints about abundant SAV around dock areas (Neuse) and from visual observations and fishermen's anecdotal accounts (Pamlico) (Mallin et al. 2000). *The status of SAV in western Pamlico Sound and its tributaries should be confirmed by regular mapping efforts, ideally with an experimental design that will allow inference regarding the cause of any observed changes.*

In 1998 presence and distribution of SAV in the Neuse River estuary was assessed by DWQ, in coordination with NMFS and EPA using aerial photography and field ground-truthing (DWQ 1998). The study area extended from the N.C. Highway 43 bridge north of New Bern downstream to Rattan Bay where the river opens to Pamlico Sound, about 48 river miles (77.25 km). Distribution of SAV in the Neuse River estuary is shown in Maps 4.3a and 4.3b. Eleven species of SAV were documented at the sample sites. The SAV occurred in multiple small patches along both the north and south shorelines of the Neuse River and its tributaries in water depths ranging from 0.5 to 1.4 m (1.64 – 4.59 ft). Roughly 514 acres (208.01 ha) of SAV were delineated. North of New Bern, *Nuphar lutea* was the prevalent species found. In the middle of the river, where most SAV occurred, coontail or hornwort (*Ceratophyllum* sp.) was the most common species, followed by wild celery. The largest patch of SAV occurred on the south shore of the river, downstream of the mouth of the Trent River. This large patch was dominated by wild celery. In the lower portion of the river, widgeon grass was most common. Results showed that SAV was present at four of five areas that had supported SAV in 1991, indicating there has not been a major decline in SAV abundance over the seven-year period on the Neuse. More SAV was identified in 1998 than in 1991. However, because of the different methodologies used, change in coverage can not be accurately assessed.

Some recent, unquantified changes have been noted in SAV distribution and abundance in the Albemarle Sound area and Bogue Sound. Several large eelgrass beds have disappeared in the Intracoastal Waterway in the Morehead City area (Core/Bogue MU) following intensive use of herbicides to control macroalgal growth over the last ten years (Mallin et al. 2000). Over that same time period, large SAV beds near Harkers Island (Core/Bogue MU) have also disappeared following construction activity (unpub. data cited in Mallin et al. 2000). In 1988, the shallow waters of Perquimans River were overgrown with dense stands of Eurasian watermilfoil and other species (Steel 1991) (Map 4.2). After Hurricane Floyd in 1999, those dense stands of milfoil had disappeared. Local commercial fishermen reported that the blue crabs had disappeared along with the grass. In 2002, DMF biologists noted high abundance of SAV throughout many shallow water areas of Albemarle Sound and its tributaries, especially in Perquimans River (S. Winslow, DMF, pers. com., 2002). The SAV was reportedly spreading upstream from the lower reaches of the rivers, near the main body of Albemarle Sound. *Research is needed to verify if a recovery of SAV has occurred and to determine if there is a spatial pattern of that recovery. If there is a pattern, special monitoring and protection should be afforded to those core areas from which SAV begins its recolonization.*

Coast wide aerial photography of SAV combined with on-site sampling is the standard method for mapping SAV in coastal North Carolina and Chesapeake Bay. The method was last used in North Carolina in the late 1980s to early 1990s (Ferguson and Wood 1994). Regular aerial photography and mapping of the coastal area would provide the necessary information to determine status and trends in SAV distribution, coverage, and health over the long-term. *Coast-wide mapping should be repeated at regular intervals using similar methodology to the early 1990s mapping to determine the current location and quantity of SAV coverage and compare changes over time. In addition to maps of current SAV coverage, a comprehensive map of all potential SAV habitat should also be developed.*

A process to calculate relative wave exposure indices has been completed by NMFS for Core and Back sounds. This process allows identification of areas that have physical characteristics, such as water depth, wave exposure, and currents, that are suitable for SAV colonization; which could include SAV habitat. *This process should be conducted in other areas of the coast to identify potential restoration sites for SAV.*

Status of associated fishery stocks

Inadequate data are available to assess if trends in SAV-enhanced fishery species are related to changes in SAV coverage. Of the species identified in Table 4.5 with a preference for SAV habitat, fourteen species were evaluated for fishery status. The hard clam was given an "unknown" status. Of the remaining thirteen stocks with a designated status, two were designated Overfished (15%), four were Concern (31%), one was Recovering (8%), and six were Viable (46%) (SAFMC 2002; DMF 2003; Figure 4.1). Specifically, sheepshead and tautog were listed as "overfished." The SAV-enhanced stocks given a Concern status included bay scallop, blue crab, Atlantic croaker, and striped mullet. Viable and Recovering stocks included red drum, spotted seatrout, weakfish, shrimp, gag, summer flounder, and gray snapper. Whereas much of the cause of declining stock status is attributed to overfishing, habitat loss and degradation can make a stock more susceptible to overfishing. Therefore, protection or enhancement of SAV habitat can be especially beneficial to SAV-enhanced species classified as Overfished or Concern, by maximizing recruitment and productivity.

Trends in fishery data indicate a decline in catch and effort for some prominent SAV-enhanced species. Landings data for bay scallops indicate a long-term decline in catch and effort (Figure 4.2). However, landings and fishery independent sampling indicated that this annual stock showed improved recruitment in Core and Bogue sounds in 2002 (DMF, unpub. data). Blue crabs also appear to be experiencing long-term declines in catch and effort, and possibly reduced abundance in some regions. More fishery-independent information and habitat change analysis are needed to determine the effect of SAV-coverage on the abundance of fish and invertebrates. *To obtain needed information on use and trends of fish utilization in SAV habitat, DMF staff should assess where additional juvenile fish sampling stations are needed and add these to existing sampling programs. Research should be conducted to better assess the relationships of bay scallop and blue crab to SAV and to investigate if long-term declining trends in these fisheries are related to declines in or degradation of SAV.*[6]

[6] Relationships can be generally inferred from habitat studies, which are covered in the Ecological role and function section.

Submerged aquatic vegetation restoration

Although protection, rather than mitigation or restoration, is the more environmentally sound and less costly management approach for long-term enhancement of SAV fisheries habitat (SAFMC 1998), restoration of SAV beds in areas that historically supported this habitat is possible to offset past losses. Seagrass restoration techniques have been developed and evaluated by the NMFS. Depending on environmental variables, a similar faunal community can return, at the earliest, within two years (Fonseca et al. 1998). The success of replanting efforts is often gauged by an evaluation of "functional equivalency." As defined by Fonseca et al. (1998), an area has achieved functional equivalency when "a restored or mitigated system attains [ecological] functions the same as those of an unimpacted system in a similar setting." According to the authors, an impacted seagrass bed has the potential to become functionally equivalent, but not identical, to an undisturbed seagrass bed if, a) it is at least equal in space to that of the original area prior to disturbance and b) the seagrass species composition is unchanged and persists after the disturbance. Based on review by Fonseca et al. (1998), the time needed to attain functional equivalency for seagrasses ranges dramatically, from less than 2 to more than 31 years. Seagrass shoot densities and canopy height can be used to determine when a restoration project has reached functional equivalency (Fonseca et al. 1998). Studies in Florida have found that SAV shoot densities approximately one third as dense as a natural bed supported similar animal densities (Fonseca 1996a; Fonseca 1996b). In North Carolina, beds having 30-40% SAV coverage had penaeid shrimp densities virtually indistinguishable from beds with continuous cover (Murphey and Fonseca 1995). The size of the restored SAV bed can also affect fish utilization. Some organisms, such as larval fish, juvenile blue crabs, and juvenile hard clams were more abundant in large, contiguous beds than in smaller, patchy beds (Paller 1987; Irlandi 1997; Eggleston et al. 1998). However, even SAV habitats as small as 1-2 m^2

have significantly greater numbers of fish, shrimp, and crabs than found in adjacent sand areas (Fonseca et al. 1998).

Reference materials discussing planting techniques emerged prior to and during the 1970s, but major attention and financial support to study seagrass restoration did not develop until the early 1990s (Fonseca et al. 1998). Prior to that time, the variable track records of SAV mitigation projects, many of which were unpublished or not subject to peer review, discouraged its establishment as a management tool, even though suitable planting methods were available (Fonseca et al. 1998). There have been both failures and successes in seagrass planting (Stein 1984; Thayer et al. 1985). If SAV is not present in an area because of water quality conditions (e.g., insufficient light, excess nutrients), establishment of planted submerged grasses, without improving water quality, is likely to be unsuccessful. Furthermore, EPA (2000) stated that water quality conditions needed to restore underwater grasses are likely to be more stringent than conditions needed to support existing healthy SAV beds. Maintenance of existing beds should, therefore, be a higher priority than restoration. In order to maintain existing SAV habitat, more stringent water quality standards need to be established in those areas. [7]

Restoration of submerged aquatic vegetation is generally conducted for compensatory mitigation, mitigation banking, or research purposes. Benefits of SAV restoration include fish habitat enhancement, sediment and shoreline stabilization, and water quality enhancement. Compensatory mitigation is the replacement of a natural resource, such as a bed of SAV destroyed or severely degraded by a permitted action. Such replacement is often required by the enforcement of Section 404 of the Clean Water Act by the U.S. Army Corps of Engineers (COE) or by State regulations enforced by other regulatory agencies (DCM, DWQ). The intent is replacement of ecological functions such as water quality, habitat, and hydrology. Mitigation is usually also meant to replace an acreage equal to or greater than that which was lost or impacted (<http://dcm2.enr.state.nc.us >, May 2002). Based on data available through the Internet on SAV restoration and mitigation (<http://dcm2.enr.state.nc.us/ims/restsites/srchall.htm>, May 2002), there were 12 SAV restoration projects in Carteret and two in Onslow counties between 1978 and 1991. Of these 14 sites, 11 were considered "successful".

Specifically, "success criteria" are identified by DCM as "those conditions which must be met for a mitigation site to be considered successful in order to receive a permit to impact those wetlands…[and the criteria] may include any combination of the following and often include all of the following: vegetation establishment, wildlife use and a hydrologic regime that is characteristic of the target wetland type" (<http://dcm2.enr.state.nc.us/Wetlands/defs.htm#habitat type>, Spring 2004). Three projects were done as North Carolina Department of Transportation (DOT) mitigation, and the remainder were research projects conducted by NMFS. A total of 1.95 acres (0.79 ha) of bottom were restored to SAV by these projects. This area is relatively small compared to restored shell bottom areas. Seagrass restoration projects tend to be more limited due to the relatively high water quality conditions needed for survival of the plants. *Restoration goals for SAV habitat should be established, including goals for SAV acreage, abundance, and species diversity, considering historical distribution and estimates of potential habitat. However, protection of existing SAV beds should be given a high priority.*

4.4. THREATS AND MANAGEMENT NEEDS

The distribution and quality of submerged aquatic vegetation may be negatively impacted by natural events and anthropogenic activities. Natural events may include regional shifts in salinity because of drought or excessive rainfall, animal foraging, storm events, cold temperatures or disease.[8] Anthropogenic activities can be broken into two basic categories: physical and water quality. Submerged aquatic vegetation is extremely susceptible to physical disturbance because of its vulnerable location in

[7] This approach is discussed in the water quality threats section.
[8] Changes in SAV coverage due to changing salinity patterns were discussed in the Status and Trends section.

shallow nearshore waters. Physical threats can negatively affect SAV by inflicting damage or mortality directly, as well as by indirectly influencing future survival, reproduction or establishment through alteration of preferred conditions (e.g., increased turbidity via bottom sediment resuspension). SAV is vulnerable to water quality degradation, and in particular to sedimentation, primarily because of its relatively high light requirements (Fonseca et al. 1998). Moreover, the timing of anthropogenic impacts can have important ramifications for SAV. For example, disturbances that remove eelgrass and their surrounding sediment during the summer and fall months may have the added consequences of eliminating the seed bank that will produce future season's plants and of reducing genetic diversity (P. Biber, NMFS, pers. com., 2003). Anthropogenic impacts to SAV habitat have been documented and summarized by the ASMFC (ASMFC 1997a), the Chesapeake Bay Program (1995), NMFS (Thayer et al. 1984; Fonseca et al. 1998), and others. Much of the information on threats is from these sources.

Physical threats

Channel dredging

Dredging and filling activities were at one time considered to have the greatest detrimental impact on SAV (Thayer et al. 1984). Dredging for creation or maintenance of navigational channels and inlets resulted in removal or destruction of existing grass beds. The change in bottom depth, bottom sediment characteristics, and water clarity that accompanies dredged channels prevents or discourages future growth or establishment of SAV (Stevenson and Confer 1978; Funderburk et al. 1991). SAV habitat can be destroyed if dredged material is placed directly on existing SAV. Potential SAV habitat can also be eliminated if unvegetated soft bottom is filled and converted to an upland spoil island, or dredged to an excessive water depth. The increased water depth in dredged channels reduces light penetration to the bottom, limiting the ability of SAV to colonize the area. In addition, dredged channels tend to refill with finer sediments (Thayer et al. 1984; Bishof and Kent 1990), which are easily resuspended by currents or boat wakes. The resulting chronic elevated turbidity and sedimentation can reduce light penetration to levels that reduce or eliminate productivity of adjacent grass beds and make colonization of unvegetated areas difficult (Thayer et al. 1984). Turbidity from dredging of fine sediments, such as mud bottom, is usually more severe and persistent than dredging of coarse sand bottom.[9]

Loss of SAV habitat from dredge and fill activities has been particularly severe in bays with major ports or metropolitan areas, such as Tampa Bay, Galveston Bay, and Chesapeake Bay (Taylor and Saloman 1968; Thayer et al. 1984). North Carolina's ports in Wilmington and Morehead City are small in comparison. No SAV occurs in the vicinity of the Wilmington port. In contrast, considerable SAV loss may have occurred in Morehead City when the port's turning basins and access channels were originally dredged, given that nearby, similar yet undredged areas within Bogue sound support SAV. Maps 4.5a-b show the location of the ports, navigational channels and marinas in coastal North Carolina and their proximity to SAV. Because almost all of the eastern shoreline of Core Sound and the southern shoreline of Back Sound are undeveloped (Shackleford and Core banks), the grass beds in that area have not been highly impacted by channel dredging, marinas, or docks.

Current state and federal regulations minimize impacts to SAV from permitted dredge and fill activities, particularly those associated with private development, and have reduced the severity of this threat (SAFMC 1998). Although dredging is currently prohibited in SAV beds, maintenance excavation "essential to maintain a traditional and established use" is approved if four criteria are met [15A NCAC 07H .0208]: "(i) the applicant demonstrates and documents that a water-dependent need exists for the excavation; (ii) there exists a previously permitted channel which was constructed or maintained under permits issued by the State or Federal government (if a natural channel was in use, or if a human-made channel was constructed before permitting was necessary, there shall be clear evidence that the channel was continuously used for a specific purpose); (iii) excavated material can be removed and placed in an

[9] Refer to the "Habitat Requirements" section for the light and sediment conditions needed for SAV colonization)

approved disposal area without significantly impacting adjacent nursery areas and beds of submerged aquatic vegetation; (iv) the original depth and width of a human-made or natural channel will not be increased to allow a new or expanded use of the channel."

The COE maintains 6,992 acres (2,829.56 ha) of navigation channels in coastal North Carolina (COE, unpub. data). Some of these channels may be adjacent to or bisect SAV occurrence (Maps 4.5a-b). New public dredging projects that could potentially impact SAV continue to be proposed. For example, relocation of a ferry landing at the north end of Ocracoke Island might require dredging a new access channel through seagrass. Realignment of an existing navigational channel through Bogue Inlet as part of the Emerald Isle beach nourishment project could destroy existing SAV habitat directly and indirectly through changes in scouring patterns of inlet currents. Alternative proposals often require weighing the impact of one habitat versus another. As the coast becomes more developed, additional projects involving SAV impacts are likely to occur. *The DMF and MFC should use existing permit review authorities and CRC and EMC should provide more protection to SAV within existing permitting authority to prevent or limit as much as possible direct or indirect impacts to SAV from all dredge and fill projects.*

Infrastructure

Other public works projects that can impact SAV include placement of infrastructure, such as bridge supports and fiber optic cables, on submerged lands. Bridge construction and replacement have resulted in SAV loss in several areas of Florida (Fonseca et al. 1998). In North Carolina two bridge projects on the Outer Banks could result in SAV loss. Replacement of the Oregon Inlet bridge with a new bridge and extended causeway behind Pea Island could cause direct impacts to the grass beds west and south of the current bridge, as well as indirect impacts from changing current patterns and scouring. Also, a new bridge is proposed to cross the middle of Currituck Sound. The proposed location is in the vicinity of the largest concentration of SAV in Currituck Sound, but the project is in the early stages of development and could change substantially. Laying of fiber optic cables across submerged bottom can also damage SAV where trench excavation is used (Nero 2001).[10] Impacts to SAV can be minimized by use of directional drilling technology. This method involves drilling a small tunnel under the seafloor instead of dredging a trench from the seafloor surface. *Infrastructure projects that require SAV impacts should be avoided. Where impacts are unavoidable, SAV losses should be minimized and adequately compensated through mitigation, using methods recommended by NMFS for SAV restoration or creation. Such projects should be monitored over time to determine persistence of restored SAV beds.*

Boating activity

Direct physical impacts from propeller scarring, vessel wakes, and mooring scars have recently been identified nationally as a major and growing source of SAV loss (Sargent et al. 1995; Fonseca et al. 1998; ASMFC 1997a). Propeller scarring of SAV occurs when outboard vessels travel through water that is shallower than the draft of the boat. The propeller cuts the plants' leaves, roots, and stems, as well as creates a narrow trench through the sediment. The damaged area is referred to as a "prop scar" (Sargent et al. 1995). A "blow hole" may also be excavated where boaters attempt to rapidly power off the shallow bottom (Kenworthy et al. 2000). Mechanical disturbance to sediments damages the plant's rhizomes, which reduces plant abundance and cover for extensive periods of time, sometimes for many years. Recovery of SAV can take anywhere from 2 to 10 years, depending on the SAV species and local conditions, or in some cases, the habitat may never recover (Zieman 1976; ASMFC 2000). Once started, SAV damage can increase beyond the initial footprint of the prop scar due to physical scouring by tidal currents, storms, or biological disturbance such as crab and ray burrowing (Patriquin 1975; Townsend and Fonseca 1998). As long as the affected areas are unvegetated, their ecological value is reduced (Fonseca et al. 1998).

[10] More information on the use of fiber optic cables in fish habitats is included in the hard bottom chapter of the CHPP

In some areas, particularly in Florida, watercraft have severely scarred seagrass beds (Sargent et al. 1995). Prop scarring was identified as an increasing problem in some areas of Chesapeake Bay as well (Funderburk et al. 1991). In both locations, increasing occurrence of prop scarring was associated with an increasing human population, as well as an increasing number of registered vessels (Hurley 1990; Sargent et al. 1995). Preliminary aerial observations of high salinity grass flats in North Carolina indicate that damage to SAV from propeller scarring is currently not a significant problem. However, as the human population along North Carolina's coast increases, so will the number of boats. From 1990 to 2000, the permanent population of Dare County, which borders most of the high salinity SAV in Pamlico Sound, increased by 31%, while the population of Carteret County, bordering Core and Bogue sounds, increased by 13% (Table 1.2). In addition, the seasonal (summer) population in barrier island municipalities jumped three to as much as 53 times more than the permanent population in 2000 (Table 1.3). Many of the seasonal visitors are also recreational boaters. The permanent population adjacent to waters with low salinity SAV has also increased at varying rates. Along the western shore of Pamlico Sound, population increased 12% in Craven County, 14% in Pamlico County, and 6% in Beaufort County. In northeastern North Carolina, the permanent population of Currituck County grew by 32%, while the counties along tributaries of Albemarle Sound increased by 7-16%. During this same time period, the number of registered boats in North Carolina increased by about 40% (Figure 4.3). As the number of boaters in North Carolina continues to increase, the potential for damage to SAV via prop scarring is likely to increase, as has happened in Florida and Virginia. *Educational outreach is needed to increase awareness by the boating public of the ecological value of SAV and the damaging effects of boat propellers to SAV habitat. The level of damage to SAV from prop scarring should be assessed periodically. In areas where boating activity is found to cause significant SAV impacts, navigational markers should be installed to clearly delineate navigational channels to be used or SAV beds to avoid.*

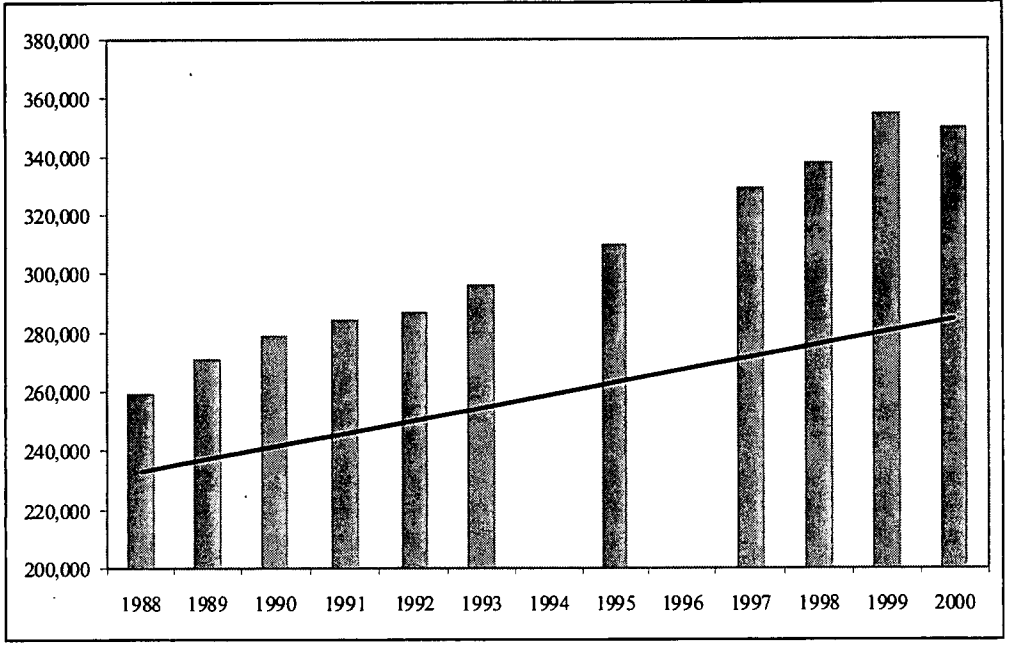

Figure 4.3. Total number of registered boats in North Carolina. *[Source: C. Murphey, North Carolina WRC, 2001]*

Marinas and docks

Marinas and docks impact SAV in several ways. During construction, placement of pilings or dredging of basins may destroy SAV. Once dredged, boat basins, like navigational channels, reduce light availability at the seafloor because of the increased depth, or change the sediment composition so that SAV cannot survive or recruit into the area (Stevenson and Confer 1978). Shoreline hardening structures associated with docking facilities (bulkheads) impact SAV by increasing wave energy and scour along the shoreline where SAV may occur, and by reducing shallow water habitat where SAV exists or could potentially colonize (Funderburk et al. 1991).

Shading from docks also results in loss of SAV beneath the dock structures. In a study in the Indian River Lagoon, Florida, light availability was reduced under docks that were 3 ft (0.91 m) and 5 ft (1.52 m) high to 11 and 14% of ambient light, which is less than the minimum amount needed (15-25%) for growth and survival of seagrass (Beal and Schmit 1998). Light availability increased with increasing dock elevation, and was significantly greater under the higher dock (5 ft or 1.52 m). The Florida Department of Environmental Protection (unpub. data) assessed the impact of dock shading to SAV in Palm Beach County, Florida, and found that 45% of surveyed docks had SAV around them but no SAV under them. Shading effects extended 1–3 m (3.28 - 9.84 ft) to either side of the docks. Seagrass presence was strongly correlated with dock height for docks ranging from 0–5.5 ft (1.68 m) above mean high water (MHW). Other studies in Florida found significantly less SAV under docks than in adjacent unshaded areas (Loflin 1995), and no seagrasses under docks having light levels less than 14% of surface irradiance (Shafer 1995). Offshore mooring of boats for extended periods of time in one location has also been shown to result in SAV loss in a circular area beneath the boat due to shading or damage from anchor and chain movement (Fonseca et al. 1998). These small individual losses of SAV may seem insignificant, but they can have significant cumulative impacts. The location of marinas and public boat access areas relative to SAV is depicted in Maps 4.5a-b.

In addition to direct damage from docks and marinas, indirect damage to SAV can result from boating activity associated with these structures. Shoals and other shallow bottoms supporting SAV may become scarred as boating activity to and from the docking areas increases. Boat wakes can destabilize and erode SAV beds, or resuspend sediment, reducing light penetration. As additional docks and marinas are constructed along the coast, the potential for boating-related damage increases. Based on marina records from DCM and SAV distribution maps, there are at least 104 marinas within 0.5 mi (0.81 km) of mapped SAV beds (Maps 4.5a-b). *Direct, indirect, and cumulative impacts to SAV and other habitats from marina and dock siting should be minimized. Development of a comprehensive state marina policy is needed to achieve this objective.*

Along the southeast coast of Florida, there are stringent standards for dock construction to minimize impacts to SAV. In John Pennekamp Coral Reef State Park in the Florida Keys, docks are prohibited over park bottom because of the documented impacts to SAV from construction, shading, and boating activity associated with the docks (R. Skinner, F.L. Park Service, pers. com., 2002). In other areas, the total square footage, width, or minimum height is limited. In aquatic preserves, guidelines for dock construction at one time required that access piers be five feet (1.52 m) above MHW with half inch (1.27 cm) deck spacing to allow more light to reach beneath the structure (Beal 1999). A minimum water depth of four feet (1.22 m) Mean low water (MLW) at the dock end is required in most areas, and in some areas, a dock may not be permitted if deep water access is not available (minimum of 4 ft [1.22 m] water depth MLW from dock to offshore waters).

In North Carolina, the depth of water at the dock end is not considered in CRC rules. With some exceptions, dock length is limited to no more than 25% of a water body's width, and cannot extend into navigation channels and should not extend beyond the length of other piers along the same shoreline. To minimize shading effects to wetland plants, CRC rules require a dock height of at least three feet (0.91 m)

above the wetland substrate, and a pier width of no greater than six feet (1.83 m) (CRC rule 15A NCAC 07H.0208 (6)). However, there is no requirement for height above the water surface. Total shading of the bottom by piers and docks is limited by a requirement that pier surface area associated with a given waterfront lot may not exceed a combined total area of four square feet per linear foot of adjacent shoreline. *Research is needed to determine if adequate light is available beneath North Carolina docks, given the current CRC dock siting criteria. These criteria should be evaluated to determine if existing requirements are adequate for SAV survival and growth and what changes would be needed to allow at least the minimum amount of light beneath docks. The permit requirements for docks and piers may need to be changed accordingly.*

The cumulative impacts from dock structures in rapidly developing coastal subdivisions must also be considered. The DCM has the authority to deny coastal development permits based on cumulative impacts. However, the research and modeling tools necessary to determine criteria for denial are lacking. *Any research and modeling effort conducted on dock impacts should address the cumulative impact of shading, turbidity, boater access, and other impacts on the quality and quantity of SAV beds.*

Fishing gear impacts

Several bottom disturbing fishing gears have the potential to destroy or damage SAV. The ASMFC SAV policy (ASMFC 1997b) urged development of technical guidelines and standards to objectively determine fishing gear impacts and develop standard mitigation strategies, in cooperation with NMFS and FWS. In North Carolina, the Fisheries Moratorium Steering Committee's Habitat Subcommittee identified specific habitat impacts from various commercial and recreational fishing gears used in North Carolina waters, and made recommendations to minimize such impacts (MFC 1996). The Fisheries Moratorium Steering Committee presented the summary of findings to the Joint Legislative Commission on Seafood and Aquaculture of the North Carolina General Assembly. Fishing gear found to be potentially damaging to SAV is listed in Table 4.7.

Table 4.7. Fishing gears used in North Carolina identified as potentially damaging to submerged aquatic vegetation habitat. *[Source: MFC 1996]*

Severe damage	Moderate damage	Low damage or unsure
Oyster dredge	Crab trawl	Long haul seine
Crab dredge	Clam Tongs	Otter trawl
Hydraulic clam dredge		Clam hand rake
Clam trawl (kicking)		Bay scallop dredge(very little)
Bull rake		

Damage from fishing gear varies in severity. Shearing or cutting of the leaves, flowers, or seeds, and uprooting of the plant without major disruption of the sediment, are most often caused by dragging or snagging of gear, such as long haul seines or bottom trawls (ASMFC 2000). Bull rakes and large oyster tongs can uproot SAV and cause substantial damage, while hand rakes are more selective and cause less damage (Thayer et al. 1984). Shearing of above ground plant biomass does not necessarily result in mortality of SAV, but productivity is reduced since energy is diverted to replace the damaged plant tissue, and the nursery and refuge functions are reduced in the absence of structure. Some fishing practices can cause severe disruption of the sediment and damage the roots of SAV. The ASMFC (2000) discussed several impacts of fishing gears on SAV. Below-ground effects, such as those from toothed dredges, heavy trawls, and boat propellers, may cause total loss of SAV in the affected area, requiring months to years to recover. SAV can be buried by excessive sedimentation associated with trawling, dredging, and propeller wash. High turbidity from use of bottom-disturbing fishing gear can reduce water clarity, affecting SAV growth, productivity, and in some cases, survival.

All toothed dredges can cause severe damage when pulled through SAV. Dredges, like trawls, are dragged across the bottom and organisms are caught in a net or cage. Oyster and crab dredges are essentially the same gears, although a few fishermen may use longer teeth to take blue crabs. Both oyster and crab dredges are limited to a weight of 45.36 kg (100 lb) in North Carolina (MFC rule 15A NCAC 03J .0303 (a)). Oyster and crab dredges have a metal frame less than 1.52 m (5 ft) wide to hold the net open and a blade at the bottom of the frame to which teeth are attached for digging the target species out of the bottom (crabs) or breaking them off from adjoining material (oysters). Qualitatively, damage to eelgrass meadows caused from unspecified dredges used to harvest shellfish was surpassed only by damage associated with propellers (Thayer et al. 1984). Because oyster and crab dredges affect bottom structure, there are strict limits on their use in North Carolina.

Use of crab dredges is restricted to an area in northern Pamlico Sound west of Oregon Inlet [MFC rule 15A NCAC 03R.0109]. In recent years, crabs have not been dredged from areas where SAV was present. However, the designated area overlaps with SAV habitat and could become a problem. Based on SAV data from the late 1980s and early 1990s (Ferguson and Wood 1994), there are 15,560 acres (6,296.91 ha) of SAV within the designated crab dredging area. Crab dredge effort is very low, with roughly 10 crab dredge trips annually in recent years. Use of oyster dredges is currently restricted to parts of Pamlico Sound and its tributaries. The majority of high salinity SAV occurs in areas where the mechanical methods for oyster harvesting are prohibited. However, brackish and freshwater SAV in western Pamlico Sound is generally unprotected from dredging, except in PNAs and SNAs.[11] However, there has been relatively little oyster dredging in the Neuse or Pamlico Rivers in recent years, indicating that most potential problems are in Pamlico Sound. Submerged aquatic vegetation will not be able to recolonize areas that historically supported SAV if they continue to be dredged. *Research is needed to determine where there is suitable potential SAV habitat along the mainland shorelines of the Albemarle-Pamlico system for the purpose of establishing defined SAV restoration goals. Once determined, oyster dredging should be prohibited from areas targeted for SAV restoration.*

Bay scallop dredges, in contrast to oyster and crab dredges, cause less severe damage to SAV because they are smaller (not over 50 lb (22.68 kg)) and have no teeth. They are intended to glide along the substrate surface, taking bay scallops lying on the surface within SAV beds. Bay scallops depend on SAV for initial post-larval setting, so they are strongly associated with SAV beds. An evaluation of impacts to eelgrass (*Zostera marina*) from bay scallop dredging in North Carolina found that scallop dredging over grass beds significantly reduced the biomass, surface area, and shoot density of eelgrass (Fonseca et al. 1984). The impacts were more severe in soft bottom compared to harder bottom. Full recovery was estimated to take up to two years. Because bay scallop populations in North Carolina typically spawn between August and December (Fay et al. 1983), eelgrass leaves are most needed for attachment of juveniles (the next season's scallop crop) during the winter, which is also the time of maximum fishing effort (Fonseca et al. 1984). However, most damage observed by DMF staff has not been from the dredge, but from propeller scarring while pulling the dredge, particularly when the season opening coincides with low tide (T. Murphey, DMF, pers. com., 2002).

The area fished with bay scallop dredges in the Albemarle-Pamlico region (Cunningham et al. 1992) encompasses approximately 46,000 acres (18,615.54 ha) of mapped SAV in eastern Pamlico, Core, Back, and Bogue sounds. Bay scallop landings have been quite variable in recent years, ranging from about 201,000 lb (91,172.07 kg) in 1995 to only 19,000 lb (8,618.26 kg) in 2002. Bay scallops are an annual crop with availability dependent on the previous year's spawning success and survival. Therefore, fishing effort is also quite variable. Reported scallop dredging trips in Core and Bogue Sound have generally declined from 1994 to 2000, peaking at around 1,800 trips in 1995 and falling to fewer than 15 trips annually by 2002 (DMF, unpub. data). Bay scallop dredges accounted for 62-92% of the harvest during

[11] The cumulative number of oyster dredge trips reported in Pamlico Sound varies annually: 224 trips (1997), 1,298 trips (1998), 239 trips (1999) and 691 trips (2000) (DMF, unpub. data).

1994-1998, but only 38% in 1999, and 3% in 2000. Most of the catch is now taken by various hand methods. The low dredge effort is due to very short periods of time open for dredging and reduced bay scallop stocks in recent years. To reduce SAV impacts, DMF allows hand harvest methods for bay scallops early in the season, followed by proclamations to open scallop dredging later in the season, starting on a high tide. This management practice is based on the presumption that the majority of the scallops have been hand harvested in the shallow beds prior to allowing dredging. By opening the first day of dredging on a rising or high tide, damage to SAV by propeller scarring from dredging vessels is minimized because the water depth is approaching or at its maximum (T. Murphey, DMF, pers. com., 2002). At that time, dredgers can harvest the few scallops hypothetically remaining in the shallow beds and then, during the course of the day, move out to the deeper water. *Research should be conducted to determine whether gear impacts or other factors are causing the decline observed in bay scallop landings that was discussed in "Status and Trends." If current bay scallop harvesting methods are found to negatively impact SAV and bay scallop populations, the DMF and MFC should consider rotation of fishing areas, as recommended in Fonseca et al. (1984), or other fishery management techniques.*

Hydraulic clam dredging can cause severe impacts to SAV. This gear directs high-pressure water jets into the bottom to blow surface sediment away and expose clams. The clams are then captured by the dredge head and brought to the surface on a conveyor belt. Hydraulic dredges dig trenches in the bottom, create mounds of discarded material, and redistribute bottom material (Adkins et al. 1983). When hydraulic clam dredging occurs in SAV beds, it digs up all vegetation in a swath approximately three feet (0.91 m) wide (ASMFC 2000). Hydraulic clam dredging can also significantly increase local turbidity (ASMFC 2000). Because of the severe impacts on the bottom, the MFC and DMF restrict use of this gear to open sand and mud bottoms, including areas frequently dredged as navigation channels such as sections of the Atlantic Intracoastal Waterway. This gear is not allowed in SAV or oyster beds and the restrictions are strictly enforced. On average, about 38 vessels make more than 600 hydraulic clam dredge trips to harvest about 72,000 lb (32,658.65 kg) of clam meats annually (DMF, unpub. data).

Another method of mechanical clamming is clam kicking. Several kicking techniques have been developed over time (e.g., anchor, bedstead, oyster drag, clam trawl); each technique uses different gear but all rely on propeller backwash to expose clams buried in the sediment to facilitate their harvest (Guthrie and Lewis 1982). The most prevalent technique currently employed in North Carolina is the clam trawl, in which a small, heavily weighted trawl is towed approximately 15 feet (4.6 meters) behind a kicking vessel (Guthrie and Lewis 1982). These vessels are modified or weighted so that the stern is low in the water, to achieve a more efficient angle and depth at which to force or deflect the propeller backwash into the bottom, thereby displacing the substrate so that the buried clams are collected in the trawl (Guthrie and Lewis 1982). Although the size of associated nets and trawl boards vary according to boat size and water depth, most kicking activities are restricted to depths below about 10 feet (3 m) (Guthrie and Lewis 1982). Some areas where this method is used (open waters of Core Sound, southeast Pamlico Sound) contain clams that otherwise might not be harvested because the areas are exposed to the wind, making it difficult for fishermen to use clam tongs. The methods and gears associated with kicking can also cause severe damage to SAV. Peterson et al. (1987) found that clam kicking reduced plant biomass in eelgrass and shoalgrass beds. Loss of SAV biomass and time needed for recovery increased as intensity of clam kicking increased (Peterson et al. 1987). The probability of historic damage to SAV via kicking seems likely to be high, given that kicking techniques were first experimented with in eastern North Carolina during the 1940s, that almost 150 kicking vessels operated in 1980 in Carteret County alone, and that kicking vessels tend to operate in shallow waters (Guthrie and Lewis 1982).

Because of the severe disturbance to the bottom, clam kicking is restricted to open sand areas in Core and Pamlico sounds, and Newport, North, New, and White Oak rivers (Maps 4.4a-b). The fishery is managed intensively, with strong enforcement to prevent clam kicking outside the designated areas. Much of the designated mechanical clamming areas have SAV in close proximity to them, so vessels that fish illegally outside the open areas may severely impact SAV. Turbidity generated by clam kicking may also affect

adjacent SAV beds. Annual effort in this fishery varies.[12] During 1994 - 2000, clam kicking accounted for about 6-12% of the annual commercial hard clam harvest in North Carolina. Mechanical clamming, including kicking and dredging, accounts for about 21% of annual hard clam landings. High salinity SAV species are more likely to be impacted by mechanical clamming practices due to the location of the fishery.

The Fisheries Moratorium Steering Committee (MFC 1996) recommended that existing areas for mechanical harvest remain, but not be expanded. However, opening a new mechanical harvest area in southeast Pamlico Sound was raised as an issue during development of DMF Hard Clam FMP. The area selected contained SAV, particularly in the shallower water. The final DMF Hard Clam FMP (2001b), added this location as a new mechanical clam harvest area, but restricted harvest to deeper waters where SAV was not present. This new area in southeast Pamlico Sound will be rotated with existing mechanical harvest areas in Core Sound to allow recovery of clam populations in each area. Turbidity and non-compliance with area restrictions could potentially damage surrounding SAV. *Turbidity impacts to SAV at this new location and other existing mechanical harvest areas should be assessed through water quality monitoring.*

Hand gears can also cause varying amounts of damage, but generally to smaller areas than mechanical gears. A hand clam rake looks similar to a garden rake, usually with nine teeth or less. Clam rakes are pulled through the sediment to obtain clams; different techniques are associated with different types of rakes, which reach different depths (Peterson et al. 1983). A bull rake is a large heavy clam rake having 18 to 24 teeth and a basket attached behind the teeth to catch the harvested clams. The length and spacing of the teeth are designed to prevent harvest of undersized clams. Clam tongs, similar to oyster tongs, are a pair of rakes attached to the end of two long poles which are fastened together like a pair of scissors. Bull rakes and large clam tongs can uproot SAV and cause substantial damage to grass beds, while hand rakes are smaller and lighter in weight, and cause less damage. (Thayer et al. 1984). A comparison of the impact of bull rakes and hand rakes on SAV found that a bull rake removed over 80% of the shoots, roots, and rhizomes in a completely raked area, while a hand rake removed 55% of shoots and 37% of roots and rhizomes (Peterson et al. 1983).

Hand clam rakes are used to take intertidal clams during all tidal stages, but are used mostly by recreational clammers during low tide (Cunningham et al. 1992). Clamming with hand rakes occurs in areas around Ocracoke Inlet in eastern Pamlico Sound and in the higher salinity sounds, rivers, and creeks from Core Sound south through Brunswick County. Bull rakes are used by commercial clam fishermen in the same general area, primarily in deeper water (such as New, White Oak, Newport, and North rivers) or during colder months. Many of the bull rake areas are in close proximity to significant SAV beds. Clam tonging occurs primarily in limited areas where there is very little known SAV. Current MFC rules prohibit use of bull rakes and clam tongs in SAV (MFC rule 15A NCAC 03K.03049 (a) (2)). Use of hand rakes and clamming by hand are allowed.

Long haul seines have been reported to cause little or no damage to SAV. A long haul seine is a long (more than 1,000 yd or 914.4 m) net that hangs in the water from the surface to the bottom. The top of the net is suspended at the surface with floats, and the bottom line ("leadline") is weighted so that it will skim the estuarine bottom. Both ends are pulled slowly through the water by boats until the end of the "haul" (Guthrie et al. 1973; DeVries 1981). The extent of damage from haul seining is dependent upon seine length, weight, and the density and height of the SAV. Possible damage includes shearing of the leaves or reproductive structures.

Long haul seine fishing is used in Croatan and Roanoke Sounds; northern and eastern portions of Pamlico

[12] Clam kicking effort: 640 trips (1994), 824 trips (1995), 1095 trips (1996), 1116 trips (1997), 1083 trips (1998), 1162 trips (1999) and 364 trips (2000) (DMF, unpub. data).

Sound along the Outer Banks; portions of the Pamlico River estuary, including the Pungo River and adjacent areas of western Pamlico Sound; and also in portions of the Neuse River estuary, West Bay, Core and Back sounds, and North River (Cunningham et al. 1992). These areas include approximately 78,148 acres (31,625.37 ha) of mapped SAV. The Fisheries Moratorium Steering Committee (MFC 1996) recommended that research be conducted to assess bottom damage associated with long haul seines. A study conducted in Chesapeake Bay found no detectable effect from this gear on plant height, density, or species composition of brackish SAV (wild celery and *Hydrilla*) in Chesapeake Bay (Sadzinski et al. 1996), indicating no need for further restrictions to protect SAV. However, use of the gear differs between North Carolina and Chesapeake Bay, with much larger nets used in North Carolina. Peak use of long haul seines occurred during the 1970s and 1980s, with far less effort in recent years (about 50–60 crews active during the peak, down to 20–25 crews by the early 1990s (DMF 1993). Trip ticket data indicate that the number of seine trips has fallen by more than half from the 1994–1996 period to the 2000–2002 period (DMF, unpub. data).

An otter trawl is another gear that may impact SAV. A trawl consists of a conical net towed behind a fishing vessel at various locations in the water column. Most types of trawls used in North Carolina are held open by water pressure against a pair of "otter boards" or "doors" attached to the front of the net. Bottom trawls used to catch shrimp, crabs, and finfish are towed along the bottom, and both the bottom weighted line ("leadline") at the opening of the net and part of the doors dig into the bottom. Many shrimp trawl fishermen attach a "tickler" chain in front of the leadline to cause shrimp to jump off the bottom in front of the net. The tickler chain also digs into the bottom to some degree.

Many studies have shown that trawling can have severe impacts to sensitive bottom habitats (Auster and Langton 1999, Collie et al. 2000). Because almost all shrimp and crab trawling occurs on sand/mud bottoms, the least complex bottom types, habitat impacts may be relatively low (Auster and Langton 1999). Where trawling does occur over SAV, impacts may occur from the dragging of the net across the seafloor and the digging of the trawl doors into the sediment (ASMFC 2000). It is estimated that the maximum cutting depth for otter trawl doors ranges between about an inch and a foot (2.54–30.48 cm) when used in depths over about 100 ft (30.48 m) (ASMFC 2000), although such deep water does not occur in North Carolina's estuaries. The variation is due to differences in gear weight, bottom hardness, and towing warp to depth ratio (a measure of the force of the gear). Trawl doors were found to penetrate the bottom more than the rest of the gear (ASMFC 2000). Crab trawling impacts to SAV are expected to be more severe than shrimp trawling because of the heavy chain used on the bottom line. However, far fewer crab trawl trips (about 2,000) occur annually than estuarine shrimp trawl trips (about 10,000).

The greatest use of trawls in North Carolina is in the shrimp fishery, with about 13,000 trips annually during 2000–2002. About 75% of the trips occur in estuarine waters, and the rest are mainly within the U.S. Territorial Sea (0-12 nautical miles or 22.22 km). Shrimp trawls are used primarily in Croatan, Roanoke, and Pamlico sounds; the Pamlico, Pungo, Bay and Neuse rivers; and in Core, Back, and Bogue sounds, including the New, White Oak, Newport, and North rivers (Cunningham et al. 1992). The areas open to trawling cover approximately 20,035 acres (8,107.88 ha) of mapped SAV. Trawling is not allowed in designated Primary or Secondary Nursery Areas (PNA, SNA) or No Trawl Areas (NTA) (Maps 3.5a-c). Low-salinity SAV beds occurring along the western shoreline of Pamlico Sound and its tributaries are protected from trawling primarily by the PNA and SNA regulations. The No Trawl Areas primarily protect high salinity SAV located along the eastern edge of Pamlico Sound, and a few areas along the western shoreline of Pamlico Sound, as well. Trawling is also prohibited in Currituck and Albemarle sounds. Core Sound and a large portion of Bogue Sound, which both contain significant amounts of SAV, are open to trawling. The average annual harvest of shrimp in Core and Bogue sounds is about 893,000 and 338,000 pounds (405,057.99 and 153,314.22 kg), respectively. The harvest indicates a substantial trawl fishery in these areas.

Fishery restrictions already exist for most of the gears used in North Carolina that are potentially

damaging to SAV. Based solely on numbers of trips and SAV acres covered, trawling in Core and Bogue sounds has the greatest potential for significant fishing gear impacts on SAV. However, without knowing the specific areas affected per fishing trip, it is difficult to evaluate the impact of these fishing gears on SAV habitat. *Field studies are needed to assess the effect of shrimp and crab trawling on SAV in North Carolina, particularly in Core and Bogue sounds. In addition, the boundaries of No Trawl Areas should be evaluated and adjusted, if necessary, to adequately protect all high salinity SAV beds and provide a buffer of unvegetated area to reduce turbidity impacts. Additional law enforcement may be needed to enforce buffers around SAV.*

In identifying potentially damaging fishing gear, the ASMFC recognized that varying physiological and habitat requirements of the different species of marine, fresh, and brackish water SAV affects their susceptibility to damage and their ability to recover (ASMFC 2000). Characteristics of concern include light requirements, location of asexual and sexual reproductive structures, dependence on sexual or asexual reproduction for maintenance and growth of beds, and ability to recover from plant damage. Species having higher light requirements (i.e., eelgrass) or whose growth and vegetative reproduction are primarily above ground or just below the sediment surface (i.e., pondweed) are more vulnerable to above-ground disturbance (ASMFC 2000). Seagrass beds composed of species that rely primarily on vegetative spreading (asexual reproduction) recover more slowly (many years) than those with species that rely more heavily on seed set and sexual reproduction (1–2 growing seasons) (Fonseca et al. 1998).

Many factors affect recovery, including the magnitude of the injury, the amount of stored energy reserves in the plant, seed or tuber set before disturbance, and local environmental conditions. Taking as many factors as possible into account, the SAV workgroup of the ASMFC estimated the relative ability of different SAV species to recover from physical impacts. The overall recovery potential of species occurring in North Carolina are listed in Table 4.8. Species having moderate potential for recovery are more sensitive to disturbance than those with high potential for recovery. No species occurring in North Carolina were listed as having a low potential for recovery.

Table 4.8. Estimated recovery potential of selected species of submerged aquatic vegetation occurring in North Carolina. *[Source: ASMFC 2000]*

Moderate Recovery Potential	High Recovery Potential
Eelgrass	Shoalgrass
Wild celery	Widgeon grass
Redhead grass	Horned pondweed
Sago pondweed	Common elodea

Water quality degradation

Nutrients and sediment

While physical damage to SAV beds generally occurs in a discrete area and within discrete time periods, water quality degradation can cause SAV loss over less defined and much larger areas and time periods. The majority of SAV loss is now considered to result from large-scale nutrient enrichment (causing enhanced epiphytic and phytoplanktonic growth) and sedimentation, which result in reductions in water transparency and light penetration (Goldsborough and Kemp 1988; Kenworthy and Haunert 1991; Funderburk et al. 1991; Stevenson et al. 1993; Dennison et al. 1993). Catastrophic losses of seagrass beds have been correlated with these water quality problems in Virginia and Florida waters (Twilley et al. 1985; Orth et al. 1986; Durako 1994). Nutrient enrichment and/or increased sediment loads impact SAV growth, survival, and productivity by:

- Increasing chronic turbidity in the water column from suspended sediment or phytoplankton associated with algal blooms,

- Increasing epiphytic loads, sedimentation, or covering by drift algae on the SAV blades, and
- Diminishing dissolved oxygen concentrations as photosynthesis decreases, coupled with increasing concentrations of hydrogen sulfide resulting in toxicity (Dennison et al. 1993; SAFMC 1998; Fonseca et al. 1998).

The effects of human-related eutrophication on seagrass survival are dependent on the growth periods and environmental requirements of the dominant species, and the timing and duration of the water quality problem (Burkholder et al. 1994). Eutrophication effects are generally most severe in sheltered habitats with reduced tidal flushing where nutrient loadings are concentrated and frequent, and where temperature fluctuations may be greater (Burkholder et al. 1994). Therefore, optimal criteria for preventing eutrophication vary by salinity, species, time of year, and specific location of SAV beds.

Decreased water clarity due to dissolved organic matter, suspended particulate matter, detritus, or algae that is suspended in the water column has a major effect on SAV distribution[13]. In addition to light attenuation in the water column, sedimentation and algal growth on the surface of grass blades (epiphytes) also reduce light reaching the surface of SAV (Virnstein and Morris 1996). Because algal growth is directly related to dissolved nutrient concentrations, epiphyte loads are considered to be caused by excessive nutrients in the water column.

Loss of SAV habitat, whether from physical impacts or water quality degradation, leads to a "snowball effect" of additional habitat and water quality degradation (Durako 1994; Fonseca et al. 1998). In the absence of SAV, the ability of the rooted grasses to bind sediment and baffle wave action is reduced, which results in sediment destabilization and increased turbidity. The destabilized bottom can result in accelerated shoreline erosion, putting more sediment into the water, decreasing water clarity further. These effects, in turn, can lead to additional SAV loss above and beyond the initial impact area or reduce the rate of recolonization (Durako 1994; Fonseca 1996). Large-scale losses of SAV are particularly problematic because the rate of recovery (measured in the scale of years) often cannot keep up with the rapid rate of losses (occurring within weeks or months) (Fonseca et al. 1998). Furthermore, future seagrass restoration may be confounded by the loss of existing seagrass beds, which increases sediment resuspension and turbidity (P. Biber, NMFS, pers. com., 2003). *Therefore, management efforts should focus on protecting existing SAV habitat and preventing any additional direct or indirect losses.*

Several water quality variables can be used as indicators of light conditions, including turbidity, total suspended solids, chlorophyll levels, and color (EPA 2000). Turbidity is a measure of the reduced transparency of water due to suspended or dissolved substances, while total suspended solids is a measure of the density of suspended solids in the water column. Chlorophyll *a* is a measure of the abundance and variety of phytoplankton in the water column. Chlorophyll levels may have the greatest impact on SAV in spring and summer (EPA 2000). Color is an indication of the amount of dissolved organic matter in the water.

In North Carolina, there is no official standard for light attenuation or light availability. There are EMC standards for other light associated parameters including turbidity, total suspended solids, and chlorophyll *a*. The standards for water clarity parameters are listed in Table 4.9 for the different water quality classifications. Waters classified as Nutrient Sensitive Waters (NSW) in the CHPPs area include the Neuse, Tar-Pamlico, and Chowan river basins, and the New River watershed within the White Oak river basin. In general, no increase in background nutrient levels is allowed within NSW waters unless preventing the increase would result in serious economic hardship, would not endanger human health and safety, or is due to natural variations. In both the Tar-Pamlico and Neuse basins, nitrogen limits were placed on point source discharges, and BMPs were established with the goal of reducing annual nitrogen loading by 30% of the amount occurring during a selected past year (DWQ 2000b). In the Chowan River

[13] see Habitat requirements section.

basin, the updated 1990 NSW strategies called for reducing nitrogen inputs from all sources by 20%, as well as targeting BMP implementation. In the New River, nitrogen limits were placed on point source discharges, no new discharges were permitted, and expansions of existing facilities were allowed only if there was no increase in permitted loading of oxygen-consuming waste.

High Quality Waters include all waters designated SA for harvesting of shellfish, as well as, Primary Nursery Areas designated by the MFC. Standards for those waters are shown in Table 4.8. For Outstanding Resource Waters, standards are based on the primary classification of those waters or if the standards are found to be insufficient to protect the ORW resource(s), then site-specific standards may be developed as part of the management strategy and rule-making process.

In the Chesapeake Bay, a multi-state and federal effort is underway to restore Chesapeake Bay water quality and SAV, in part by defining specific water quality criteria for water clarity, chlorophyll *a*, and dissolved oxygen as part of the process of maintaining and restoring SAV and other habitat. These parameters were considered the best and most direct measure of the effects of excessive nutrient and sediment pollution on SAV and other resources (<http://www.chesapeakebay.net/>, 2002).

In comparing current North Carolina water quality standards to those proposed for the Chesapeake Bay, North Carolina's chlorophyll *a* standard is higher (40 µg/l vs. <15 µg/l), while the TSS standard is very similar (10-20 mg/l vs. <15 mg/l) (Tables 4.2 and 4.9). The EPA did not list a standard for turbidity for the Chesapeake Bay (EPA 2000). Historically, water clarity standards have been based on phytoplankton requirements, which are much lower than that required for submerged grasses–only approximately one percent of incident light, compared to 15–25% (Kenworthy and Haunert 1991). Research is currently being conducted at NMFS in Beaufort to determine specific light requirements for SAV in North Carolina's estuaries and the relationship between light attenuation and other water quality parameters (P. Biber, NMFS, pers. com., 2004). Preliminary results indicate that, given certain combinations of turbidity and nutrients, North Carolina's current standards may not be adequate to sustain SAV (P. Biber, NMFS, pers. com., 2004). *Modifications may be needed to regulations and monitoring programs to improve their effectiveness for SAV protection. A review of current chlorophyll, TSS, and turbidity standards should be conducted to determine if they are appropriate for the protection of SAV in North Carolina waters. DENR should work with NMFS to determine what levels of TSS, chlorophyll a and other parameters are needed to achieve desired water clarity. The need and feasibility (scientific defensibility and "implementability") for a water quality standard for light attenuation should be investigated to provide a pro-active target or standard for protection and restoration of SAV.*

Minimal water quality monitoring is conducted in Pamlico and Core Sounds by DWQ, where the vast majority of SAV coverage occurs. The North Carolina light-associated water quality standards adopted by the EMC that apply directly to SAV are shown in Table 4.9. *Once the appropriate water quality conditions for protection of SAV are determined, DWQ should evaluate whether current sampling locations and methods are sufficient in estuarine waters to monitor the suitability of water quality conditions for SAV survival and growth. Monitoring should be conducted in waters with SAV habitat to ensure that the standards and conditions are being met. If additional monitoring is needed, establishment of continuous monitoring stations should be considered. In either case, priority should be given to those areas already classified NSW.*

Table 4.9. North Carolina Environmental Management Commission standards for light-associated parameters by North Carolina surface water quality classifications.

Parameter	Supplemental Classifications			Salt water			Fresh water
	ORW	HQW (salt or fresh)	NSW	SA	SB	SC	Aquatic life
Turbidity (NTU)	**	25	**	25	25	25	50

Chlorophyll *a*	**	40	**	40	40	40	40

* Applies to discharges only

** Determined by primary classifications (SA – SC and C) or site-specific management strategies developed by EMC through rule-making.

In North Carolina, between 1995 and 1999, chlorophyll *a* concentrations at or above the state surface water quality standard of 40 µg/L were identified as one of the major causes of impairment in the freshwater portions of the Neuse and White Oak River basins (Table 4.10) and in the saltwater portions of the Neuse, Tar-Pamlico, and White Oak River basins. During calendar year 2000, 183 algal bloom samples were received from the basins included in the CHPPs area [14]. The Neuse (Maps 4.3a-b), Tar-Pamlico, and White Oak river basins support SAV habitat, and at one time supported larger grass bed areas. Since some SAV is present in the shallow portions of the Neuse and portions of the White Oak river basins, and water quality data indicate some level of eutrophication exists, nutrient levels may be limiting survival or expansion of SAV in these areas. *These areas should be a high priority for monitoring of SAV and water clarity.*

Research has shown that elevated nitrogen concentrations not only affect SAV through light reduction, but may actually be toxic to eelgrass. In laboratory experiments, long-term exposure of eelgrass to enriched nitrate concentrations was lethal at enrichment levels ranging from 3.5 – 35 µM water column NO_3^- - Nd^{-1} (Burkholder et al. 1992). In another experiment with eelgrass, nitrogen enrichment (10 µM water column NO_3^- - Nd^{-1} for 14 wk) significantly lowered shoot production compared to control plants without nitrogen enrichment (<2 µM water column NO_3^- - Nd^{-1}) (Burkholder et al. 1994). In contrast, growth in shoalgrass and widgeon grass was stimulated by similar nutrient enrichment conditions (Burkholder et al. 1994). Widgeon grass shoot production actually increased by 300%. These results indicate that of the three species studied, eelgrass would be most impacted by eutrophication. The results also suggest that shoalgrass or widgeon grass might be successfully established by transplanting efforts in areas where eelgrass beds have been lost (Burkholder et al. 1994). More research is needed on the effect of nutrient enrichment on other brackish and freshwater species of SAV.

[14] 50 samples from the Tar-Pamlico River Basin, 79 from the Neuse River Basin.

[1] Habitat degradation is identified where there is a notable reduction in habitat diversity or change in habitat quality. This term includes sedimentation, bank erosion, channelization, scour, loss of pools or riffles, and loss of woody habitat.

Over the past several decades, there have been some nutrient reductions in waters supporting SAV due to improvements in wastewater treatment systems (Glasgow and Burkholder 2000), the 1988 ban on phosphorus-detergents (<http:www.water.usgs.gov/pubs/circ/circ1157/nawqa91.5.html>, June 2002) and more stringent water quality and management strategies in NSW areas (DWQ 1997). Despite efforts to reduce nutrient loading, nutrient concentrations will continue to fluctuate as bottom sediments containing nutrients are resuspended into the water column and stormwater runoff introduces additional nutrients, varying with rainfall and runoff patterns. In addition, increasing population along the coast potentially increases nutrient loading into wastewater systems and nonpoint runoff. Nutrient and sediment levels may be preventing recovery of SAV in areas that historically supported SAV. The edges of existing SAV beds mark the general transitional area where water quality conditions become adequate to support SAV (Virnstein and Morris 1996). *To restore SAV habitat in fresh and estuarine systems where it historically occurred, management strategies should focus on water quality improvements at the edges and upstream of SAV occurrence.*

Suspended sediment, suspended solids, and dissolved solids concentrations have decreased throughout the Albemarle-Pamlico watershed from 1980 to 1995 (<http://water.usgs.gov/pubs/circ/circ1157 /nawqa91.9.html>, June 2002). Decreasing concentrations of suspended solids in the sounds and estuaries may not adequately improve water clarity for SAV growth if nutrient levels remain high. As a

result, reduction of nutrients will be even more important in controlling water clarity conditions for SAV.

Increased sediment and nutrient loading in the water column can enter coastal waters from point source discharges, nonpoint stormwater runoff, or resuspension of bottom sediments. Specific sources that contribute to increased sediment loading include construction activities, unpaved roads, road construction, golf courses, uncontrolled urban runoff, mining, silviculture, row crop agriculture, and livestock operations (DWQ 2000b). Urbanization can increase the flow and velocity of stormwater runoff, which in turn leads to increased stream bank erosion. Stream bank erosion is a significant source of sediment loading (DWQ 2000b). Specific sources that contribute to increased nutrient loading include agricultural and urban runoff, wastewater treatment plants, forestry activities, and atmospheric deposition. Nutrients in point source discharges are from human waste, food residues, cleaning agents, and industrial processes. The primary contributors of nutrients from nonpoint sources are fertilizer and animal wastes (DWQ 2000b).

Addressing wetland and riparian restoration and management can reduce the effects of nonpoint pollution on water quality. Reductions in sediment or nutrient loading, particularly in river basins draining to the northern two-thirds of the coast (Albemarle Sound south through Topsail Sound), would help maintain or improve water clarity and light conditions needed for SAV growth and survival. *Nonpoint source loading of nutrients and sediment could be reduced through multiple strategies, including preservation and restoration of upland and wetland riparian habitats, modifications in land use regulations, agricultural BMPs, and forestry management activities. Conservation priorities should be set for land acquisition programs which will aid in protecting Strategic Habitat Areas.*[15] *Nutrient and sediment reduction goals should be established by the EMC to achieve the minimum of 15-25% light availability at depth requirement for SAV growth. An increase in staffing to fully implement and enforce existing stormwater and other nonpoint source-related regulations is needed to achieve this goal.*

Implementation of NSW rules for the Neuse, Tar-Pamlico, Chowan, and New rivers by the EMC are positive steps needed for nutrient and sediment reductions from both point and nonpoint sources. Goals and strategies vary, but in general aim to obtain nutrient reductions ranging from 20 to 40 % of a targeted previous year, depending on the river basin. In addition, implementation of the CRC's coastwide 30 ft (9.14 m) buffer rule [CRC rule 15A NCAC 07H .0209 (d)(10)], and EMC's 50 ft (15.24 m) buffer [16] in the Neuse and Tar-Pamlico river basins [EMC rule 15A NCAC 02B.0232 and 2B.0229] should aid in reducing nonpoint pollution. *The New River nutrient management strategy (EMC rule 15A NCAC 02B.0223) was heavily focused on point sources and should be revisited to determine what additional controls, such as buffers, might be necessary to achieve continued water quality improvements.*

The presence of SAV can, in itself, be valuable as a sensitive indicator of water quality (Smith et al. 1981; Valiela et al. 1990). In the Indian River Lagoon, Florida, where stormwater runoff has caused large SAV losses, SAV is used as a barometer of overall water quality conditions because of its sensitivity to water quality, the ecological value and functions it provides, and its importance as a keystone species for numerous other species (Virnstein and Morris 1996). To manage the Lagoon, light attenuation models have been developed that link water quality to seagrass health. From the information obtained, pollution load reduction goals were developed to maintain and extend SAV coverage to historically occurring depths. Seagrass acreage and density were used as the measures of success. The conceptual model was based on the following relationship, which is supported in the scientific literature (Virnstein et al. 1983; Thayer et al. 1984; Gilmore 1995):

[15] Because nonpoint source pollution also affects other habitats as well, including oyster reefs, soft bottom, tidal marsh, and the water column, this topic is discussed in more detail in the Water Column habitat section of this plan.

[16] First 30 ft (9.14 m) from water must remain forested and undisturbed and the next 20 ft (6.10 m) must have at least grass vegetation.

Proper watershed management → Adequate water quality → Healthy SAV coverage → High biological productivity and diversity → Healthy fish populations

The SAMFC SAV policy (1998) encourages long-term trend analyses to monitor distribution and abundance of SAV. An approach similar to that used in Indian River Lagoon and the Chesapeake Bay, where the condition of water quality, SAV, and fish populations are linked in monitoring and management, would be useful for protection of SAV habitat in North Carolina.

Toxic chemicals

Herbicides are the primary toxic chemical known to have negative impacts to SAV (Funderburk et al. 1991). Herbicides enter riverine and estuarine waters from agricultural runoff and other sources. The most common agricultural herbicides used in Chesapeake Bay were atrizine, simazine, diquat, paraquat, and linuron. Research in Chesapeake Bay found that concentrations of the toxins in the water column were seldom high enough to damage SAV beds. In addition, SAV recovery was rapid following exposure to low concentrations of herbicides (Funderburk et al. 1991). However, impacts to SAV from sporadic or localized pulses of higher concentrations are not known, and could potentially cause problems.

While most agricultural herbicides come in contact with SAV indirectly through runoff, there are other chemicals specifically developed for aquatic weed control in freshwater and brackish systems. These chemicals are designed to be short-lived and should not persist in the water for long periods of time. Aquatic herbicides are at times used to intentionally kill SAV that is considered a nuisance. The Division of Water Resources, under the Aquatic Weed Control Act of 1991, manages the North Carolina Aquatic Weed Control Program, under direction from the Aquatic Weed Control Council. This program primarily focuses on non-native invasive species in freshwater lakes, ponds, and rivers. Some of the annual control activities occur in fresh and low salinity waters used by anadromous fishes and blue crabs, including the Albemarle Sound system.

The non-native European watermilfoil is the most troublesome SAV species in low salinity waters. It sometimes forms dense beds that can interfere with boating in local areas. Native submerged grasses may be impacted indirectly where occurring near treated areas or directly when herbicides are used by the general public. There is a general perception by some of the public that SAV is a nuisance. Grass blades may get in boat propellers, or entangle or weigh down fishing gear. Aesthetically, swimmers may prefer a sand bottom to a grass bottom. *Permitting for chemical removal of European watermilfoil and other non-native vegetation should be carefully restricted where native species co-occur to prevent non-target impacts. More education on the value of SAV to the health of North Carolina's estuaries and fisheries is needed to modify attitudes toward this habitat and improve individual and community stewardship of SAV.*

Introduced and nuisance species

The North Carolina Aquatic Weed Control Program is mandated by the North Carolina Aquatic Weed Control Act of 1991 [General Statute 113A-220 *ff; DENR rules 15A NCAC 02G .0600*] to assist local governments with aquatic weed problems affecting public waters. (<http://www.ncwater.org/Education_and_Technical_Assistance/Aquatic_Weed_Control/>, May 2002). Primary species targeted for control under the Act include:

- Giant salvinia (*Salvinia molesta*)
- Hydrilla (*Hydrilla verticellata*)
- Alligator weed (*Alternantherea philoxeroides*)
- Parrot feather (*Myriophyllum aquaticum*)
- Eurasian watermilfoil (*Myriophyllum spicatum*)

These highly invasive non-native species form dense beds in the water, which can make swimming, fishing, and boating difficult; clog water intake systems for municipalities and industries; and impede water flow in drainage canals (<http://www.ncwater.org/Education_and_Technical_Assistance/Aquatic_Weed_Control/>, May 2002). Because of the dense mass of vegetation, beds of Eurasian watermilfoil can cause the water column to go anoxic at night, which can stress fish or cause fish to leave the area (T. West, ECU, pers. com., 2003). Of the targeted species, parrot feather and Eurasian watermilfoil are submerged rooted grasses. These nuisance species do provide some beneficial fish functions, such as refuge and sediment stabilization. They can also negatively impact SAV habitat by shading or out-competing other native species, which may have greater value to fish as a food source or refuge area (DWR 2002). *Long-term management and restoration of SAV habitat should include replacement of Eurasian watermilfoil with native species. The DENR should coordinate with the Division of Water Resources to ensure that native species are not targeted for removal. Research is also needed to determine the relative fishery value of Eurasian watermilfoil compared to native vegetation.*

While most introductions of non-native fish have little noticeable effect on habitat, grass carp can have a significant of submerged grass beds. Grass carp is a non-native species that has escaped from stocked ponds and reservoirs into some river systems. North Carolina requires that only sterile triploid grass carp be used for stocking because of their potential damage to submerged vegetation. However, a recent study in the Chesapeake Bay found that although stocking of sterile grass carp has been required for over 20 years, 18% of the non-native grass carp were not sterile (Schultz et al. 2001). Non-native species may also be introduced through unintentional releases from aquaculture and live bait facilities. *Policies should be developed by state agencies overseeing aquaculture and bait facilities to prevent such releases into coastal waters.*

Other threats

Seagrass wasting disease is a natural event that has affected SAV in North Carolina and may occur when SAV is stressed. Historic population losses of large vertebrate grazers may have, among other consequences, increased seagrass vulnerability to infection by pathogens (Jackson et al. 2001). It was suspected, but never proven, that the slime mold protist, *Labryinthula*, was the cause of the wasting disease event that devastated eelgrass populations throughout the North Atlantic between 1930 and 1933, dramatically disrupting estuarine systems (Steel 1991). Higher water temperatures apparently stressed the seagrasses, making them more susceptible to *Labryinthula*. Healthy eelgrass beds were generally reestablished by the 1960s. More recently, similar large-scale die-offs of eelgrass from Nova Scotia to Connecticut, and turtle grass in Florida Bay have been attributed to *Labryinthula* (Short et al. 1987). Eelgrass infected with *Labryinthula* was also found near Beaufort, North Carolina in the 1980s (Short et al. 1987). Recent studies indicate that characteristics of wasting disease are appearing in some eelgrass beds in southern Core Sound, Back Sound and Bogue Sound (SAFMC 1998). Submerged aquatic vegetation is less susceptible to infection by the pathogen in low salinity waters (Short et al. 1987). Potential impacts in North Carolina include reductions in bay scallops and other fisheries resources, and large reductions in migratory waterfowl populations. Although the current infections have not caused catastrophic declines in eelgrass populations such as occurred in the 1930s, the disease is a potential threat to coastal fisheries should large-scale mortalities occur. *Submerged grasses need to be monitored on a regular basis to assess the status of wasting disease and its association with human-induced stresses.*

Existing management measures

Regulatory designations of coastal waters can either protect or potentially allow degradation of SAV habitat. The MFC-designated crab spawning sanctuaries, mechanical oyster harvest prohibited areas, military restricted areas, fish nursery areas, and trawl net prohibited areas protect SAV in those areas from potential physical disturbance associated with bottom fishing gear (Maps 3.5a-c). The great majority of SAV beds along the eastern perimeter of the Albemarle-Pamlico system are protected within these areas. However, SAV occurring in the western portion of the Albemarle-Pamlico system is generally not within

these gear-restricted areas. Moreover, the likelihood of sedimentation and eutrophication are relatively greater on the sounds' western perimeter due to the closer proximity of river discharge. Although SAV functions as a nursery for many economically important species, SAV is predominantly absent from designated fish nursery areas. In particular, most of the high salinity SAV beds are not designated Primary Nursery Areas. The *DMF should develop criteria for designating Strategic Habitat Areas and designate SAV areas that meet those criteria.*

The largest spatial gap in SAV protection from fishing gear impacts is in northern Pamlico Sound where dredging for crabs is allowed. This area includes SAV beds in the Sound immediately west of Pea Island National Wildlife Refuge. There are smaller areas of unprotected SAV along both the eastern and western sides of Roanoke Sound and along the shoreline of West Bay in the southern Pamlico Sound area. The extensive SAV beds of Core and Bogue sounds are protected from mechanical oyster methods, but not from trawling or from bay scallop dredging. Area designations that could result in SAV impacts include mechanical clam harvest areas and areas where trawling and bay scallop dredging occur. Most of the designated mechanical clam harvest areas are not located where SAV is found (Maps 4.4a-b). Areas open to trawling generally do not support SAV, since SAV is limited in occurrence to shallow water. However, SAV does occur in Core and Bogue sounds where trawling and bay scallop dredging are allowed. *The DMF should assess the effect of trawling and dredging activities in Core and Bogue sounds on SAV. The DMF should also assess where additional protective distances are needed between SAV and bottom disturbing fishing methods, including clam trawling (kicking), oyster dredging, crab dredging, bay scallop dredging, and bottom trawling.*

There are several regulations and designations that provide some direct and indirect protection of SAV beds. Area designations that provide water quality protection for SAV include Primary Nursery Areas (PNAs), High Quality Waters (HQWs), and Outstanding Resource Waters (ORWs). The CRC prohibits new dredge and fill activities in areas with SAV, but maintenance dredging of existing permitted navigation channels is allowed. Rules of the CRC do not allow authorization of projects that can violate water quality standards of estuarine resources, including SAV and PNAs [CRC rule 15A NCAC 07H .0207]. CRC rules state that activities directly impacting SAV, such as dredging or construction of docking facilities, should be avoided (CRC rule 15A NCAC 07H .0209(d)(4). Waters designated as PNAs by the MFC, or that have a special water quality classification by the EMC, such as ORW, are given additional consideration for impacts by DCM prior to issuing development permits. Despite these additional considerations, permits that result in cumulative impacts to SAV, particularly from dock construction, continue to be authorized, (T. Murphey, DMF, pers. com., 2002).

Several Outstanding Resource Waters (classified by the EMC) have significant SAV coverage. The ORW designation carries with it more site-specific management strategies based on the resources to be protected, as well as some minimum requirements for discharges and development. For example, new development adjacent to ORW waters must comply with specified stormwater provisions [EMC rule 15A NCAC 2H .1007] and non-discharge permits are required to meet reduced loading rates and increased buffer zones. Outstanding Resource Waters and their more stringent water quality standards, as adopted by the EMC, cover approximately 25% of the mapped SAV habitat in coastal North Carolina. Submerged aquatic vegetation habitat within ORWs is located in Core Sound, western Bogue Sound, and the lower White Oak River (Maps 2.4a-b). *The remaining 75% of mapped SAV should be evaluated for designation as Outstanding Resource Waters or Strategic Habitat Areas to invoke adequate protective measures.*

Because development and associated impacts occur in areas adjacent to existing ORWs, such as in the Bogue Sound area, the designation of waters alone will not effectively protect habitats unless the rules associated with those designations are adequate and enforced. *The effectiveness of ORW and HQW rules in protecting SAV and other habitats should be examined and strengthened as necessary. The EMC, CRC, and MFC should develop appropriate management strategies that maintain water quality at a level that adequately protects SAV.*

In 2003 the MFC adopted a policy statement for protection of SAV habitat. The document summarizes the habitat value of SAV and provides management guidelines for protection of SAV, to aid in development of habitat protection and fishery management plans. These management needs are listed below.

- *In order to delineate and assess the distribution and health of SAV habitat, SAV beds need to be mapped and monitored. The saltwater end of coastal waters supports eelgrass, widgeon grass and shoalgrass, and the freshwater end supports several species of freshwater SAV.*
- *Minimize nutrient and sediment loading to coastal waters that support existing SAV to protect adequate water quality as defined by water-column clarity in standard measurement units.*
- *All SAV needs to be protected from all bottom-disturbing fishing and recreational gear. Sufficient buffer zones surrounding SAV beds should also be protected from disturbance to prevent impacts of sediments on growing SAV.*
- *Provide adequate safeguards to prevent direct (or indirect) impacts from development projects adjacent to or connected to SAV.*
- *Assess cumulative impacts of land use and development changes in the watershed affecting SAV to identify the potential impact. Require identification of cumulative impacts as a condition of development of permit applications.*
- *Require compensatory mitigation where impacts are unavoidable. Initiate restoration programs to recoup an/or enhance lost SAV habitat.*
- *Educate landowners adjacent to SAV, boaters, and other potential interested parties about the value of SAV as a habitat for many coastal fishes and invertebrates.*

Commission actions (MFC, CRC, and EMC) should be consistent with this policy.

4.5 SUMMARY OF SUBMERGED AQUATIC VEGETATION CHAPTER

Submerged aquatic vegetation is an extremely valuable fish habitat that occurs in North Carolina's coastal estuarine and freshwater systems. Because light is the primary limiting factor affecting its distribution, SAV is restricted to relatively shallow waters. Submerged aquatic vegetation provides ecosystem functions similar to shell bottom, such as enhancing water quality through stabilizing and trapping sediment, reducing wave energy, cycling nutrients within the system, and providing structure for invertebrate attachment and refuge from predators. Seagrasses also produce large quantities of organic matter, which supports a complex food base for coastal fishes and other organisms. This habitat is especially valuable as a nursery and refuge from larger predators for the young of many important commercial and recreational fishery species. Bay scallops, pink shrimp, hard clams, gag, black sea bass, summer flounder, and others are typically associated with high salinity SAV. Juvenile striped bass, striped mullet, brown and white shrimp, Atlantic croaker, and others frequently use low salinity grasses. Red drum and blue crabs are among several species that rely upon both low and high salinity grasses at different stages of their life cycles. The high fisheries value of this habitat has been well established by the scientific community, and SAV is federally designated as a Habitat Area of Particular Concern for penaeid shrimp, blue crab, and red drum.

Historical accounts indicate that there have been large-scale losses of SAV in North Carolina's low salinity tributaries on the mainland side of Pamlico Sound and along much of the shoreline of western Albemarle Sound, while the high salinity grass beds to the east appear relatively stable. Loss of low salinity SAV habitat could be particularly detrimental to the southern/central stock of striped bass, which is currently classified as Overfished by DMF in 2003, as well as stocks of striped mullet, Atlantic croaker, and blue crab, which were listed as Concern. Impacts to high salinity SAV beds could be especially detrimental to bay scallops and black sea bass (south of Hatteras), which are currently listed as Overfished. Protection, enhancement, and restoration of this habitat are high priorities for recovery of those species and for sustained health of many others.

The major threat to SAV is large-scale nutrient enrichment and sediment loading, which increases turbidity, reduces light penetration, and subsequently impacts SAV growth, survival, and productivity. In North Carolina, most of the low salinity areas that have experienced large reductions in SAV coverage are also designated Nutrient Sensitive Waters. Major contributors of nutrients and sediments include point source discharges, nonpoint runoff (from crop agriculture, animal operations, urban and road construction, and impervious surfaces) and resuspended sediments (from bottom disturbing fishing gear and channel dredging). There are also activities that threaten the physical structure of SAV. Dredging for navigational channels, marinas, or infrastructure such as bridges or cables can result in large, direct losses of SAV. Docks constructed over SAV can cause immediate loss during construction or gradual loss due to shading effects. Boating activity in shallow vegetated waters can damage SAV from propeller damage to SAV. Bottom disturbing fishing gears used within or near SAV habitat, such as oyster and crab dredges, hydraulic clam dredges, clam trawls, and bull rakes, may cause significant damage to SAV habitat. As human population, boating activity, fishing pressure, and shoreline development increase, losses of SAV are likely to continue if steps are not actively taken to protect SAV and maintain suitable water quality conditions. State and local managers need to ensure that 1) SAV habitat is not physically impacted by water-dependent activities and 2) water quality (especially clarity) is enhanced to allow persistence of existing SAV and re-colonization of former habitat.

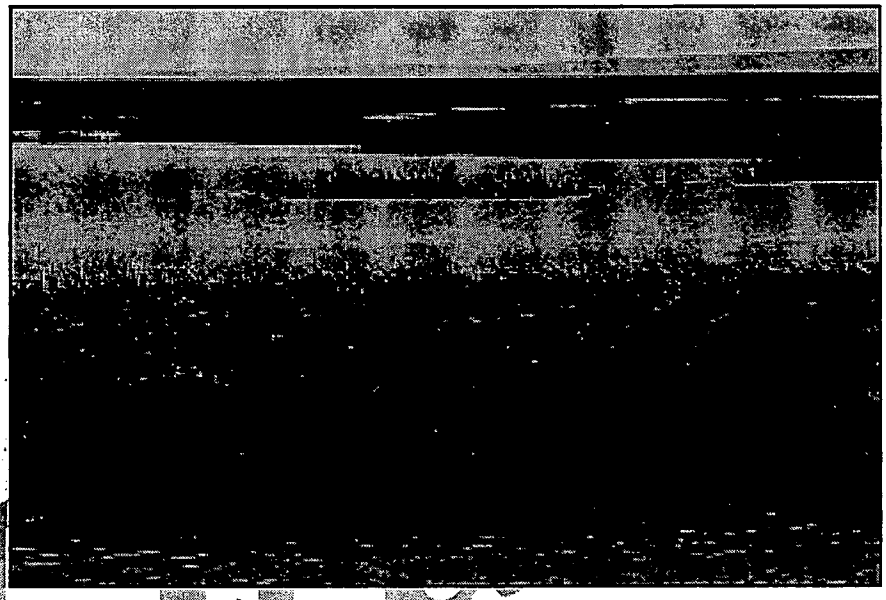
CHAPTER 5. WETLANDS

Wetlands are widely recognized as habitats vital to fisheries production in North Carolina and elsewhere (Mitsch and Gosselink 1993; Graff and Middleton 2003). This chapter defines and describes wetland habitats found in coastal North Carolina and documents their current distribution, ecological role, biological function, current status, trends, threats, and management needs.

Coastal wetlands border vital nursery areas and serve as the primary buffer between land and water-based impacts.



5.1. DESCRIPTION AND DISTRIBUTION

Definition

Wetlands are wet areas commonly referred to as swamps, marshes, bogs, or similar terminology. Wetlands, as defined by federal regulations [40 CFR 230.3(t)] and EMC rules [15A NCAC 2B .0202(71)], are "...areas that are inundated or saturated by an accumulation of surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions." The boundary between wetlands and deepwater habitat (i.e., submerged aquatic vegetation) is defined as the maximum depth where rooted emergent vegetation (i.e., marsh grasses) can be found - generally <6ft (2m) below mean low water during the growing season (Figure 5.1). The EMC and federal regulatory definitions include nontidal freshwater wetlands not subject to CRC rules. The CRC refers to coastal wetlands as "marshlands," defined as "any salt marsh or other marsh subject to regular or occasional flooding by tides, including wind tides (whether or not the tide waters reach the marshland areas through natural or artificial watercourses), provided this shall not include hurricane or tropical storm tides" [G.S. 113-229(n)(3)]. The CHPP will focus primarily on wetlands that are connected to coastal water bodies by surface water of sufficient depth to allow fish utilization. These "connected" wetlands are hereby termed "riparian wetlands" because they border streams and other water bodies.

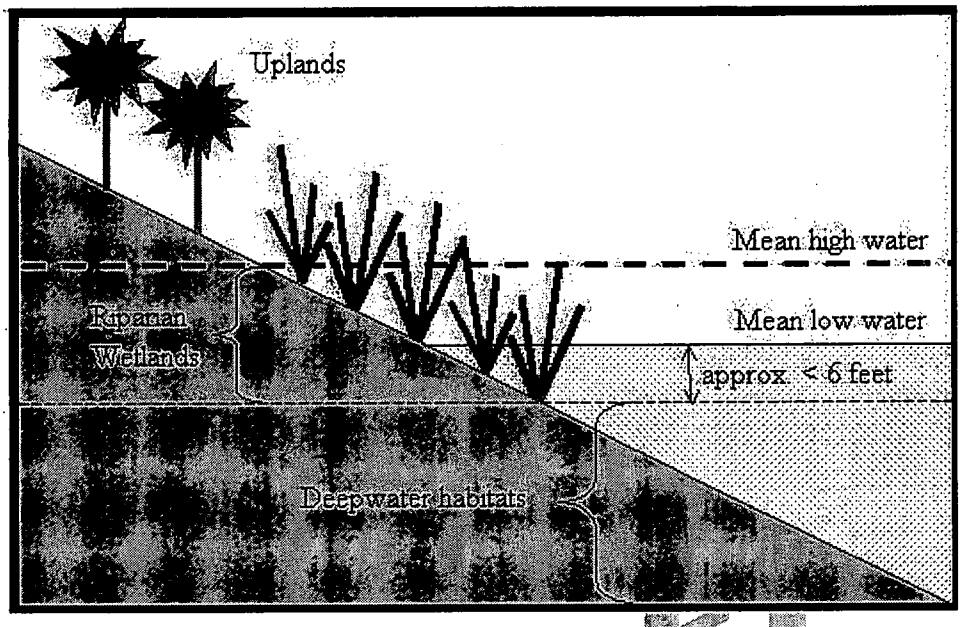


Figure 5.1. Graphic depiction of the conceptual boundaries among riparian wetlands, uplands, and deepwater habitats.

Description

Riparian wetlands can be differentiated into four broad wetland classes based on their landscape position within drainage networks (hydrogeomorphology): estuarine, riverine, headwater, and flat/depressional (Sutter 1999).

- **Estuarine wetlands** are generally found along the margins of estuaries and sounds. Estuarine wetlands include salt/brackish marsh, estuarine shrub scrub and estuarine forests.
- **Riverine wetlands** are those in which hydrology is determined or heavily influenced by proximity to a perennial stream of any size. Overbank flow from the stream exerts considerable influence on the hydrology of larger streams. Riverine wetlands include freshwater marshes, bottomland hardwood forest, and riverine swamp forest.
- **Headwater wetlands** exist in the uppermost reaches of local watersheds upstream of perennial streams. Headwater systems may contain channels with intermittent flow, but the primary sources of water input are precipitation, overland runoff, and groundwater discharge rather than overbank flow from a stream.
- **Flat/depressional wetlands** are generally not in direct proximity to surface water. While they are isolated from or hydrologically disconnected from surface water, the hydrology of depressional wetlands is primarily determined by groundwater discharge, overland runoff, and precipitation. Flat/depressional wetlands include pocosins, pine flats, depressional swamp forest, hardwood flats, maritime swamp forests, and some managed pinelands. They are also referred to as non-riparian wetlands.

While fish occupy riverine and estuarine wetlands (Map 5.1a-d) during periods of regular inundation, headwater and flat/depressional wetlands (Map 5.2) are generally not directly utilized by fish. However, there are some exceptions. The pocosins adjacent to the Alligator and Northeast Cape Fear rivers have surface drainage to coastal waters (Brinson 1991). However, the primary focus of this chapter is the riparian wetlands found in estuarine, riverine, and headwater systems.

Estuarine wetlands

- **Salt/brackish marsh** is defined by DCM using the CAMA definition for coastal wetlands. Salt/brackish marsh is therefore defined by the plant species it contains: smooth cordgrass, black needlerush, glasswort, salt grass, sea lavender, bulrush, saw grass, cattail, salt-meadow grass, and salt reed-grass [G.S. 113-229(n)(3)].
- **Estuarine forested wetlands** are subject to occasional flooding by tides, including wind tides (whether or not the tide waters reach the marshland areas through natural or artificial watercourses). Examples include pine-dominated communities with rushes in the understory or fringe swamp communities, such as those that occur along large back barrier estuaries like Albemarle and Pamlico sounds. Estuarine forested wetlands are common in upper estuarine sections of coastal rivers.
- **Estuarine shrub/scrub** is any shrub/scrub dominated community subject to occasional flooding by tides, including wind tides (whether or not the tide waters reach the marshland areas through natural or artificial watercourses). Typical species include wax myrtle and eastern red cedar. Examples include areas along the sound shorelines of barrier islands.

Riverine wetlands

- **Freshwater marshes** are defined by DCM as herbaceous areas that are flooded for extended periods during the growing season. Included are marshes within lake systems, managed impoundments, some Carolina Bays, and other non-tidal marshes (i.e., marshes which do not fall into the salt/brackish marsh category). Typical communities include species of sedges, millets, rushes and grasses that are not specified in the coastal wetlands regulations. Also included are giant cane, arrowhead, pickerelweed, arrow arum, and smartweed. Such marshes occur in the coastal waters of the Trent River near New Bern and along parts of the Cape Fear and Northeast Cape Fear rivers.
- **Bottomland hardwood forests** and **riverine swamp forests** are generally forested, or occasionally scrub/shrub, communities usually occurring in floodplains, that are semi-permanently to seasonally flooded. Bottomland hardwood forests contain mostly oaks (overcup, water, laurel, swamp, chestnut), sweet gum, green ash, cottonwoods, willows, river birch, and occasionally pines, while riverine swamp forests contain generally cypress, black gum, water tupelo, green ash and red maple. These swamps occur throughout the shoreline areas of coastal rivers.

Headwater wetlands

- **Headwater swamps** are wooded, riverine systems along small, intermittent tributary streams. Headwater swamps include hardwood-dominated communities with soil that is moist most of the year. Channels receive their water from overland flow and rarely overflow their banks.

Flat/depressional wetlands

- **Non-riverine swamp forests** are very poorly drained, non-riverine forested, or occasionally scrub/shrub, communities which are semi-permanently to temporarily flooded. Typical species include cypress, black gum, water tupelo, green ash and red maple (Sutter 1999).
- **Pocosins** are palustrine scrub/scrub communities (i.e., non-estuarine scrub/shrub) dominated by evergreen shrubs, often mixed with pond or loblolly pines. Pocosins typically occur on saturated, acid, nutrient poor, sandy or peaty soils; usually removed from large streams, and subject to periodic burning.
- **Wet forested flats** are poorly drained interstream flats not associated with rivers or estuaries. They are seasonally saturated by high water table or poor drainage. Species vary greatly but often include sweet gum and red maple. This category includes hardwood flats, pine flats, and certain managed pinelands.
- **Maritime Swamp Forests** are forested communities characterized by stunted growth due to the stresses imposed by its proximity to salt spray from the ocean. Typical vegetation includes live oak, red cedar, red maple, and swamp tupelo.

Habitat requirements

Estuarine wetlands

Salt/brackish marsh plants grow at salinities from 0.5 to >35 ppt (Wiegart and Freeman 1990). Within this salinity range, salt marsh plants persist in low-energy protected areas where the rate of sediment building (accretion) exceeds the rate of sediment loss (through erosion) or subsidence (Mitsch and Gosselink 1993). Inorganic sediments are deposited by river currents, tidal creeks and ocean overwash on and adjacent to the marsh platform (Weigert and Freeman 1990; Mitsch and Gosselink 1993). Deposition from sediment-laden creek water causes side levees of higher elevation (low marsh) and coarser particle size than the sediments in the marsh interior (high marsh).

Erosion and sedimentation are natural processes that can result in changing distributions of marsh vegetation. The rate of erosion is dependent on shoreline orientation, fetch, water depth, bank height, sediment composition of bank, shoreline vegetation, presence of offshore vegetation, and boat wakes (Riggs 2001). In general, all of the Albemarle-Pamlico estuarine system, which is a drowned river system, is in a state of shoreline recession (Riggs and Ames 2003). South of Bogue Sound, estuarine erosion is severe only in portions of drowned river estuaries such as the Cape Fear, New, and White Oak rivers, and along the ICW and navigational channels. The remaining narrow, shallow estuaries are generally not eroding, as the marshes and flats vertically accrete sediment to keep up with rising sea level. Riggs (2001) mapped the shoreline types and shoreline areas where erosion was noticeable. Shoreline erosion rates have been estimated for portions of the coast by various studies including Hartness and Stirewalt and Ingram (1974), USDA Soil Conservation Service (1975), Pearson (1977), Riggs et al. (1978), and Hardaway (1980). Their results are summarized and compared in Riggs (2001). These studies are helpful in indicating where major erosion problems are occurring.

The zonation of vegetation in salt/brackish marsh is largely determined by variations of salinity and drainage of sediment porewater (Weigert and Freeman 1990). Porewater salinity in the levees tends to remain similar to that of adjacent estuarine waters because of the frequent exchange of water and better internal drainage (due to coarser sediment) than the more isolated high marsh. Porewaters of the short cordgrass zone often are hypersaline during times of warm, dry weather, high rates of evapotranspiration, and minimal water exchange. In the high marsh, precipitation (and groundwater occasionally) creates salinities that may be low enough to support shrubs and other plants intolerant of high salinities (wax myrtle, groundsel-tree, and marsh elder). Some species are restricted in the low marsh because of high porewater salinity, frequent inundation, and high-sulfide porewaters associated with frequent inundation. Consequently, there is greater species richness in the high marsh because of the less stressful conditions.

Riverine wetlands

The development of tidal freshwater marshes is similar to that of salt/brackish marsh. Freshwater marshes have a higher number of plant species than their salt/brackish counterpart due to lower salinity in freshwater areas (Mitsch and Gosselink 1993; SAFMC 1998). Tidal freshwater marshes can also be divided into low and high zones. Species in low marshes are more fleshy and succulent (e.g., arrowheads, pickerel weed, wild rice) than those in the high marsh (e.g., cattails, reeds). Competition and inundation frequency and duration are among the most important factors determining the presence and zonation of tidal freshwater marsh, although variation in salinity along stream margins reduces the number of species (Odum et al. 1984). Tidal freshwater marsh plants are usually more sensitive to toxic levels of soluble iron, manganese, or sulfide compounds that can accumulate in tidal freshwater marsh soils and can be excluded by levels of these substances that have little effect on typical salt/brackish marsh species (Odum et al. 1984).

The plant community in nontidal (inland) freshwater marshes is very similar to its tidal counterpart. However, the hydrology of nontidal wetlands is more variable than tidal wetlands that receive regular

inundation. Water levels in inland marshes are determined by the type of water body in which they occur. Water levels in isolated marshes with a small watershed are controlled more by the balance of precipitation and evapotranspiration than anything else (Mitsch and Gosselink 1993).

Riverine swamp forests typically occur along low lying margins of rivers and lakes where they receive seasonal flooding (Wharton et al. 1982). Fish use of flooded riverine forested wetlands depends on the timing and duration of inundation. The frequency and magnitude of flooding in swamp forests depends on the land use characteristics of the watershed, bank height, the degree of stream channelization, and tidal influence. Depth and duration of flooding determine whether an area is bottomland hardwood forest or swamp forest. Swamp forests are more frequently inundated than bottomland hardwoods (DEHNR 1996), thus they are more frequently used by fish. Bottomland hardwood wetlands are generally irregularly to seasonally flooded. Overbank flooding and surface and groundwater discharge are likely sources of inundation in riverine swamp forests (Wharton et al. 1982; DEHNR 1996). The source of inundation varies with the type of river or stream. Wetlands adjacent to large rivers receive overbank flow from flood pulses or tidal flows, whereas water level in small blackwater tributaries is influenced more by groundwater discharge and local precipitation (Wharton et al. 1982). For example, the water budget of a small blackwater stream (Creeping Swamp) in coastal North Carolina showed that water loss consisted of 61% evapotranspiration, followed by baseflow (20%), overland runoff (17%) and seepage to groundwater (2%) (Winner and Simmons 1977). The relatively low input from overland flow allows the mainstem river to have more influence on small blackwater streams at high river flows. When the mainstem channel is low, water level in blackwater streams is controlled more by local precipitation. The sporadic inundation of swamps bordering blackwater streams allows temporary use by opportunistic fish at high mainstem river flows.

Headwater swamps

The requirements of headwater swamps are similar to small tributary streams referenced above. The main difference between riverine forested wetlands and headwater wetlands is their position in the watershed: headwater wetlands are the highest hydrologic points in the watershed.

Distribution

By 1994, the DCM had used GIS technology to map and classify wetlands in the 20 coastal counties using National Wetland Inventory (NWI) maps, Natural Resource Conservation Service digital soils maps, satellite imagery (1988, 1994), and hydrography maps as source data (Sutter 1999). Analyses showed there were a total of 1.3 and 2.2 million acres of riparian and non-riparian wetlands, respectively, in the CHPP management area of those counties. The classification error for wetlands was approximately 11% (Shull 1999), making the total figure for wetlands acreage in coastal North Carolina between 3.1 and 3.9 million acres.

Riparian wetlands covered 7% of the land area in coastal river basins of North Carolina in 1994, and riverine forested wetlands was the most abundant class of the three riparian wetland classes (Table 5.1). Riparian wetlands are not distributed evenly among CHPP management units (MUs) (Map 5.1a-d). The Cape Fear MU contained the largest area of riparian wetlands, followed by the Neuse and Albemarle (Figure 5.2). The greatest proportions of estuarine wetlands were in Core-Bogue, Southern Estuaries, and Pamlico MUs, whereas the Roanoke, Cape Fear, and Neuse had the highest proportion of riverine wetlands (Figure 5.2). The greatest percentage of total land cover in riparian wetlands was in the Southern Estuaries MU (13%), where the dominant wetland type was salt/brackish marsh (Table 5.1).

Salt/brackish marsh

- The total area of salt/brackish marsh in coastal North Carolina was 198,168 acres in 1994, which comprised 17% of all riparian wetland types.
- The greatest acreage (63,601 acres) of salt/brackish marsh was in the Pamlico MU.

- Salt/brackish marsh occurs in all the CHPP management units except the Chowan, Roanoke, and Coastal Ocean.

Table 5.1. Total acreage of riparian wetland types by CHPP management unit. *[Source: DCM wetland mapping (current as of 1994).]*

Management Unit	Riparian Wetlands							% of total land area
	Estuarine			Riverine			Head-water wetlands	
	Salt/Brackish Marsh	Estuarine Forest	Estuarine Shrub/Scrub	Freshwater Marsh	Bottomland Hardwood	Riverine Swamp Forest	Headwater Swamp	
Albemarle	44,758	231	8,279	4,897	8,890	140,501	2,200	**11.3**
Cape Fear	9,640	18	363	13,443	40,018	211,888	5,606	**4.9**

Roanoke	0	0	0	1,888	37,788	123,045	2,477	**7.4**
S. estuaries	21,996	66	1,115	302	1,387	9,002	824	**13.2**
Tar/ Pamlico	12,370	193	1,658	2,272	38,127	97,258	4,789	**5.8**
Total	**198,168**	**965**	**27,874**	**32,803**	**227,582**	**829,681**	**31,159**	**6.9**
% of wetland types	**14.7**	**0.1**	**2.1**	**2.4**	**16.9**	**61.5**	**2.3**	**na**

Estuarine shrub/scrub

- There was a total of 27,874 acres of estuarine shrub/scrub habitat in North Carolina in 1994, which comprised 2% of riparian wetland areas (Table 5.1).
- The greatest acreage (8,279) of estuarine shrub/scrub habitat was in the Albemarle MU.
- Estuarine shrub/scrub habitat is not present in the Chowan and Roanoke MUs.

Estuarine forests

- There was a total of 965 acres of estuarine forest in the CHPP management area, comprising less than 1% of the riparian wetlands (Table 5.1).
- The greatest acreage of estuarine forested wetlands was in the Albemarle and Pamlico MUs (231 and
- 303 acres, respectively).
- Estuarine forest wetlands are not present in the Chowan and Roanoke MUs.

Freshwater marsh

- Freshwater marsh covered a total area of 32,803 acres in 1994 and comprised 2% of these riparian

wetlands (Table 5.1).

- The greatest acreage (13,443) of freshwater marsh was in the Cape Fear MU.
- Freshwater marsh occurred in all CHPP MUs except the Coastal Ocean.

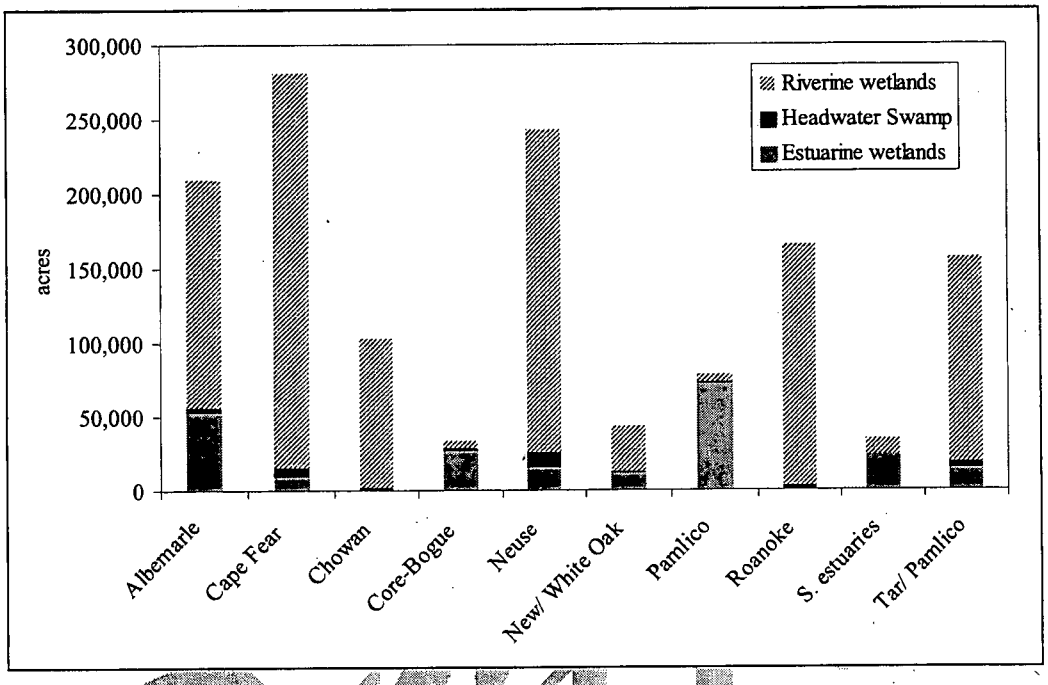

Figure 5.2. Relative amount and proportion of these riparian wetland classes among CHPP management units. *[Source: DCM wetland mapping (current as of 1994).]*

Bottomland hardwood and riverine swamp forests

- The combined total acreage of bottomland hardwood forest and riverine swamp forest in 1994 was 1,057,263, which comprised 78% of all riparian wetlands in the CHPP management area (Table 5.1).
- The greatest area (251,906 acres) of bottomland hardwood and riverine swamp forest was in the Cape Fear MU (Table 5.1).
- Bottomland hardwood forests occur in all MUs except the Coastal Ocean.

Headwater swamps

- The total area of headwater swamps in the CHPP management area in 1994 was 31,159 acres, which comprised 2% of all riparian wetlands (Table 5.1).
- The greatest acreage of headwater swamps was in the Neuse (9,283 acres), Cape Fear (5,606 acres), and Tar/Pamlico MUs (4,789 acres).
- Headwater wetlands occur in all CHPP MUs except the Coastal Ocean.

5.2. ECOLOGICAL ROLE AND FUNCTIONS

Wetlands are well known for the ecological services they provide. Wetland services improve the quality of adjacent habitats with their capacity for water control and filtration. They can also protect upland habitats from erosion. Wetlands play a vital role in providing abundant food and cover for juvenile and adult finfish and shellfish. Support and documentation of these important functions is provided in this section.

Ecosystem enhancement

The flood control and water quality benefits of wetlands have been extensively studied (Mitsch and Gosselink 1993). By spreading and slowing flood waters, wetlands decrease flooding in adjacent upland areas and downstream areas. Some wetlands can store flood waters and slowly release it to surface and groundwater systems during periods of low flow (Mitsch and Gosselink 1993). Bottomland hardwood forest along the Mississippi River before European settlement stored floodwater equivalent to about 60 days of river discharge. The storage capacity of these wetlands today has been reduced to about 12 days (Mitsch and Gosselink 1993). Consequently, flooding has increased along the lower Mississippi River. Mitsch and Gosselink (1993) concluded that wetlands reduce downstream flooding most effectively with (1) increasing wetland area, (2) increasing distance of wetland downstream, (3) increasing size of flood, (4) increasing proximity to upstream wetlands, and (5) decreasing upstream storage such as reservoirs.

An important water quality benefit of wetlands is their ability to foster settlement from sediment-laden water, resulting in deposition of suspended solids (inorganic sediment and organic matter) among the vegetation (Mitsch and Gosselink 1993). Under favorable conditions, toxic chemicals and nutrients (especially phosphorus) are also retained in some wetlands due to adsorption to sediment particles (Wolfe and Rice 1972; Mitsch and Gosselink 1993). Rooted vegetation stabilizes unconsolidated sediment, reducing erosion and turbidity in adjacent aquatic habitats. Along eroding estuarine shorelines, wetlands also provide an important buffer against wave-induced turbulence (Riggs et al. 2001). The buffering effect of wetland vegetation improves water clarity for submerged vegetation and benthic algae (Mitsch and Gosselink 1993) while also reducing sediment additions necessary for creation of new shallow water habitat (Rogers and Skrabal 2001). Consequently, both wetland and non-wetland shorelines play an important role in maintaining the function of the estuarine system. *Maintaining a natural proportion and relative position of wetland and non-wetland shorelines will be a vital component of habitat restoration and management.*

Another water quality benefit of wetlands stems from their low-oxygen soil (anaerobic or reducing). Anaerobic soils play a vital role in the nitrogen cycle by transforming ammonia and nitrate (organic waste product or fertilizer) into nitrogen gas (denitrification; Mitsch and Gosselink 1993). In agricultural watersheds receiving fertilizer-enriched runoff, denitrification plays a important role in the world's nitrogen balance (Mitsch and Gosselink 1993). Nitrogen cycling is important to fisheries because high concentrations of nitrate can be toxic to fish, and nitrogen over-enrichment can result in algal blooms and hypoxia that contribute to stress and fish kills. Even moderate hypoxia can result in death of benthic invertebrates (Diaz and Rosenburg 1995; Taylor and Eggleston 2000; Sagasti et al. 2001), a major food source for crabs and demersal fish (Taylor and Eggleston 2000). Temporary and permanent retention of nutrients, such as phosphorus, is facilitated by particle deposition and burial as well as formation of organic matter in the sediment by roots and rhizomes (Mitsch and Gosselink 1993). Forested (streamside) wetlands in agricultural drainages have been shown to remove approximately 80% of the phosphorus and 90% of the nitrogen from the water (<http://www.epa.gov/owow/wetlands/facts/fact3.html>, July 2001). Stream headwaters are the site of most active uptake and retention of nutrients in riverine systems (Peterson et al. 2001). A study of denitrification in a headwater creek (Culvert Creek, North Carolina) found that marsh vegetation had the greatest potential for denitrification, compared to marsh sediment and flashboard risers (water control structures) (<http://www2.ncsu.edu/ncsu/CIL/WRRI/reports/report317.html>, 2003). The combination of nutrient uptake and retention makes headwater wetlands very important in controlling nutrient enrichment downstream.

Mitsch and Gosselink (1993) concluded that nutrients are probably stored in salt/brackish marshes fringing estuaries with limited water circulation (i.e., back barrier sounds), whereas wetlands in funnel-shaped (trunk) estuaries export more nutrients. There is also evidence that salt/brackish marshes act as a source of nutrients during the growing season and a sink in winter and spring (Woodwell et al. 1979).

Compared to plant uptake, however, leakage of nitrogen from a Georgia salt marsh was small (Haines et al. 1979). Nitrogen uptake in salt/brackish marsh is, on average, somewhat less than in freshwater marshes (Mitsch and Gosselink 1993). The nutrients are also released by erosion and decomposition of wetland vegetation. Retention and controlled release of particles, toxic chemicals and nutrients can improve water quality downstream. Therefore, if bottomland hardwood forests or headwater swamps are lost upstream, the potential for erosion, flooding, sedimentation, algal blooms, and fish kills increases downstream (DEHNR 1996).

Productivity

Because of the abundant supply of water, nutrients, and sunlight, wetland plant communities can be one of the most biologically productive ecosystems in the world (Teal 1962; Teal and Teal 1969; Mitsch and Gosselink 1993; SAFMC 1998). Some of the high primary production (creation of organic compounds through photosynthesis) of wetland vegetation is transferred to adjacent aquatic habitats via detritus and microalgae (Peterson and Howarth 1987; Weigert and Freeman 1990; Mitsch and Gosselink 1993). However, wetland plant species vary in their rate of decomposition, with leafy, succulent, low vegetation decomposing the quickest and woody, high vegetation the slowest (Mitsch and Gosselink 1993). Therefore, production from vegetation in woody, forested wetlands is converted more slowly into detritus than vegetation in marsh wetlands with leafy, succulent vegetation. Inundated wetland plants also exude dissolved organic substances contributing to epiphytic growth on their stems and leaves (Mitsch and Gosselink 1993).

Salt/brackish marsh growth in the low marsh is limited by self-shading, where other habitat requirements are met, whereas growth in the high marsh can be affected by a number of factors, including high salinity, sulfides, scarcity of iron, and lack of nitrogen (Weigert and Freeman 1990). Accounting for phytoplankton in the water column and algae on the sediment surface, productivity of low marsh (*Spartina alterniflora*) in a Georgia tidal creek was 1,539 g carbon/m^2/yr, while production in the high marsh was somewhat lower (about 1,350 g carbon/m^2/yr) (Weigert and Freeman 1990). In North Carolina, Stroud (1976) reported somewhat higher salt/brackish marsh production in low marsh (1660 g carbon/m^2/yr), but much lower production in the high marsh (750 g carbon/m^2/yr). In both North Carolina and Georgia, above ground production was about 20% greater than below-ground production (Mitsch and Gosselink 1993).

Primary production in salt/brackish marshes is converted into fish production through several pathways. Using sulfur, carbon, and nitrogen isotopes to trace organic matter flow in the salt marsh estuaries of Sapelo Island, Georgia, Peterson and Howarth (1987) found two major sources of organic matter used in fish production: *Spartina* (detritus) and algae. The relative importance of each source is determined by the feeding mode, size, location, and trophic position of the marsh and estuarine consumers (Peterson and Howarth 1987). For example, benthic microalgae probably support herbivorous snails, whereas detritus supports sheepshead minnows, mummichogs, and their prey. Attached algae can be found on the marsh grass itself, the intertidal mudflats, and the shallow subtidal bottom near the marsh. Pinckney and Zingmark (1993) compared production rates of benthic microalgae in various bottom types in an estuarine system (North Inlet, South Carolina). Short *Spartina* marsh accounted for the greatest amount of microalgal productivity (44.6%) in the system, followed by intertidal mudflats (22%), tall *Spartina* marsh (18%), and shallow subtidal bottom (<1 m mean low water) (13%). Sand flats accounted for only 3% of the total annual microalgal production (Pinckney and Zingmark 1993).

Productivity in riverine forested wetlands in North Carolina has been reported to be much lower than in salt/brackish marsh, representing about 523-677 g carbon/m^2/yr of leaf and twig litter (Brinson 1977; Mulholland 1979). However, the total production of forested wetlands may be similar to that of salt/brackish marsh when stem growth and below ground production are taken into account. The export of detritus from these riverine forested wetlands can be significant (Mitsch and Gosselink 1993). Mulholland and Kuenzler (1979) found that organic export was higher from river basins containing more

deepwater swamps than other riparian habitats. From a Louisiana swamp forest, Day et al. (1977) measured an export rate of 10.4 g carbon/m^2/yr. By contrast, salt/brackish marshes can have an organic export rate as high as 100 g carbon/m^2/yr (Wiegert et al. 1981). However, export rates in swamp forest can vary greatly with submersion regime and temperature. For example, higher temperatures (allowing faster decomposition) and frequent inundation increase the export rate of tidal swamp forests in tidal fresh waters of the Cape Fear River.

Fish utilization

It is estimated that over 95% of the finfish and shellfish species commercially harvested in the United States are wetland-dependent (Feierabend and Zelanzy 1987). Wetlands provide numerous ecological services to coastal fishes (Table 5.2). For example, one of the most important characteristics of riparian wetlands is their combination of shallow water and thick vegetation, which provides nursery habitat for young fish. The use of wetlands by finfish and shellfish is presented first, followed by documentation of specific functions for selected species.

Draft

Table 5.2. Partial listing of wetland-enhanced fishery and forage species and stocks in coastal North Carolina. **Bolded** species show some preference for wetland habitat over other habitats documented in the text.

SPAWNING GUILD	Wetland Functions[1]					Fishery[2]	Stock Status[3]
Common name	Nursery	Foraging	Refuge	Spawning	Corridor		
ANADROMOUS & CATADROMOUS FISH							
American eel		X	X		X	X

[4] Fishery species under harvest moratorium

Salt/brackish marsh

Finfish and shellfish using salt/brackish marsh fall into several categories based on location and timing of use. Year-round residents of the marsh include small forage species such as killifish, mummichogs, sheepshead minnows, gobies, grass shrimp, bay anchovies, and silversides (SAFMC 1998). Transient species include those spawning near the marsh, but inhabiting deeper channels (i.e., river herring), and those spawned in deeper waters using marsh habitat as nursery or foraging areas. Among transient species, some prefer the edge of salt/brackish marsh (i.e., red drum, flounder) while others are found near marsh edge on unvegetated bottom (i.e., spot, croaker). Some species are not found in the marsh, but derive substantial food resources from the marsh plants as detritus (i.e., menhaden; Lewis and Peters 1994) or from microalgae produced on the marsh surface. Of fishery species in North Carolina, penaeid shrimp and red drum are considered critically linked to marsh edge habitat (SAFMC 1998)[1].

Freshwater marsh

Fishery and forage fish inhabiting tidal and non-tidal freshwater marshes include largemouth bass, bluegill, warmouth, black crappie, chain pickerel, southern flounder, white perch, mummichog, bay anchovy, inland silversides, river herrings, striped bass, and sturgeon (Mitsch and Gosselink 1993). The nature and degree of association with freshwater marsh habitat depends on the species. For example, striped bass and river herring are not only abundant along marsh edge, but also in open water areas adjacent to the marsh edge. Bluegill, black crappie, largemouth bass, and warmouth are found almost exclusively near shoreline structures such as marsh grass. Mosquitofish are an important forage species and a "mosquito control agent" closely associated with freshwater marsh habitat (Odum et al. 1984).

Bottomland hardwood and riverine swamp forest

There is a strong relationship between fishery yields and forested river floodplains (Mitsch and Gosselink 1993). A study on the Suwanee River floodplain (Florida/Georgia) found that fish production was much greater in floodplain sloughs than in the main river (Holder et al. 1970). A similar study of fish standing stock on river floodplains in North Carolina has not been conducted. Fish use of riverine forested wetlands is generally restricted to periods of seasonal inundation, which occurs mostly during winter and spring. By contrast, riverine wetlands below Lock and Dam #1 on the Cape Fear River receive regular tidal inundation (C. Hackney, UNC-W, pers. com., 2003). Seasonal flooding in riparian forested wetlands also increases the productivity of riverine systems by connecting the mainstem river with the abundant organic material found on forested floodplains (Wharton 1982; Junk et al. 1989). For example, numerous studies have shown a correlation between sunfish and largemouth bass spawning success and the timing and extent of floodplain inundation (Wharton et al. 1982). In North Carolina, seasonal high water in riverine systems generally occurs from winter to spring. Summer conditions (falling water levels, increasing temperatures, and low dissolved oxygen) exclude most fish from forested wetlands areas. Only fish adapted to low oxygen conditions continue to inhabitat wetland areas as long as they contain water (i.e., bowfin, gar, mudminnows, killifish; Wharton et al. 1982). A study on fish use of creek floodplains in North Carolina documented several common species using channels in the floodplain (Walker 1984). Those species included several small sunfish species, redfin pickerel, bowfin, brown bullheads, redear sunfish, pumpkinseed, bluegill sunfish, green sunfish, and small forage species (i.e., shiners, darters, killifish, and crayfish). Estuarine-dependent species found on river floodplains include hickory shad, blueback herring (Wharton et al. 1982), and alewife (SAFMC 1998). The tidal swamp forests in the Cape Fear estuary are also inhabited by blue crabs and other transient estuarine species (C. Hackney, UNC-W, pers. com., 2003).

Flat/depressional wetlands

Fish use of normally isolated wetlands (i.e., pocosins along the Alligator and Northeast Cape Fear rivers)

[1] More information on salt/brackish marsh can be found in the Nursery function section of this chapter.

depends on many factors. A study conducted on the Savannah River floodplain found that fish use was limited to wetlands that dried infrequently, were most connected to intermittent water bodies, and had an elevation closest to the nearest permanent water body (Snodgrass et al. 1996). Pocosins that are located directly adjacent to salt/brackish marsh or other riparian wetlands are potential fish habitat. Biotic interactions and characteristics of the wetlands had relatively less influence on fish community structure than the wetland's landscape position. The study also noted that only widespread, colonizing species were correlated with landscape position, suggesting more complicating factors controlling colonization rates (i.e., variation in water level more related to local rainfall than overflow). *As sea level continues to rise and low-lying pocosins near coastal North Carolina waters transition to marshes, they will become more important as primary nursery areas for estuarine-dependent fish (Brinson 1991). Therefore, a similar study should be conducted in North Carolina to determine what pocosin areas are actually used by fish, and the contribution of those fish to overall production in the estuary.*

Specific biological functions

Nursery

The large expanses of shallow water and thick vegetation found in riparian wetlands provide abundant food and cover for larval, juvenile and small organisms (Graff and Middleton 2003). Nursery habitat is not only provided by the dense structures, but also by the shallow depth of water itself, which provides refuge from aquatic fish predators (review in Rozas and Odum 1987). The aversion to shallow water among large, deep-bodied aquatic predators is a common behavior, which indirectly protects smaller fish.

Salt/brackish marsh

Along with the shallow soft bottom areas they border, salt/brackish marshes along the North Carolina coast are probably the most recognizable nursery habitat for estuarine-dependent species. The majority of Primary and Secondary Nursery Areas designated by the MFC are located in soft bottom areas surrounded by salt/brackish marsh. Even though salinity and transport mechanisms are the key physical factors affecting the species composition in nursery habitats in Pamlico Sound and its tributaries (Ross and Epperly 1985; Noble and Monroe 1991; Ross 2003), marsh wetlands are a vital component of estuarine nursery habitat. Minello et al. (2003) concluded that the relative nursery value of salt marshes in Atlantic coast estuaries appears to be higher than open water, but lower than submerged aquatic vegetation.

Most of the juvenile fishes found in salt/brackish marsh nurseries are comprised of species spawned offshore during winter. The larvae are subsequently transported through inlets and into estuarine waters where they settle in the upper (low salinity) or lowermost (high salinity) reaches of estuarine creek systems (Ross 2003). The peak of juvenile settlement generally occurs in spring through early summer, although the peak is correlated more with water temperature (Ross and Epperly 1985). Settlement in upper reaches is particulary beneficial to spot and croaker, where growth and survivorship are enhanced compared to lower reaches (Ross 2003). If movement to general regions of the estuary is largely passive (Pietrafesa et al. 1986; Pietrafesa and Janowitz 1988), the viability of spot and croaker stocks could be reduced by hydrodynamic conditions resulting in more settlement to lower regions of the estuary (Ross 2003). This settlement pattern could also occur in other estuarine-dependent species.

According to DMF's juvenile abundance survey data, the dominant species in high salinity marshes behind the Outer Banks and Core Sound include pinfish, pink shrimp, black sea bass, gag, pigfish, red drum, gulf flounder, and summer flounder (Noble and Monroe 1991). However, the primary nursery habitat in these areas is submerged aquatic vegetation. Juvenile spot, brown shrimp, striped mullet, and southern flounder are abundant along the western shores of Pamlico and Core sounds and their tributaries (Epperly and Ross 1986; Noble and Monroe 1991). In the Newport River estuary, juvenile southern flounder showed a distinct preference for marsh edge habitat over other habitats, but only during fall (Walsh et al. 1999). The juvenile southern flounder were most abundant in more turbid, upper regions of

the estuary.

During spring through fall, brackish marshes in the Albemarle/Pamlico estuary are dominated by juvenile Atlantic menhaden, striped mullet (Epperly and Ross 1986), silversides, anchovies (Nelson et al. 1991) and more demersal species such as Atlantic croaker, brown shrimp, blue crab, and southern flounder (Noble and Monroe 1991). In higher salinity marshes of the Pamlico Sound, spotted seatrout, weakfish, silver perch, and red drum are also abundant (Noble and Monroe 1991). Juvenile red drum reach their highest abundance in brackish marsh (Tagatz and Dudley 1961; Nelson et al. 1991; C. Peterson, UNC-CH, pers. com., 2003). Fish use of low salinity (brackish) marsh habitat in estuaries of North Carolina was studied by Rozas and Hackney (1984), who found a combination of freshwater and estuarine species in low-salinity, intertidal creeks. The most abundant species were spot, grass shrimp, bay anchovy, and Atlantic menhaden. They also reported three seasonal peaks in abundance in low salinity marshes: (1) spring peak with influx of juvenile spot, Atlantic menhaden, Atlantic croaker, and southern flounder; (2) summer peak of grass shrimp; and (3) fall peak of bay anchovies and grass shrimp.

A study in Galveston Bay, Texas, found that juvenile brown shrimp, white shrimp, blue crab, spotted seatrout, and southern flounder were most abundant along salt/brackish marsh edge habitat compared to inner marsh, shell bottom, SAV, and shallow, non-vegetated bottom (Minello 1999). In another Texas estuary, low marsh supported higher abundances of brown shrimp, blue crabs, daggerblade grass shrimp, white shrimp, and striped mullet, although there was little difference between low and high marsh for white shrimp and striped mullet (Rozas and Zimmerman 2000). Resident estuarine species, such as gulf killifish and sheepshead minnow, were most abundant in high marsh.

Habitat types derived from salt/brackish marsh (i.e., peat blocks) can also provide important nursery habitat for certain species. Peat blocks are generally found along eroding marsh shorelines, where they serve as firm substrate for the attachment of sessile invertebrates and refuge for juvenile blue crabs in western Pamlico Sound (D. Eggleston, NCSU, pers. com., 2001). Szedlmayer and Able (1996) found that, in a New Jersey estuary, juvenile black seabass were more abundant in sponge-peat habitats (associated with eroding marsh) compared to eelgrass beds, upper estuary, subtidal creeks, marsh channels, and open bay areas.

Freshwater marsh

Studies documenting the use and significance of freshwater marsh for larval and juvenile fish in North Carolina are lacking. Freshwater marshes comprise only a very small portion of riparian wetlands in coastal North Carolina. A study conducted in Virginia found that larvae and juvenile fish represented 79% and 59% of the total number of fish collected at tidal freshwater and salt marsh sites, respectively (Yozzo and Smith 1997). McIvor (1987) found reduced predation by large carnivorous fish in the shallow water (<3ft or <1m) of freshwater tidal creeks, possibly due to unfavorable water quality, the physical constraints of shallow water, and/or increased predation from predatory birds (i.e., herons).

Bottomland hardwood and riverine swamp forest

Forested wetlands are important nursery areas for anadromous and resident freshwater species along coastal rivers and creeks in North Carolina (Wharton et al. 1982; DMF 2000c). Forested wetlands are also important for some transient estuarine species (i.e., spot, croaker, southern flounder, blue crab) in the lower Cape Fear River (Mallin et al. 2001c; C. Hackney, UNC-W, pers. com., 2003). The timing and extent of flooding are critical to fish use of bottomland hardwood and riverine swamp forest. Larval and juvenile river herring have been collected near flooded riverine wetlands in North Carolina (DMF 2000c). Studies of larval fish abundance and diversity on Mississippi River floodplains suggested that nearly 50% of fish species inhabiting the river used the floodplain as a nursery (Gallagher 1979). Unchannelized sections of the Missouri River produced 2 to 2.5 times more fish than channelized sections (Groen and Schmulbach 1978). In general, vegetated shoreline inundation during spring and early summer has been

correlated with increased year-class strength of largemouth bass, sunfish, and yellow perch (Nelson and Walberg 1977; Strange et al. 1982; Ploskey 1986).

Foraging

Salt/brackish marsh

Few aquatic species feed directly on living plant tissue in salt/brackish marsh (i.e., periwinkle), and their productivity is very low compared to that of detritivores and consumers of microalgae (Weigert and Freeman 1990; Steel 1991; SAFMC 1998). However, biotic interactions with primary consumers can result in degradation or loss of wetlands. Recent study results from the southeastern United States suggest that blue crab predation on plant-eating snails may prevent the snail from overgrazing the marsh grass (Silliman and Bertness 2002).

Detrital and bacterial production from salt/brackish marsh is one of the highest per unit area of any ecosystem in the world (Wiegert and Evans 1967). Slow-moving or sessile species residing in salt/brackish marsh and contributing to secondary production include fiddler crabs, mud snails, amphipods, oysters, clams, and ribbed mussels (Weigert and Freeman 1990). Based on data from Georgia marshes, biomass of these resident species exceeded 15 g carbon/m^2, and consisted of 80-200 fiddler crabs, 400-700 periwinkle snails or mud snails, and 7-8 mussels (Weigert and Freeman 1990). The resident estuarine fishes (i.e., killifish, grass shrimp, sheepshead minnow) are an important link between estuarine production and transient predatory fish populations (Weigert and Freeman 1990; Kneib 1997). Salt-brackish marsh edge also provides important feeding areas for blue crabs, red drum, flounder, seatrout and other large predators searching the edge of complex structure near deeper water, as illustrated by greater predation on grass shrimp with increasing depth in shallow estuarine water (Clark et al. 2003).

It has been estimated that 45% of salt marsh production is exported to the estuarine system in the form of detritus, dissolved organic matter, and transient nekton (i.e., grass shrimp and killifish; Teal 1962). The biomass of secondary production going in and out with the tide (fish, shrimp) is less well known than resident species biomass (Kneib and Wagner 1994). The exported production of brown and white shrimp is probably the best known and most significant to coastal fisheries (Turner 1977; Weigert and Freeman 1990). The estimated yield of shrimp from North Carolina was 107 lb per acre of intertidal vegetated bottom (Turner 1977), where intertidal vegetation included "salt marsh macrophytes, *Spartina* spp. [and] *Juncus* spp." However, recent research suggests that wetlands vary greatly in their role as exporters or importers of organic matter (Weigert and Freeman 1990). This variation could be the result of variable erosion or deposition rates among seasons or wetland areas.

Freshwater marsh

Compared to salt/brackish marsh, most living vegetation in freshwater marshes can be more readily consumed by insects, crayfish, muskrats, waterfowl, and carp (Mitsch and Gosselink 1993; SAFMC 1998). However, herbivory is still minor in freshwater marshes (Mitsch and Gosselink 1993). Together with phytoplankton and benthic algae, organic matter from the emergent vegetation is the source of primary production in freshwater marshes. The export of this production (in the form of particulate detritus) to other systems is less understood than that of salt marshes (Mitsch and Gosselink 1993), but is probably similarly affected by the rates of erosion and water exchange between wetlands and open water systems. Because many freshwater marshes in North Carolina generally occur in slow-moving, backwater areas, export of detritus is probably less significant compared to salt marshes.

The detritus that remains in the marsh provides food for meio- and macrobenthic communities consisting of nematode worms, chironomid fly larvae, mysids, snails, and amphipods (Odum et al. 1981; Mitsch and Gosselink 1993; SAFMC 1998). The macrobenthic community, in turn, provides abundant food for small fish, grass shrimp, crayfish, crabs, and waterfowl. Large fish feeding within the marsh include chain pickerel, bowfin, and gars (Odum et al. 1981). Many other large, aquatic predators (i.e., largemouth bass,

crappie) feed along the edge of freshwater marshes where there is deep water nearby for refuge (Odum et al. 1981).

Bottomland hardwood and riverine swamp forest

Although riverine forests contain vast stores of organic matter, much of it is not rapidly converted into particulate organic matter for secondary production (Mitsch and Gosselink 1993) because woody material and leaves break down more slowly than succulent vegetation in marshes. In spite of this, riverine forested wetlands still produce abundant invertebrate food, such as copepods, ostracods, amphipods, isopods, oligochaetes, flatworms, crayfish, and terrestrial insects (Wharton et al. 1982; Mitsch and Gosselink 1993). Fish species and life stages adapted for feeding in riverine swamp forests include adult mosquitofish, gar, bowfin, carp and chain pickerel, along with early life stages of many other species (Wharton et al. 1982; Mitsch and Gosselink 1993). Other species, such as largemouth bass and catfish, are opportunistic predators within the flooded forest.

Refuge

Adult or small aquatic organisms find refuge from predators and adverse weather conditions on and among the dense leaf canopies found in salt/brackish and freshwater marshes (Mitsch and Gosselink 1993; SAFMC 1998; Graff and Middleton 2003). Many small resident species, such as grass shrimp and killifish, reside within emergent stands of vegetation (Pattilo et al. 1997; SAFMC 1998; Minello 1999; Rozas and Zimmerman 2000). A recent study on predation risk and prey distribution in shallow-water estuarine habitats found that predation on grass shrimp increased with increasing depth during the day, and decreased across all depths at night (Clark et al. 2003). The study results highlight the importance of a refuge from predation during the daytime and a relaxation of predation at night. Large, somewhat less mobile organisms also find refuge in the vegetation. For example, Micheli and Peterson (1999) found that adult blue crabs utilized marsh edge habitat in preference to unvegetated, open water habitat in a North Carolina estuary, presumably as refuge from predation.[2]

The structure provided by freshwater marsh vegetation and forested wetland margins provides excellent refuge for sunfish, crappie, largemouth bass, and other ambush predators, as well as slow-moving benthic invertebrates (e.g., crayfish). Numerous studies have documented the vegetated habitat preference of largemouth bass, bluegill, and other freshwater ambush predators (review in Savino and Stein 1989).

Spawning

The stems and leaves of wetland vegetation provide a surface for attachment of eggs. The combination of egg-laying structures, abundant food and relative scarcity of predators (Power et al. 1995) in seasonally flooded wetlands makes them an ideal spawning area. River herring are an important coastal species that spawn adhesive eggs in flooded swamps, oxbows, and along stream edges (Wharton et al. 1982; DMF 2000c). Spawning of river herring in North Carolina occurs during elevated spring flows from March through May in small tributaries (DMF 2000c).

The structural complexity of marsh vegetation and intertidal submersion regime in salt/brackish marsh provides spawning habitat for forage species such as killifish (including mummichogs), silversides, gobies, and grass shrimp (Anderson 1985; Pattilo et al. 1997). The number of species spawning in salt marsh habitat is low compared to the number of estuarine species spawning offshore and in deep channel habitat (Table 2.3). Nevertheless, many of the species spawning in wetlands are also important food items for transient fishery species.

[2] The refuge function of marshes for juvenile species is discussed in the nursery function section.

Corridor and connectivity

Within the marsh, elevation and proximity to open water are important influences on the distribution of fish. Rozas and Odum (1987) found that shallow water and greater distance from deep water typically meant lower abundance of large predatory fish (Rozas and Odum 1987). Marsh edge is also more utilized when adjacent to SAV or shell beds where small organisms can take refuge at low tide (Rozas and Odum 1987; Irlandi and Crawford 1997; Micheli and Peterson 1998). Increased utilization is possible because small organisms need to move only a short distance to return to the marsh at high tide. Rozas and Odum (1987) compared fish and shellfish densities in tidal creeks with and without adjacent SAV beds. They found that grass shrimp numbers greatly declined when artificial SAV was removed from a tidal creek. However, fish numbers (mostly mummichogs and banded killifish) were not significantly reduced. The results suggest a higher relative importance of wetland vegetation near SAV beds for grass shrimp. Irlandi and Crawford (1997) found that pinfish were more than twice as abundant in intertidal marshes adjacent to SAV beds than in marshes adjacent to completely unvegetated bottom. The movement of pinfish between the intertidal marsh and subtidal grass beds could provide an important link in the transfer of secondary production from the marsh to adjacent aquatic habitats, and visa versa. Micheli and Peterson (1998) found that marsh edge provides corridor function by facilitating the access of blue crabs to oyster reefs and enhancing the intensity of predation on smaller macroinvertebrates. Isolated oyster reefs had higher densities of those smaller macroinvertebrates. *These studies show the importance of considering optimal locations for SAV and wetland restoration/creation projects.*

Functional significance

Functional value of wetlands was incorporated into DCM's North Carolina Coastal Region Evaluation of Wetland Significance (NC-CREWS), which is a GIS wetland functional assessment model. The primary objective of the NC-CREWS wetland functional assessment is to provide users with information about the relative ecological importance of wetlands for use in planning and the overall management of wetlands. Thirty-eight separate wetland functions were used to evaluate each mapped wetland area within the 20 coastal counties. Each wetland is given a rating of either "Exceptional", "Substantial", or "Beneficial" Functional Significance. The overall rating was based on individual ratings for non-point source function, floodwater cleansing, landscape and watershed attributes, surface runoff storage, floodwater storage, shoreline stabilization, terrestrial wildlife habitat functions, and aquatic life habitat functions (Sutter et al. 1999). NC-CREWS provides an excellent rating system, but it was not specifically developed to locate the best habitat for coastal fisheries. Wetland properties such as primary production, structural complexity, depth and submersion regime were not included in this particular model. However, the 'aquatic life habitat functions' component of CREWS provides an area within which coastal fish habitat can be found. The aquatic life habitat function of NC-CREWS include anadromous fish, other fish species, and amphibian/invertebrate habitat (Sutter et al. 1999).

The NC-CREWS categories corresponded fairly well to riparian and non-riparian habitat categories used in CHPPs. Riparian wetlands included the following DCM wetland types: salt/brackish marsh, freshwater marsh, estuarine shrub/scrub, bottomland hardwood, riverine swamp forest, headwater swamp, and estuarine forest. Most intact riparian wetlands were rated "Exceptional" in function (Figure 5.3). The majority of non-riparian wetlands were rated as "Substantial." There were virtually no riparian wetlands in the "Beneficial" significance category. *The significance of riparian wetlands further justifies the need to enhance their protection.*

	Exceptional	Substantial	Beneficial
Non-riparian	356,747	877,052	34,170
Riparian	463,479	194,594	87

Figure 5.3. Results from North Carolina Coastal Region Evaluation of Wetland Significance (NC-CREWS) in CAMA counties grouped by CHPP riparian and non-riparian wetland categories.

5.3. STATUS AND TRENDS

Status of wetland habitat

Various estimates have been made of the original extent of North Carolina's wetlands. The DWQ and North Carolina Water Resources Research Institute staff have examined hydric soils from the published and draft county soil surveys (DWQ 2000a). These studies estimate that North Carolina had about 7.2 million acres of wetlands prior to colonization. Of that original extent, 95% was in the Coastal Plains. In another study, Dahl (1990) estimated that by the mid-1980s, only about one-half of North Carolina's original wetlands remained. The trend in wetland loss for North Carolina mirrors national trends (Dahl 1990).

According to DWQ (2000a), approximately 66% of North Carolina's original wetland extent remain and 83% of its original salt marsh, bottomland hardwood, and swamp forest (Table 5.3). However, the 83% figure is only a rough estimate because the DWQ study did not distinguish between depressional and riverine swamp forest. Pocosins have suffered even greater losses (48% remaining from the 1950s). The figures also do not account for wetland losses after 1993. The amount for remaining wetlands in North Carolina will be updated later in this chapter with more recent permit statistics.

Table 5.3. North Carolina wetland acreage estimates. *[Source: NC Division of Water Quality 305(b) report (DWQ 2000a)]*

Wetland type		Wetland Acreage				
		Original Extent[1]	1990's	Change	% remaining	Reference[2]
Non-riparian	Pine savannah	3,643,000	28,000	-3,615,000	1%	Leonard, pers. com.
	Pocosin	1,366,000	655,000	-711,000	48%	DWQ 1993
	Wet pine flatwood	0	2,212,000[3]	2,212,000		DWQ 1993
Riparian	Bottomland hardwood	1,481,000	1,207,000	-274,000	81%	DWQ 1993
	Salt marsh	209,000	183,000	-26,000	88%	Cashin 1992
	Swamp forest	476,000	413,000	-63,000	87%	DWQ 1993
TOTAL		7,175,000	4,706,000	-2,469,000	66%	DWQ 1993

[1] Based on descriptions of native vegetation found on hydric soils from SCS county soil surveys from the 1950s.

[2] These reference did not use the same methods and are not directly comparable.

[3] Based on original extent of pine savannahs.

The DCM wetlands types use three modifiers to indicate human disturbance: 1) partially drained, 2) cutover, or 3) cleared. These modifiers were not meant to account for all wetlands modified or "lost." The inclusion of modifiers was simply a way to show how some of the wetlands remaining today have been degraded or modified (M. Lopazanski, DCM, pers. com., 2003). According to U.S. Fish and Wildlife Service's National Wetlands Inventory maps, partially drained wetlands are, or have been, partially ditched/drained. Cutover wetlands are wetland areas in which satellite imagery from 1994 indicates a lack of vegetation where it was present in 1988. Cleared wetlands are areas containing hydric soils for which satellite imagery indicated a lack of vegetation in both 1988 and 1994. Cutover wetlands have likely retained wetland hydrology and soil characteristics, while cleared and drained wetlands are probably no longer functional wetlands.

Using the DCM modifiers for human disturbance, more non-riparian wetlands have been lost than riparian wetlands. As of 1994, 98,773 and 387,498 acres of riparian and non-riparian wetlands, respectively, were mapped as degraded or modified (Tables 5.4 and 5.5). Among riparian wetland types, riverine swamp forests were most often mapped as modifed by drainage, followed by salt/brackish marshes, and bottomland hardwood forests (Table 5.4 and Maps 5.1a-d). A quantifiable trend in wetland degradation is apparent for cutover wetlands. During 1988-1994, the rates of cutover for riparian and non-riparian wetlands were 2,919 and 6,719 acres/year, respectively (DCM, unpub. data). Although wetland hydrology and soil are maintained in these areas, the trees will take years to recover.

[2] Impacted from 1988-1994

Within DWQ coastal river basins, Clean Water Act section 401-permitted wetland impacts over a period of four fiscal years (1997-2001) indicate a potential conversion of 3,817 wetland acres to non-wetland uses (Figure 5.4). Losses in fiscal years 1999/2000 and 2000/2001 were relatively small compared to 1997/1998 and 1998/1999. The relatively large losses in those earlier years resulted from two large projects (Buckhorn Reservoir in Wilson County and Global Transpark in Lenoir County). However, it should be noted that section 401 water quality certifications (from DWQ) precede section 404 permits (from the U.S. Army Corps of Engineers or COE) that may never be issued. In addition, some permitted impacts never occur. There were an additional 11,580 acres of pocosin wetland (non-riparian) lost after repeal of the federal Tulloch Rule[3]. However, most of this acreage had its hydrology restored through an intensive state and federal enforcement effort. There are also an unknown number of wetland acres lost

[3] See "Land use and wetland conversion" section for more information

each year from unauthorized projects and small projects not requiring confirmation by DWQ. Thus, the amount of impacted wetland acres may be underestimated. The DWQ is working to resolve the issue of tracking unauthorized and cumulative, small impacts (DWQ 2000a).

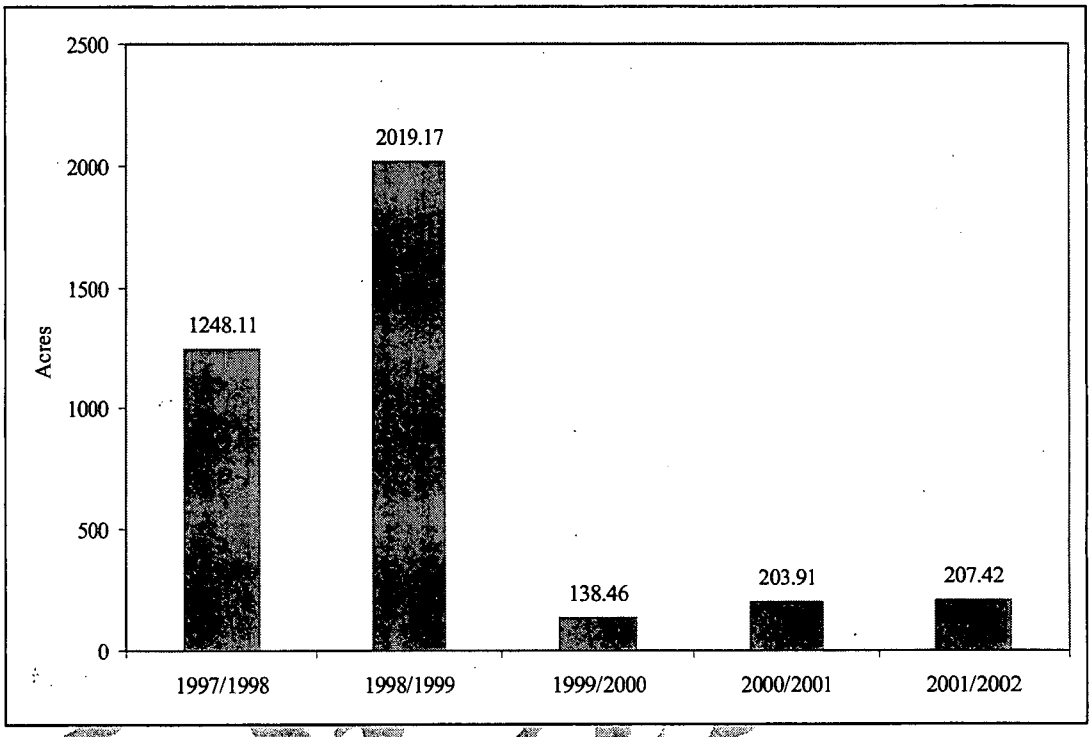

Figure 5.4: Total DWQ 401 Permitted Wetland Impacts (acres) during 1997-2002 in the seven Coastal river basins (excluding the Lumber riverbasin).*

* These data are for permanent wetland loss and do not include impacts from CAMA, Corps of Engineers Nationwide Permits 12 and 33, and Corps of Engineers Regional General Permit 030 since these impacts are temporary or are impacts to water (e.g., drainage).

In addition to conversion caused directly by humans, wetlands are also being lost to erosion resulting from sea level rise and shoreline hardening (Riggs 2001). Based on a recent study of 21 field sites and then extrapolated to the entire length of estuarine shoreline in northeastern North Carolina, annual wetland losses are approximately 802 acres/year, most of which are mainland brackish marsh habitat (Riggs and Ames 2003). When the cumulative effects of permitted wetlands impacts from 1997 to 2001, unpermitted wetland impacts (after repeal of Tulloch Rule), estimated coastal erosion loss from 1993 to 2001, and total estimated wetland losses prior to 1993 (DWQ 2000a) are added together, the total loss of wetlands in DWQ coastal river basins could be as much as 2,491,515 acres (1993-2002). This total estimated wetland loss still leaves 65% of the estimated original extent of wetlands in North Carolina (DWQ 2000a). However, this figure does not account for wetlands gained through restoration or creation, either by natural processes or restoration/creation effort. It also does not account for losses between 1993 and 1997 that were not attributable to erosion.

Status of associated fishery stocks

Of the partial list of 20 fishery species and at least 23 fish stocks in Table 5.2, the status of four species is unknown (DMF 2003). Of the 18 stocks whose status is known, four (22%) are Overfished, six (33%) are Concern, and eight (44%) are Viable. Of the nine fishery stocks with higher relative abundance in wetlands, two are Overfished, three are Concern, and four are Viable. Based on Figure 5.5, there are an

approximately equal number of Viable and Concern-Overfished stocks. However, there are a large number of additional species within the unknown category. The two wetland-enhanced[4] stocks listed as Overfished are river herring (alewife and blueback herring in Albemarle Sound) and southern flounder. Wetland-enhanced species of concern include blue crab, striped mullet, and red drum.[5]

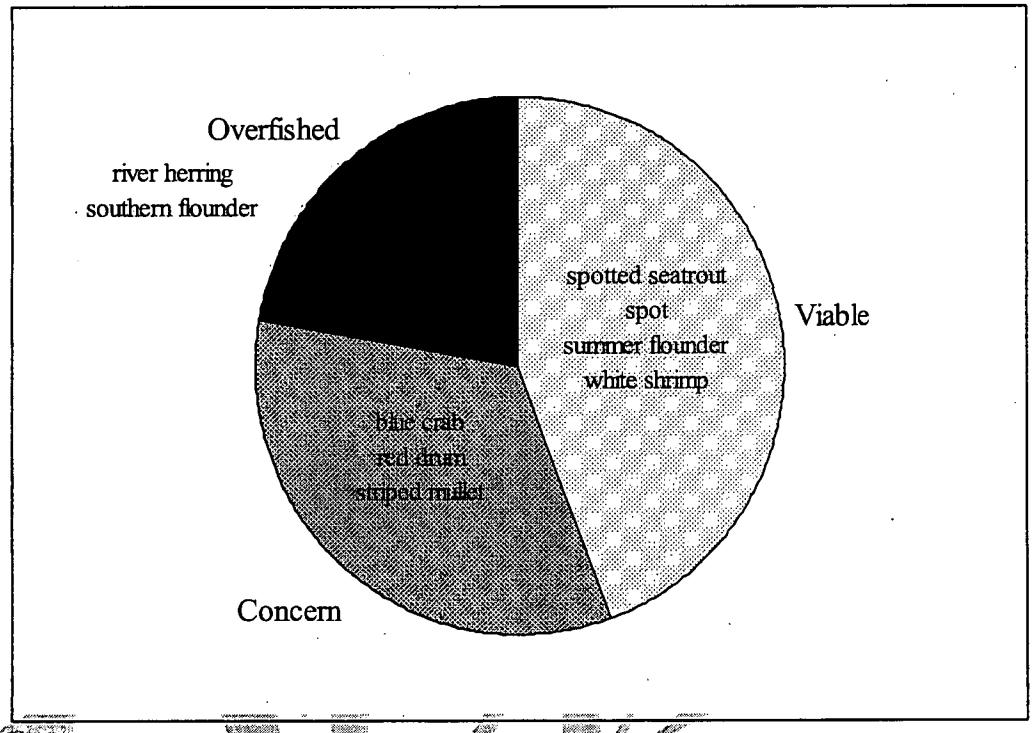

Figure 5.5 Percent of wetland-enhanced fish stocks classified as Overfished, Concern, or Viable in the 2003 North Carolina Division of Marine Fisheries stock status report (DMF 2003a).*

* Refer to Table 5.2 for list of wetland-enhanced fishery species)

While most of the concern over declining fish stocks has focused on overfishing, habitat loss and degradation can also prevent recovery or make a stock more susceptible to overfishing. For example, impassable obstructions of migratory corridors to spawning grounds can prevent stock recovery despite fishing restrictions. In other cases, regional reductions or loss of one habitat can make a stock more susceptible to overfishing by reducing the diversity or total amount of suitable habitat available. *A strategy for enhancing fisheries, as required by the Fisheries Reform Act of 1997, must therefore involve both habitat protection/enhancement and prevention/reduction of overfishing.*

Wetland restoration

The loss of wetlands and need for alternative pollution control methods prompted restoration/creation efforts beginning in the late 1980s and early 1990s (Mitsch and Gosselink 1993). Actual restoration of wetlands is accomplished through compensatory mitigation and voluntary initiatives. The purpose of compensatory mitigation is to replace wetland functions that are lost through permitted impacts to wetlands (WRP 2002). Many wetland restoration projects involve simply restoring the natural hydrologic condition, while others include greater design considerations. Depending on the purpose of restoration/creation, design considerations include hydroperiod, nutrient/pollutant loading rates, seasonal

[4] Wetland-enhanced species are those showing some documented preference for wetland habitat.

[5] A more detailed evaluation of wetland-enhanced species and their status can be found in the Chapter 6 (i.e., nursery area statistics).

flood pulses, flow patterns, water retention times (Mitsch and Gosselink 1993), and/or soil type.

While there have been many successful projects implemented nationwide, there have been failures attributed to lack of proper hydrology (Mitsch and Gosselink 1993). More recent studies in North Carolina found that mitigation sites restored by the North Carolina Department of Transportation (DOT) relied too much on hydrologic criteria, leading to reduced survivorship of planted seedlings in some excavated areas with non-wetland soil (Rheinhardt and Brinson 2002). They also found that reference sites were rarely utilized in measuring the success of restoration. Presently, all DOT monitoring is stopped after permit conditions are satisfied. With these considerations in mind, it will be difficult to determine gains in wetland acreage. *Rheinhardt and Brinson (2002) encourage long-term monitoring of restoration projects using success criteria based on hydrology, soil, and vegetation characteristics at established reference sites.*

North Carolina Wetlands Restoration Program

The North Carolina Wetlands Restoration Program (WRP) is part of state's Ecosystem Enhancement Program[6]. The WRP's mission is to restore, enhance, preserve and create wetlands, streams, and riparian buffer areas throughout North Carolina's 17 river basins. To accomplish this mission, the WRP works closely with the DWQ and other resource agencies to identify watersheds (14-digit hydrologic units) in each river basin that exhibit both the need and opportunity for restoration. These areas are called "Targeted Local Watersheds" and receive priority for WRP planning and restoration project funds. Based primarily on water quality, habitat, land cover, and public comment, staff identify Targeted Local Watersheds that are believed to be the best areas for the program to implement wetland, stream, and riparian restoration projects, and nutrient reduction projects. The goal is to concentrate multiple projects within small watersheds to address real watershed degradation symptoms instead of isolated problem areas scattered more broadly across a basin or larger watershed. This focus works toward implementing long-term watershed restoration and protection benefits. The WRP encourages other government entities and funding organizations to consider implementing watershed and habitat improvement projects within these areas as well as maximize state, federal and local funding sources based on multiple watershed planning objectives. Multiple complementary projects focused in small watersheds will provide the greatest ecological benefit to North Carolina's streams, rivers, lakes, estuaries, and wetlands. This approach also helps maximize program funds and programmatic benefits, creating an environment for partnership and collaboration among various state, federal and local programs.

Compensatory mitigation is often required with the issuance of a 401 Water Quality Certification and/or Section 404 permit to impact wetlands. However, not all project impacts are mitigated with the creation or restoration of wetlands. Based on compensatory mitigation requirements, permittees may choose to conduct the compensatory mitigation themselves, request to make a payment to the DENR Wetlands Trust Fund for Compensatory Mitigation, or purchase credits from private mitigation banks (if the impacts occur within their mitigation service area). Donation of land for wetlands restoration or creation also satisfies wetland mitigation requirements [EMC rule 15A NCAC 02R .0403 (e)(1-2)]. Land donations preserving wetlands do not satisfy the rule. *Land acquisition for preservation should also be an option for wetlands mitigation. However, the amount of land preserved should be more than the area*

[6] See "Recent trends" subsection under "Land use and wetland alteration" for more information on North Carolina's Ecosystem Enhancement Program.

[7] The data presented in this section are based on the Division of Water Quality's Wetlands/401 Unit's Water Quality Certification Database. This database tracks wetland and streams losses that are authorized through the issuance of a 401 Water Quality Certification. Issuance of a 401 Water Quality Certification is required before the Corps of Engineers can issue a Section 404 Permit authorizing the fill or alteration of wetlands and/or streams. Although in the majority of cases the impacts authorized by the 401 Water Quality Certification are consistent with the impacts authorized by the Section 404 Permit, the amount of impact authorized by the Section 404 Permit may be less than that authorized by the 401 Water Quality Certification and, in some cases, a Section 404 Permit may never be issued. In addition, the authorized impacts may not occur during this fiscal year and in some cases may never occur. The DWQ is increasing its efforts to monitor and track the impacts that actually occur.

impacted because the preservation will not offset the adverse impact. Land preservation is already an option for Department of Transportation projects under the new Ecosystem Enhancement Program.[8]

The WRP is required by statute to report on both compensatory and non-compensatory (i.e., non-regulatory) restoration work accomplished in North Carolina annually. In fiscal year 2001-2002, eighty-one 401 Water Quality Certifications issued statewide required wetland or stream mitigation. Of those, 69% were satisfied through payment to the Wetlands Trust Fund. Compensatory mitigation requirements for 7% were satisfied through payment to private mitigation banks, while the remaining 23% conducted compensatory mitigation on-site. The amount of compensatory mitigation in North Carolina coastal river basins during fiscal years 1999-2002 was approximately 650 acres (WRP 2000, 2001, 2002) (Table 5.6). During that same time period, there were 550 acres of wetlands impacted in coastal river basins[9]. There is also some voluntary creation or restoration of wetlands. During fiscal years 1999-2002, 17.25 acres of wetlands were voluntarily restored or created in coastal river basins through non-regulatory restoration practices (i.e., North Carolina Coastal Federation projects funded by Clean Water Management Trust Fund).

Table 5.6. The amount (acres) of compensatory mitigation and non-regulatory gains (voluntary restoration/enhancement) in coastal river basins from 1999-2002. *(Sources: WRP 2000, 2001, and 2002)*

Fiscal year	Non-regulatory Gains-Restoration/Creation	Compensatory mitigation	Total
1999/2000	9.25	150.40	159.65
2000/2001	2.00	288.60	290.60
2001/2002	6.00	195.65	201.65
TOTAL	17.25	634.65	651.90

The WRP evaluates the costs of restoration projects on an annual basis. These costs can vary based on site conditions and restoration methods. Based on two riparian wetland projects in fiscal year 2001-2002, the cost of restoration in 2002 was $20,000-25,000/acre (WRP 2002). The cost includes site identification, site acquisition, project design, construction management, site restoration, post monitoring, and long-term management. The cost of restoring 4.11 acres of coastal wetlands in 2002 was even higher at $101,148/acre.[10]

The rate of wetland loss documented by 401 permit records does not account for functional equivalency, which is the replacement of full ecological functions specific to a wetland type. Currently, wetlands losses and gains are tracked on an acre-for-acre basis. The wetland type lost is not always mitigated by the creation of a similar wetland type. In fact, there is little consideration for maintaining a natural mix of wetland types on the landscape. *Rheinhardt and Brinson (2002) recommended the tracking of restoration efforts by river basin and hydrogeomorphic class so that restoration can maintain a balanced distribution of classes on the landscape.* For example, the loss of riverine wetlands in the Neuse River basin should be mitigated by the creation or restoration of riverine wetlands in the Neuse River basin. The new Ecosystem Enhancement Program is tracking restoration efforts associated with Department of

[8] See "Recent trends" subsection under "Land use and wetland conversion" later in this chapter for more information.

[9] The total number of wetlands impacted includes impacts of less than one acre. Impacts of less than one acre do not require compensatory mitigation as a condition of the 401 Water Quality Certification, though they may result in a substantial loss of wetland resources (WRP 2002).

[10] For additional information regarding 401/404 compensatory mitigation requirements, please visit DWQ's website at <http://h2o.enr.state.nc.us/ncwetlands/>. For additional information concerning the WRP, please visit <http://h2o.enr.state.nc.us/wrp/>.

Transportation projects.[11]

Other initiatives

Federal, state, local, and private organizations and individuals conduct voluntary initiatives. The Wetlands Reserve Program of the Food, Agriculture, Conservation, and Trade Act of 1990 authorized the U.S. Department of Agriculture (USDA) to purchase easements from landowners who agree to protect or restore wetlands. The goal of USDA's Pilot Wetlands Reserve Program was to restore one million acres of cultivated crops to wetlands by 1995 (Bales and Newcomb 1996). The USDA pays 75% of the restoration cost to landowners, and NRCS and FWS assist in completing the restoration plans. As of 2001, there were more than 6,500 restoration projects nationwide that encompassed nearly 1,075,000 acres (NRCS 2002). By 1992, there were about 15,000 acres of cultivated land enrolled in the North Carolina program (Bales and Newcomb 1996). By 2002, total program enrollment in North Carolina had exceeded 26,000 acres (NRCS 2003). Project costs vary throughout the country. In 2001, the average cost of purchasing and restoring a permanent easement was approximately $1,200 per acre. The average cost of purchasing and restoring a 30-year easement was around $770 per acre. Restoration cost-share agreements, which do not include easement acquisition costs, averaged around $450 per acre (NRCS 2003).

The Conservation Reserve Enhancement Program (CREP) is another state/federal program intended to improve not only wetlands, but also other riparian habitats in North Carolina. The program is focused on impaired water bodies in the Chowan, Neuse, and Tar-Pamlico river basins, and the Jordan Lake area (all Nutrient Sensitive Waters). The program can pay up to $50,000 per person, per fiscal year to replace marginal agricultural land with forested riparian buffers, grassed filter strips or wetlands. For the enrollment of 100,000 acres in North Carolina, federal and state obligations over a 15-year period are approximately $275 and $54 million, respectively (<http://www.fsa.usda.gov/crpstorpt/CREP/default .htm> , April 2003). During 1999-2003, 19,081 acres were enrolled in this program in North Carolina (calculated from USDA website, April 2003). However, the proportion of this acreage in wetland restoration or creation was not reported.[12]

In addition to the programs discussed above, other state programs involved in the restoration of wetlands include DWQ's 319 Program, Clean Water Management Trust Fund, and the Division of Water Resources' Grant Program (WRP 2002).[13]

Existing management measures

Legislation and regulatory programs

Alteration or destruction of wetlands is currently regulated by federal and state agencies. Numerous federal regulations and incentives affecting wetlands were included in the River and Harbors Act of 1899; the Clean Water Act of 1972 (and its amendments); the Food Security Act of 1985; the Food, Agriculture, Conservation, and Trade Act of 1990; the Emergency Wetlands Resources Act of 1986; and the Coastal Zone Management Act of 1972 (Bales and Newcomb 1996).

The River and Harbors Act gives the COE the authority to regulate certain activities in navigable waters. These activities include some that can damage or destroy wetlands such as diking, deepening, filling, excavating, and placement of structures. Section 404 of the Clean Water Act requires that the COE regulate the discharge of dredge or fill material into wetland areas. Permit applications are reviewed by the U.S. Environmental Protection Agency (EPA) and U.S. Fish and Wildlife Service (FWS). The Corps

[11] See "Recent trends" subsection under "Land use and wetland conversion" below for more information.
[12] More information on the CREP program can be found on the USDA's website (<http://www.fsa.usda.gov/dafp/cepd/crpinfo.htm>).
[13] Information on these programs is provided on the WRP website (<http://h2o.enr.state. nc.us/wrp/index.htm>).

can deny the permit based on FWS or NMFS recommendation. States were given the authority to approve, apply conditions to, or deny 404 permits by Section 401 of the Clean Water Act. The authority is applied in North Carolina by DWQ with the 401 Water Quality Certification program.

While issuance or denial of Section 404 permits are the most widely used federal management tool protecting wetlands, most farming, ranching, and silviculture activities are exempt from such permits (Bales and Newcomb 1996). These exemptions were reduced by the "Swampbuster" provisions of the Food Security Act of 1985 and its amendments. "Swampbuster" provisions discourage (through financial disincentives) the draining, filling, or other alterations of wetlands for agricultural use. However, there are exemptions from the disincentives if the farmer agrees to restore the altered wetland or some other wetland area converted to agriculture. Cutover wetlands impacts between 1988 and 1994 are likely the result of silviculture operations.

There are also section 404 and 401 general permits issued for projects causing minimal individual and cumulative environmental impacts. These permits are important because the activities they cover do not require wetland restoration. The most frequently used, but no longer issued, 404 general permit is Nationwide Permit 26, which applied to wetland fills less than 10 acres in size. This permit had the following general conditions: (1) the wetland must be located adjacent to a stream and above headwaters, or (2) the wetland must be isolated (equivalent to flat/depressional hydrogeomorphic class). Nationwide Permit 26 probably contributed primarily to loss of flat/depressional wetlands noted earlier in the Status and Trends section. Some other activities covered under federal general permits include:

- Fish and wildlife harvesting,
- Survey activities,
- Minor road crossings,
- Modifications of existing marinas,
- Maintenance dredging of existing basins,
- Boat ramps with no discharge to wetlands, and
- Cleanup of hazardous and toxic waste.

The Emergency Wetlands Resources Act of 1986 required states to address wetland protection in their Comprehensive Outdoor Recreation Plans in order to qualify for federal funding. Other wetland protection incentives were provided by the Coastal Zone Management Act, which required coastal states to adopt coastal zone management programs in order to be eligible for federal funding and technical assistance. As a result, the Coastal Resources Commission (CRC) was subsequently established in North Carolina. The DCM was later established as the operational arm of the CRC. Rules promulgated by the CRC apply to North Carolina's 20 coastal counties.

Within coastal counties, the CRC forbids projects that can violate water quality standards of estuarine resources, including coastal wetlands [CRC rule 15A NCAC 07H .0207]. The CRC rules also state that activities directly impacting wetlands shall not have significant adverse impacts. The CRC prohibits disposal of fill in coastal wetlands and dredging activities in all but the most narrow fringing wetlands [CRC rule 15A NCAC 07H .0208 (b) (1) (A, C)]. Furthermore, CRC rules require that bulkheads and riprap to be constructed landward of coastal wetland areas (Clark 2002). However, CRC and EMC rules allow bulkhead backfilling of small, freshwater wetlands landward of coastal wetlands following the size threshold criteria for permitting wetland impacts[14], resulting in a cumulative loss of wetlands that might provide for marsh migration with sea level rise. *To minimize these losses, all but the most miniscule of*

[14] Projects impacting less than 1/3 acre of wetland within 50 feet of the high water line are exempt from 401 water quality certifications, as well as projects impacting less than 1 acre within 150 feet of the high water line [EMC rule 15A NCAC 02H .0506 (c)(2)]. There is no minimum area criteria for mitigation when dealing with designated unique wetlands [EMC rule 15A NCAC 02H .0506(e)]. However, unique wetlands will likely not be designated on private lands without the approval of the land owner.

wetland impacts should be subject to permitting.

Encouraged by the progress of wetland regulations, "No Net Loss" policies were developed by the federal government in the late 1980s (Wiebe and Heimlich 1995). But despite their achievements, wetland regulations are still considered by the public a "taking" of property that should be discontinued or the landowner financially compensated. The central problem of wetland protection remains how to protect wetlands for public benefit when the majority of converted or remaining wetlands are privately owned. These factors have led to increasing reliance on land acquisition and direct incentives for protecting remaining wetlands. Increasing public awareness of wetlands benefits (i.e., reducing flood levels, velocities, and damage) encourages greater acceptance of wetland regulations, as well as voluntary actions.

State and federal regulatory designations

Several state regulatory designations provide additional protection of wetlands, such as area designations estuarine Areas of Environmental Concern [CRC rule 15A NCAC 07H .0205-207]; Nutrient Sensitive Waters [EMC rule 15A NCAC 02B .0101(e)(3)]; Primary Nursery Areas [MFC rule 15A NCAC 03N .0102(a)]; Shellfishing Waters [EMC rule 15A NCAC 02B .0101(d)(3)]; High Quality Waters [EMC rule 15A NCAC 02B .0101(e)(5)]; and Outstanding Resource Waters [EMC rule 15A NCAC 02B .0101(e)(4)].

The CRC-designated Estuarine Shoreline Area of Environmental Concern (AECs) extends landward 75 feet from the high water mark along estuarine shorelines upstream to the line separating Coastal and Inland Fishing Waters (Figure 2.7 in Chapter 2). The Estuarine Shoreline AEC increases to 575 feet along shorelines of EMC-designated Outstanding Resource Waters. Any development planned within this area must obtain a Coastal Area Management Act (CAMA) permit. Hard surfaces, such as buildings, paved parking lots and roads, must cover no more than 30% (25% along ORWs) of the project area within the Area of Environmental Concern, unless the development incorporates an innovative design that provides stormwater protection equal to or exceeding the protection of the 30% limitation. However, certain activities (i.e., agriculture and silviculture) not involving excavation or filling of coastal wetlands are exempt from a CAMA permit. The Coastal Shoreline AEC, which includes estuarine and public trust shorelines to the upstream extent of navigable waters, also includes a 30-foot buffer from high tide elevation in which only water-dependent uses are allowed. However, the vegetation in this buffer does not have to be natural, and it can be mowed. There are exemptions allowing non-water dependent structures within 30 feet of the high water mark. For example, the full buffer is not required if it would preclude the placement of residential structures on a lot, parcel, or tract that was platted before June 1, 1999 (if certain criteria are met) [CRC rule 15A NCAC 7H .0209 (e)(1)]. There are also exemptions for lots platted before June 1, 1999 or surrounded by existing development [CRC rule 15A NCAC 07H .0209 (e)(2)(A)].

Along Nutrient Sensitive Waters in the Tar-Pamlico and Neuse river basins, the EMC has established a buffer width of 50 feet directly adjacent to intermittent streams, perennial streams, lakes, ponds, and estuaries, excluding wetlands [EMC rule 15A NCAC 02B .0233 (3)]. The first 30 feet of the buffer (Zone 1) must be virtually undisturbed natural vegetation. However, within the 20 CAMA counties, Zone 1 is measured from the landward edge of coastal wetlands [EMC rule 15A NCAC 02B .0233 (4)(a)(iii)]. The zone of undisturbed natural vegetation could therefore include some freshwater wetlands not covered under CRC rules. The second 20 feet of the buffer (Zone 2) can be mowed grass and/or harvestable trees. While the buffer rules for Nutrient Sensitive Waters provide more protection for wetlands than CRC buffer rules, there are many exemptions [EMC rule 15A NCAC 02B .0233 (6)]. Most of the exemptions (over 35 in all) are for infrastructure associated with development (e.g., utility lines, drainage ditches, roads/bridges).

Waters designated as PNAs by the MFC are given additional consideration of impacts by DCM prior to

issuing development permits. Only maintenance dredging is allowed, and only within existing basins and channels. There are no other special requirements on water-dependent, development-related activities in wetlands surrounding PNAs (i.e., bulkheads, piers). However, all designated PNAs and SA waters are classified HQW and receive additional protection from discharge and development under EMC and CRC rules. Rules dealing with approved Shellfishing Waters protect wetlands by prohibiting new marina construction that could result in loss of some fringing wetlands and increased boat traffic and associated impacts [CRC rule 15A NCAC 07H .0208 (b) (5) (E)].

All coastal areas classified as Outstanding Resource Waters also have significant wetland coverage. Outstanding Resource Waters and their more stringent regulations [EMC rule 15A NCAC 02B .0225 (e)] encompass approximately 6% of the riparian wetland habitat in coastal North Carolina, the majority of which is salt/brackish marsh and riverine swamp forest. Those areas also cover 2% of non-riparian wetlands. There is also a larger Area of Environmental Concern (extending 575 feet from mean high water) adjacent to ORW waters, within which there is a built-upon area limit of 25% [CRC rule 15A NCAC 07H .209 (g)]. The limit on impervious surfaces could help prevent loss of wetlands within the AEC. *The effectiveness of ORW-related rules in protecting wetlands and other habitats should be examined and changed as necessary. Appropriate management strategies should be developed by the EMC, MFC and CRC to protect wetland areas designated as Strategic Habitat Areas by the MFC.*

The federal government protects wetlands by designating them Essential Fish Habitat (EFH). The designation of EFH for coastal wetlands means several things. First, the regional fishery management councils must identify measures to conserve, restore, or enhance Essential Fish Habitat. They must also recommend actions that will minimize the adverse effects of fishing on habitat. Most recommendations target federal agencies (i.e., Corps of Engineers or Environmental Protection Agency) whose projects may affect fish habitat. Basically, any state or federal activity that could harm habitat for federally managed fish stocks is subject to review by NMFS (NOAA Fisheries). Federally managed fish stocks include those occurring in federal waters as either permanent residents (i.e., tuna, sharks) or migratory transients (i.e., panaeid shrimp, red drum). Coastal wetlands are designated EFH for red drum and shrimp. Areas of EFH requiring the most protection are termed Habitat Areas of Particular Concern (for more information see Chapter 8).

Land ownership and management

In addition to regulatory designations, wetlands also receive protection by virtue of ownership and management. Protected lands are owned and managed by federal, state, county, and municipal governments, as well as conservation organizations, other nonprofit organizations and land trust properties. These protected lands cover 217,289 ac of riparian wetlands and 434,746 ac of non-riparian wetlands, representing approximately 16 and 26% of all riparian and non-riparian wetlands, respectively, in coastal North Carolina.[15] Based on the amount of 1994 wetlands within protected areas, 74% of wetlands are not protected by land ownership, although this amount does not account for regulatory restrictions and area designations on lands not managed for conservation. It also does not include lands with restoration cost-share agreements in the Wetland Reserve Program.

Within areas protected by conservation ownership and management, some wetlands types are more represented than others. Of the riparian wetland types, estuarine shrub/scrub, salt/brackish marsh, and estuarine forests are the most protected (28-52%; see Table 5.7). The riparian freshwater wetlands are relatively less protected (7-28%). Among hydrogeomorphic categories, headwater wetlands receive the least protection (6%). Most headwater wetlands are outside of estuarine shoreline AECs, and thus are not protected by CRC use standards. Projects impacting these small wetlands may often require only a

[15] This information was obtained by overlaying DCM wetlands data with "Land Managed for Conservation" coverage from BasinPro3 (software developed by the North Carolina Center for Geographic Information and Analysis).

Table 5.7. The amount and percentage of each wetlands type in eastern North Carolina within protected lands. Only undisturbed wetlands indicated on DCM GIS mapping of the Coastal Plains are included. *(Source: CGIA's BasinPro3 coverage, "Land Managed for Conservation")*

Wetland class	Wetland type	Protected (ac)	Total (ac)	% Protected
Riparian	Salt/Brackish Marsh	74,038	198,168	37.36
	Estuarine Shrub/Scrub	14,417	27,874	51.72
	Estuarine Forest	274	965	28.38
	Freshwater Marsh	9,091	32,803	27.71
	Bottomland Hardwood	16,301	227,582	7.16
	Riverine Swamp Forest	101,400	829,681	12.22
	Headwater Swamp	1,769	31,159	5.68
	TOTAL RIPARIAN	*217,289*	*1,348,232*	*16.12*
Non-riparian	Pocosin	299,225	507,117	59.01
	Maritime Swamp Forest	1,666	3,438	48.46
	Non-riverine Swamp Forest	101,154	215,305	46.98
	Pine Flat	74,912	296,591	25.26
	Hardwood Flat	15,041	165,077	9.11
	Managed Pineland	58,943	954,336	6.18
	TOTAL NON-RIPARIAN	*550,941*	*2,141,864*	*25.72*

general permit and no mitigation, or they may be exempt from a permit due to small size. Although there are no accurate records on the type of wetlands impacted by 401 Water Quality Certifications, headwater wetlands are believed to be one of the most heavily impacted wetland types (J. Dorney, DWQ, pers. com., 2003). *Due to the relative threat to, and ecological importance of, headwater wetlands, they should receive higher priority in wetland preservation/restoration efforts.*[16]

Statewide Wetland and Streams Management Strategy

In 1997, DENR received a grant from the EPA to develop a comprehensive, statewide plan to improve and simplify North Carolina's wetland and stream protection policies. The EPA provides financial, technical, and planning assistance to states interested in developing statewide wetland conservation plans. The EPA strongly supports development of statewide wetland conservation plans because these plans give states a framework to protect, restore, and create wetlands in an effective and efficient manner.

The objective of this strategy was to identify opportunities to make wetland, stream, and riparian buffer protection programs and conservation approaches work more efficiently and effectively in North Carolina. In 1999, a stakeholder Advisory Committee was convened to develop the strategy. The major stakeholder groups represented on the Advisory Committee include: agriculture, forestry, environmental groups, academics, industry, development, private consulting, local government, the COE, EPA, the Natural Resources Conservation Service, and North Carolina departments of Environment and Natural Resources, Transportation, Agriculture, and Commerce. Through a series of both private and public meetings, the committee identified eight priority issues that were further investigated by a smaller Technical Work Group in May 2000. These priority issues have been published in the Statewide Wetland and Stream Management Strategy (DWQ 2003) and are shown below:

- Unique wetlands – Examine the regulatory authority of the EMC and DWQ for unique wetlands, develop policy interpretations for definitions, and develop a list of candidate sites or a process to

[16] Wetland acquisition and conservation programs are listed in Appendix J.

determine potential sites.

- Wetland and stream mitigation – Develop flexible wetland and stream mitigation options.
- Local government roles – Examine the involvement of local governments in wetland management/protection and develop potential mechanisms to encourage involvement.
- Wetland preservation – Inventory existing wetland preservation activities in North Carolina, develop wetland preservation goals, and examine mechanisms to encourage involvement.
- Wetland mapping – Examine existing and planned wetland mapping efforts, determine need for additional and improved mapping, explore mechanisms to carry out new mapping efforts, and examine the role of Geographic Information Systems in wetland and stream management.
- Environmental education – Examine existing wetland and stream education programs and activities, determine need for additional education opportunities, and recommend new and improved education activities.
- Regulatory structure and process – Examine the 401 Water Quality Certification Program's strengths and weaknesses, develop options to address weaknesses, and develop options for clarification.

Net loss

During 1999-2002, 651.90 ac of wetlands were created or restored in coastal river basins. Over that same time period, there have been 549.79 acres of permitted wetlands impacts (Figure 5.4) and an estimated 2,406 acres of coastal wetland lost to erosion (802 ac/yr x 3 yr). So the rate of wetland creation/restoration would appear to surpass the rate of loss from direct human causes. However, the total permitted impacts do not include the cumulative impact of very small losses that go untracked by permit authorities. *A study should be conducted to determine the cumulative impact of small wetland losses on the distribution and abundance of wetland types in a watershed. The cumulative loss could then be related to the nature and extent of development pressure in the watershed in order to formulate a model predicting untracked losses in other watersheds. But regardless of empirical evidence, small cumulative impacts may have a negative impact on fish habitat. Rules should be modified to reduce net loss of riparian wetlands from small cumulative dredge and fill projects (i.e., lower size threshold of wetland impacts that require permit or mitigation).*

5.4. THREATS AND MANAGEMENT NEEDS

Physical threats

Because physical alterations primarily impact wetlands, land use changes associated with population growth are the primary cause of wetland habitat loss today (Dahl 2000). Large-scale draining and ditching are prevalent agricultural impacts, whereas deforestation and fill are associated with silviculture activities and upland development. Shoreline stabilization is primarily a coastal phenomenon. Dredging access channels for upland boat basins can destroy wetlands, while bulkheading can increase erosion along adjacent wetland shorelines. The direct effects of land use changes and hydrologic modifications on riparian wetlands are discussed in the following sections.

Land use and wetland alteration

Historical conversions

The major cause of wetland loss and degradation has been conversion to agriculture, silviculture and upland development (including road construction). In the late 1800s and early 1900s, the greatest losses resulted from ditching and draining for agriculture. Several large agricultural drainage projects occurred during that period (Heath 1975), resulting in an estimated 1 million miles of drainage ditches and canals throughout the Coastal Plains of North Carolina (Wilson 1962). Much of the land around the Albemarle-Pamlico estuary was drained and must remain drained to accommodate existing agriculture and forestry. About one-third of the loss of wetlands has occurred since 1950 (Bales and Newcomb 1996). After 1950,

conversion to managed forest and agriculture accounted for 53% and 42%, respectively, of wetland losses (Bales and Newcomb 1996). Many of the roads on the Albemarle-Pamlico Peninsula were constructed on top of spoil piles between canals to prevent flooding on the roads. Ditching of wetlands or uplands is also common in other areas of the coast for flood control and drainage. In many urbanized coastal areas, ditches and swales are typically constructed along neighborhood streets. The ditches often connect and drain into headwaters, which alters the natural hydrology of downstream systems (Pate and Jones 1981).

Many government policies restrict ditching and draining of wetlands. Drainage of low-lying farmland funded by the USDA's Natural Resources Conservation Service (NRCS) and mosquito ditching are no longer common practices. Swampbuster provisions of the 1985 Farm Bill discouraged the practice of draining wetlands for conversion to cropland. However, drainage channels for croplands are still maintained by drainage districts (DEHNR 1995). Except for a short period from 1998 to 2000, there have been no new large-scale wetland drainage projects since the mid-1970s (Chicod Creek, Pitt and Beaufort counties, Tar-Pamlico MU). Prior to 1998, ditching/draining of wetlands was regulated by the COE. At that time, ditching required a federal 404 permit with a DWQ 401 certification, to ensure that water quality standards were not violated. When the federal court overturned the federal Tulloch rule in June 1998, the COE lost authority to issue permits for wetland ditching unless spoil was placed on adjacent wetlands. As a result, thousands of acres of wetlands were drained, primarily in Brunswick, New Hanover, and Pender counties (J. Steenhuis, DWQ, pers. com., 2002). Approximately 9,500 acres of wetlands were impacted in Brunswick County alone (DWQ 1999), and a total of approximately 11,580 acres of wetlands were impacted in the Coastal Plain. These losses are in addition to 401 Water Quality certification records. In Brunswick, New Hanover, Pender, and Onslow counties, 24% of the ditching was reported as forestry-related, 6% as agriculture-related, and 70% was done for development or other purposes (J. Steenhuis, DWQ, pers. com., 2002).

In 1999, the State of North Carolina determined that wetlands ditching and draining activities fall under its authority, constituting an illegal activity if proper approval is not obtained. In 1999, EMC adopted a wetland draining policy to ensure that required wetland conditions are maintained (<http://h2o.enr.state.nc.us/ncwetlands/ditch.html>, 1999). In addition, inspections were made of previously ditched wetlands to determine if the ditching was conducted in a manner that violated wetland standards. Where violations occurred, property owners were required to restore the natural hydrology through the filling of the ditches. Approximately 50% of the ditched wetlands have been restored, 22% are likely not to be restored, and the status of the remainder is undetermined (J. Steenhuis, DWQ, pers. com., 2002). Many of the remaining ditches, although not appearing to be violating water quality standards, continue to transport stormwater into coastal waters. *Additional monitoring is needed to better assess impacts where extensive areas of wetlands were drained. More DWQ staff are needed to inspect for compliance with water quality standards, including wetland draining.*

In addition to conversion to upland development, agriculture, and silviculture, many wetlands were also converted to deepwater habitat. Based on national trends during the mid-1970s, the major source of coastal wetland loss was conversion to deep water habitat (e.g., boat basins, navigation channels), followed by upland development (Hefner and Brown 1985). The CRC currently prohibits dredging through all but the most narrow fringing marshes [CRC rule 15A NCAC 07H .0208 (b)(1)(A)]. Many acres of wetlands were dredged for the Intracoastal Waterway (1930s), boat basins, and connecting channels before dredge and fill and CRC rules were implemented. The primary dredging activities still occurring within North Carolina's coastal waters are maintenance or improvement dredging of existing navigation channels (DEHNR 1995). These projects have relatively little affect on existing wetlands. However, small non-coastal wetlands, contiguous to coastal wetlands, are still lost to the backfilling of bulkheads.

Forestry operations do not require a 401 or CAMA permit when the hydrology of the wetland area is maintained. A violation of the Clean Water Act occurs if any wetland area benefiting water quality was

converted to uplands, without a permit. The forestry exemption can be an issue when there is dispute concerning how forestry operations alter different wetlands types. Altering some wetland types would have a negative impact on downstream water quality, while altering other types would have little affect on water quality. If a forestry operation is allowed the exemption to alter a wetland benefiting water quality, and later sold the property to someone claiming the site had become an upland, the development is exempt from water quality permits and mitigation requirements. The Corps of Engineers and EPA signed a Memorandum of Agreement describing the types of wetlands in which mechanical forestry site preparation activities required a permit (<http://www.epa.gov/owow/wetlands/guidance/silv2.html>, June 2004). The resulting list included all riparian wetlands. Therefore, no mechanical forestry operation can legally alter a riparian wetland without obtaining a 404 permit or 401 Water Quality certification.

In a recent court case related to the drainage activities during 1998-2000, a development company tried to claim the forestry exemption when it ditched and drained over 200 acres of wetlands in Onslow county (N.C. Shellfish Growers Association and NCCF vs. Holly Ridge Associates; The U.S. District Court for the Eastern District of North Carolina, Eastern Division, No. 02cv0053). The judge said the ditches and the site itself were all "point sources" of stormwater and sediment pollution, and therefore required discharge permits under the Act – even if the activities were for forestry purposes. In a related state case, an administrative judge ruled there was no credible evidence that the ditching and drainage were for the purpose of forestry. Holly Ridge Associates was found in violation of the Clean Water Act for not obtaining a CAMA permit, a 401 Water Quality Certification, and an NPDES discharge permit. These two cases should prevent other land development and forestry companies from ditching or draining riparian wetlands without obtaining water quality and discharge permits. *Any ditching activity resulting in nonpoint source pollution in North Carolina's rivers and sounds should require an NPDES permit. The EMC's constraints on discharges in SA waters could then be extended to drainage projects, in addition to wastewater treatment plants.*

The cutover wetland acreage from 1988 to 1994, noted in the Status and Trends section (above), was likely the result of silviculture operations. The alterations occurred in both forested riparian and non-riparian wetlands (17,513 and 40,316 acres, respectively; Tables 5.4 and 5.5). The majority of alterations were to non-riparian forested wetlands. Using the rate of cutover impacts from 1988 to 1994, approximately 21,000 more acres of riverine forested wetland may have been impacted from 1994 to 2003. As long as wetland hydrology is maintained, this is a relatively minor issue. If upland development replaces these cutover woodlands, there could have been a violation of the Clean Water Act.

Recent trends

To examine recent trends in wetland conversion, an analysis of wetland impact sources was performed on approximately 6% of the total number of 401 certification records from the DWQ database, covering a time period from 1997 to 2003 (1,213 of 18,700 total records). The data were filtered to include only those records within CHPP management units (based on geographic coordinates) having a date, project type (excluding wetland restoration/creation), and area impacted (DWQ, unpub. data). The analysis is unbiased toward certain impact types assuming the data represent a random subsample. Impact source categories for analysis of 401 permit records:

- *Water control* includes the construction of impoundments, reservoirs, ditches, canals, water intakes, storm drains, stormwater ponds, and other activities designed to alter water flows. Some water control projects are related to transportation.
- *Upland development* includes isolated ponds, residential lots, commercial facilities, utility cables/pipelines, wastewater treatment plants, schools, churches, and other activities converting wetland habitat to uplands or supporting upland development.
- *Mining* includes quarry and sand pit construction or expansion, and other mining sources.
- *Agriculture/aquaculture* activities include irrigation ponds, farm construction, clearing land for animal operations, fish hatcheries, fish farms, spray fields, and similar activities that disturb wetland hydrology.

- *Transportation* includes construction of roads, highways, bridges, and culverts.
- *Water-dependent development* includes piers, docks, marinas, navigation channels, boat ramps, shoreline stabilization structures, channel relocation, and similar activities and structures associated with waterways.

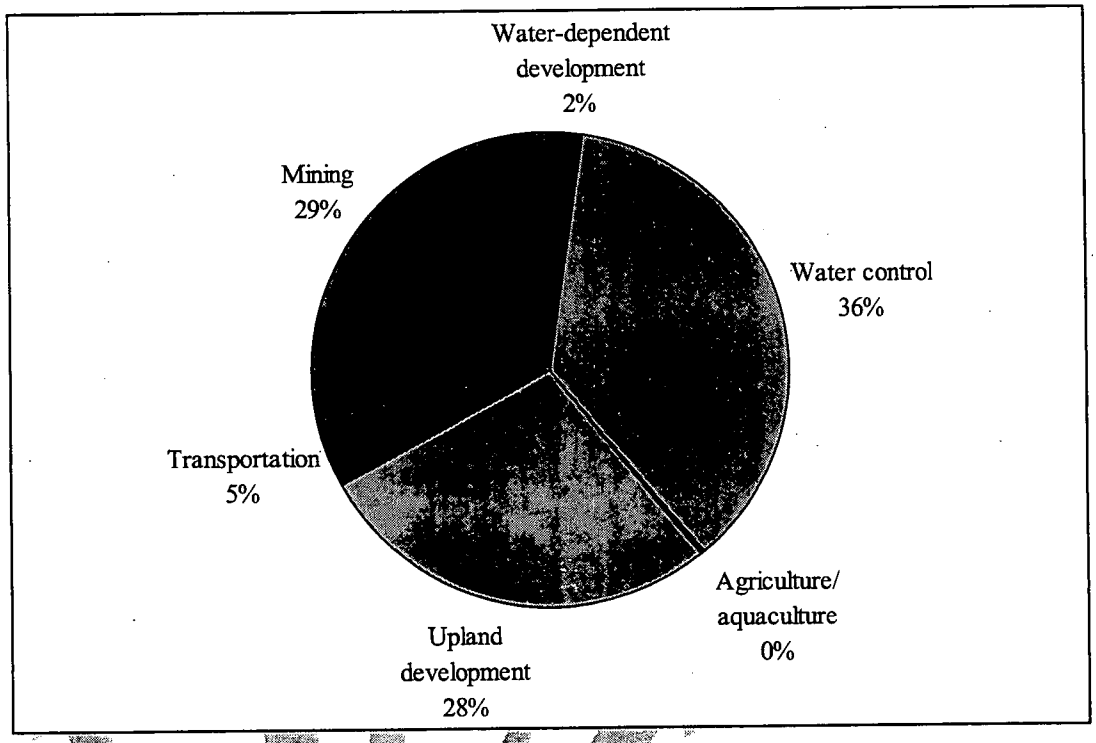

Figure 5.6. Sources of wetland impact in eastern North Carolina. *[Source: subset of DWQ Section 401 certification records (1997-2003), with location coordinates within CHPP management units.]*

The most recent trends (1997-2003) in wetland loss show water control projects as the major source of wetland impacts (36% of impacted acres) (Figure 5.6), followed by mining (29%) and upland development (28%). The vast majority of mining impacts occurred during a single project in 1997 when PCS Phosphate was issued a permit to destroy 1,268 acres of wetlands in Beaufort County (The U.S. District Court for the Eastern District of North Carolina, Eastern Division, No. 02cv0053). Activities least impacting wetlands included agriculture/aquaculture (<1%), transportation (5%), and water-dependent development (2%) (Figure 5.6).

North Carolina Department of Transportation projects accounted for 23% of permitted wetlands impacts during 1997-2003, based on 11% of 18,700 permit records (DWQ, unpub. data). The DOT spends more than $80 million each year mitigating the impact of bridges and other road crossings on wetlands (*Water Resources Research Institute News*, March/April 2003), causing considerable delays in road construction. In recognition of the problems resulting from these delays, DOT, DENR, and COE have developed a program to improve efficiency and provide sufficient mitigation, the Ecosystem Enhancement Program (EEP). The new program, established through an agreement among agencies, brings together mitigation staff from the WRP and DOT under DENR's umbrella. The EEP will estimate potential wetland impacts very early in the roadway planning process (*Water Resources Research Institute News*, March/April 2003). Prior to mitigation, potential impacts will be evaluated in a watershed context, having targeted priority areas for mitigation efforts. Functional assessment will be conducted prior to the permitting

process for the transportation project. Priorities will be consistent with DWQ basinwide planning reports, Coastal Habitat Protection Plans, and Wetland Restoration Plans. Once in place, mitigation projects will be monitored to determine their effectiveness in replicating wetland functions. *Eventually, the EEP should include mitigation planning for upland development and other approaches to habitat enhancement, restoration, and preservation..*

Shoreline stabilization

Shoreline stabilization is modification of the natural shoreline to prevent or reduce landward migration of the shoreline. The purpose of shoreline stabilization is protection of man-made structures and property, including natural features. As shoreline development increases in conjunction with rising sea level, waterfront structures will be threatened more often and property owners will likely have greater interest to protect their property. Shoreline stabilization in estuarine areas generally utilizes hard stabilization techniques. Bulkheads are the primary hard stabilization structure.

Construction of seawalls and jetties are primarily oceanfront practices; they are discussed in the Soft Bottom and Water Column chapters (Chapter 2 and 6). Soft stabilization includes beach bulldozing or beach nourishment, which are also discussed in the Soft bottom chapter (Chapter 6). This section will discuss the extent of estuarine shoreline stabilization that has already occurred in North Carolina, impacts of this activity on riparian wetlands, and management needs to reduce or minimize such impacts.

Physical and biological effects

Hard stabilization techniques have fairly severe impacts on coastal habitat, including accelerated erosion, loss of shallow intertidal bottom, loss of fringing marshes, increased scouring and turbidity in nearshore waters, and obstruction to fish migration where structures are perpendicular to the shoreline (Walton and Sensabaugh 1979; Pilkey and Wright 1989; Pilkey et al. 1998; Peterson et al. 2000). Two managed fishery species strongly linked to fringing marsh are penaeid shrimp and red drum (SAFMC 1998). Other important estuarine-dependent fish species that utilize wetlands during larval and juvenile life stages include gag, snapper, Spanish mackerel, striped bass, and river herring (SAFMC 1998). Degradation and loss of wetland habitat from shoreline hardening impacts these species, as well as many others.

Bulkheads impact wetlands in several ways. During construction, heavy equipment and backfilling may destroy vegetation above the high water line (wetland and transitional wetland plants), where bulkhead construction is allowed. Along the CRC's Estuarine Shoreline AEC, a 30 foot buffer above the high water line is established in which only water-dependent uses are allowed [CRC rule 15A NCAC .07H .0209] provides exceptions to the buffer requirement). Rather than allowing natural vegetation to recolonize the area, property owners generally plant landscape scrubs and lawn grasses. These plants are not as effective at deterring erosion or reducing and cleansing stormwater as natural vegetation. Increased nutrients and toxins from fertilizers and pesticides used on the lawn enter the water with the runoff (Watts 1987). Bulkheads also prevent shoreward migration of fringing wetlands as sea level rises, resulting in eventual drowning and loss of existing wetlands (Titus 1988).

McDougal et al. (1987) found that nearshore wave impact increases as the horizontal length of the structure increases. Therefore, the cumulative effect of multiple, contiguous bulkheads has a greater impact on adjacent natural shoreline habitat than the effect of individual structures that are spatially distinct. Scouring action at the toe of bulkheads results in deepening of the adjacent water, thus reducing or eliminating intertidal habitat. Shallow water habitat is also reduced because the bulkhead structure prevents transport of sediment to other areas (Riggs 2001). The added turbulence at the base of bulkheads prevents vegetation from reestablishing after construction (Knutson 1977). Garbisch et al. (1973) showed that marsh vegetation waterward of bulkheads experienced a 63% mortality post-construction due to stress from increased turbulence and scour. This loss of habitat reduces benthic food resources for juvenile, anadromous, estuarine-dependent, and surf fish, as well as shore birds, which are highly

dependent on shallow intertidal habitat for feeding (Peterson et al. 2000; Byrne 1995; DMF 2000). The deepening also increases the feeding efficiency of large piscivorous fish on small and juvenile fish that occupy the shallow waters adjacent to the structure (Rozas 1987).

Several studies have documented lower relative abundance and diversity of invertebrates and juvenile fish adjacent to bulkheaded shorelines compared to unaltered marsh, beach, or forested wetland habitats:

- Peterson et al. (2000): On the Gulf coast, the most abundant species groups along unaltered marsh and beach shorelines (including habitat for penaeid shrimp, crabs, gobies, grass shrimp, drums species, and shad/herring species) were least abundant along bulkhead or rubble shorelines. In addition, diversity was lowest adjacent to bulkheads.
- Byrne (1995): In a Barnegat Bay lagoon, New Jersey, littoral fish and shrimp abundance was consistently and significantly lower at bulkheaded sites. The differences were attributed to lower levels of structural complexity, since SAV, macrophytic algae, snags, overhanging and submerged branches, and woody debris were absent from the bulkheaded sites, but present at the unaltered sites.
- Ellifrit et al. (1972): Fewer clams (*Venerupis japonica*) were present near bulkheaded areas compared to natural areas. The difference was attributed to less favorable conditions for settling and survival of clam larvae.
- Gilmore and Trent (1974): For all groups combined, benthic organisms were numerically and volumetrically less abundant in bulkheaded canals than in natural marshes. Crustaceans were over three times less abundant.
- Mock (1966): Brown and white shrimp abundance was 80% less in front of a bulkheaded shoreline compared to naturally vegetated shoreline. The difference was attributed to lower abundance of organic detritus and benthic macroinvertebrates, deeper water, and less intertidal vegetation.
- Bulkheads reduce or degrade spawning and nursery habitat for anadromous fish (SAFMC 1998; DMF 2000). Cumulative impacts of bulkheads have been specifically cited as a contributing factor to the decline of chinook salmon on the Pacific coast (Taylor 1999).
- O'Rear (1983) found that early larval river herring in the tributaries of the Chowan system were highly associated with the stream edge and waters with minimum flow. Shoreline hardening impacts the stream edge on which these larvae depend, and can accelerate flow, thereby making areas adjacent to bulkheads less suitable for use by larval or juvenile anadromous fish.

Most of the studies on the biological impact of bulkheads on fish and their habitat were not conducted in North Carolina. However, a recent study by the WRC (Water and Thomas 2001) examined impacts of bulkheads and other hardened shorelines (i.e., rock revetments) on fish utilization in northeastern North Carolina waters, particularly spawning success and juvenile recruitment of anadromous fish species. They found significantly lower abundance and species diversity of fish adjacent to bulkheads, compared to forested wetland shoreline and rip rap. The study also found higher abundances of juvenile fish along rip-rap and natural shoreline than along bulkheads, and a comparable number of quality size gamefish. The difference in juvenile abundance was attributed to both greater complexity of rip-rap and natural shoreline, and their location near shallower water. These results indicate a reduction in nursery function along bulkheaded shorelines.

Vertical hardened structures are also problematic for marine species that move between water and land during their life cycle. Along the estuarine shoreline, bulkheads are a physical barrier to animals such as the eastern mud turtle, yellow-bellied turtle, and northern diamondback terrapin (a species of "concern" in North Carolina) that live and feed in the marsh, but nest above the high tide line (Ernst and Barbour 1972).

Cumulative effects

North Carolina's policies and rules for estuarine erosion management allow landowners to protect their property from erosion, while attempting to minimize the impacts of erosion control structures. Past and current CRC rules have greatly reduced losses of wetlands and shallow bottom by restricting placement of vertical structures in or seaward of coastal wetlands, and restricting backfilling of the associated landward wetlands. Although currently used techniques may effectively protect waterfront property, immediate and long-term impacts to wetlands often occur, and alteration of sediment supply affects natural shoreline processes and wetland migration. In addition, bulkheads are sometimes permitted and constructed where an erosion problem is not evident. The DCM is working towards permitting stabilization methods only where an identifiable erosion problem occurs. *Better criteria to define an "erosion problem" and aid in proper utilization of erosion control structures are needed and should be developed by the DCM and CRC.*

While a single bulkhead may have little effect on adjacent habitat, the cumulative impact of multiple bulkheads along estuaries can result in significant habitat degradation. Between 1984 and 2000, DCM issued permits to bulkhead approximately 457 miles of shoreline (11.7% of the estimated 3,900 miles of estuarine shoreline). During this time period, the amount of bulkheading permitted annually along the coast has ranged from eight to 91 miles (Figure 5.7). These numbers must be considered with caution since there may be data entry errors. In addition, the CAMA permits include repairs, replacements, or projects that may not have been done or completed. Numbers appear to increase sharply from 1997 to 2000, probably due to the large number of repairs following a series of damaging hurricanes during 1996 – 1999, and strong economy in the mid-1990s. The highest number of bulkhead permits issued annually occurred in 1999. The total amount of bulkheading per county has ranged from less than one mile in Gates County to 109 miles in Beaufort County and 79 miles in Dare County (Figure 5.8). Beaufort, Dare, Carteret, and Currituck counties have the greatest total lengths of permitted bulkheads. In these counties, the percent of hardened shoreline along major waterbodies ranges from roughly 8% to 32%. Because of the limitations of the current database on bulkheading, and the potential impacts to habitat, particularly nursery areas, *there is a need to more accurately assess where and how much of the estuarine shoreline is hardened. With more accurate information, the level of impact to marine resources can be assessed.*

Draft

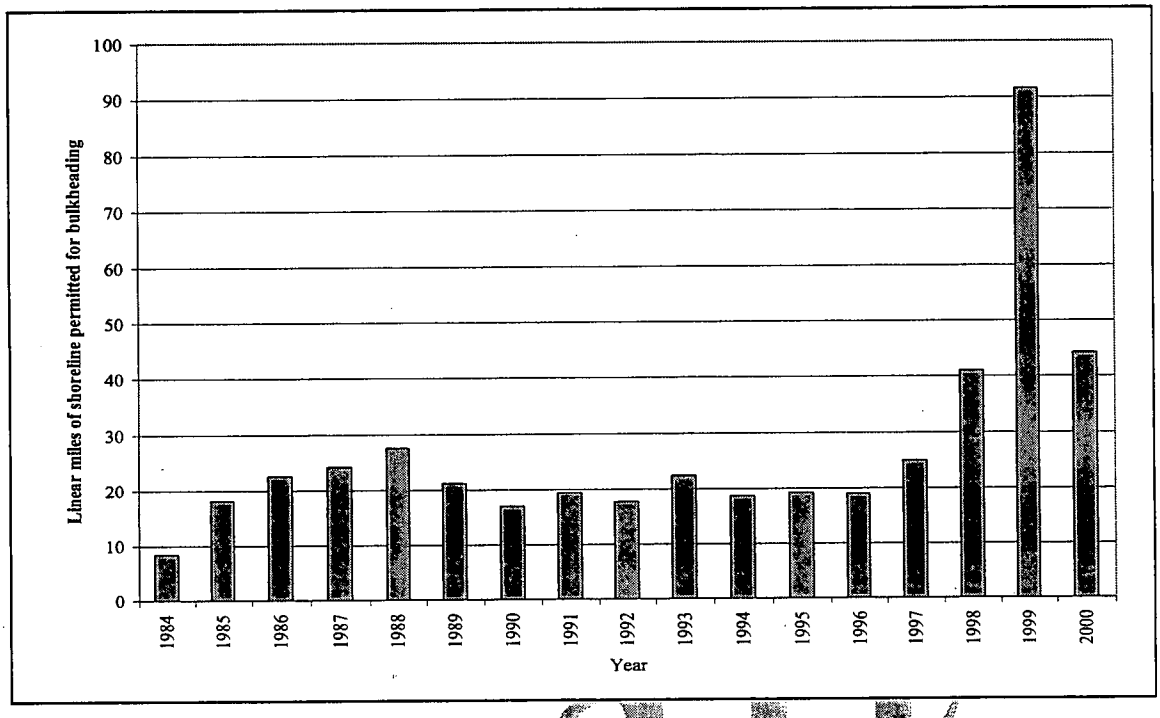

Figure 5.7. Linear miles of bulkheading permitted by year, 1986-2000. *(Source: DCM, unpub. data)*

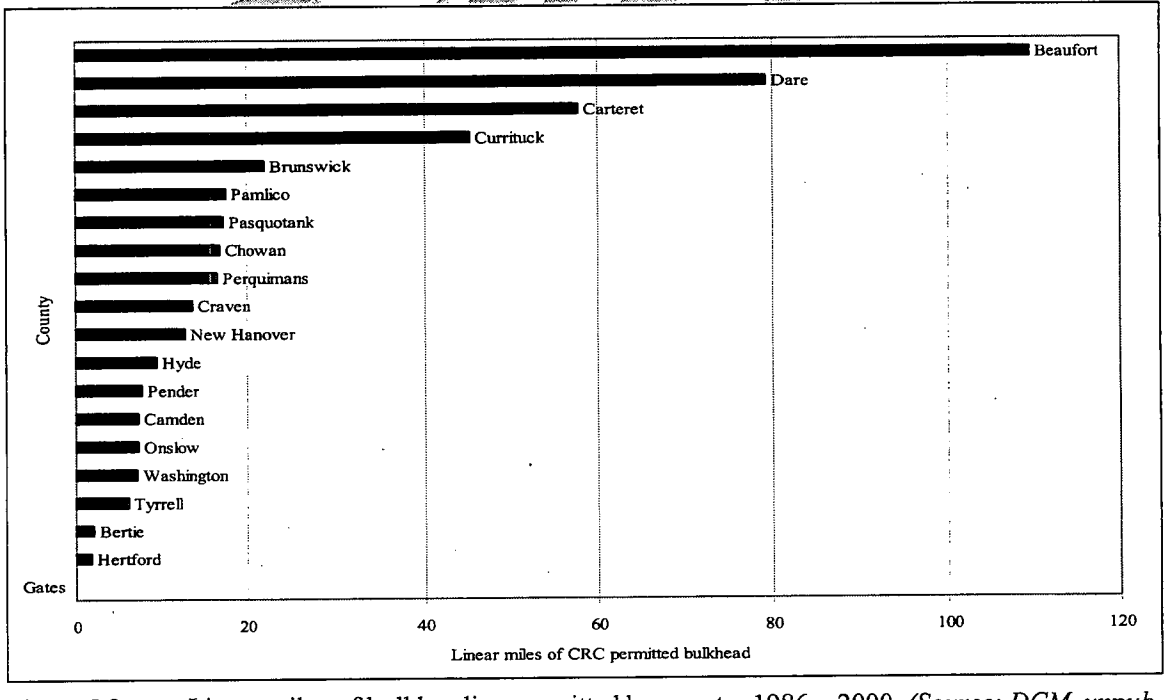

Figure 5.8. Linear miles of bulkheading permitted by county, 1986 – 2000. *(Source: DCM, unpub. data)*

A pilot study conducted by DMF along approximately seven miles of estuarine shoreline in the southern portion of the coast (Pages Creek and Intracoastal Waterway in New Hanover County) found that approximately 21% of the shoreline within the study area was hardened in 1984. By 2000, 37% of the

shoreline in the same area was hardened. The most affected area of shoreline was along the ICW, where boat wakes and greater fetch increase erosion problems; 54% of the area examined was hardened. However, even along a protected creek (Pages Creek) with a wide marsh fringe and little obvious erosion, 38% of the shoreline has been hardened. Along Yeopim Creek, a tributary of Albemarle Sound, approximately 1% of the shoreline was hardened in 2000. *The methodology used for assessing shoreline hardening (examination of aerial photographs) could be used for a larger portion of the coast to spatially delineate and quantify where and how much of the shoreline is hardened.*

Although CRC rules state that sloping riprap or vegetation, rather than vertical seawalls/bulkheads, should be used where possible [CRC rule 15A NCAC 07H .0200 (7)(E)], bulkheads continue to be constructed at a greater rate than alternative shoreline protective methods. Recognizing the extensive, and at times inappropriate, use of bulkheads in North Carolina's estuaries, DCM modified the permitting process in 2001, requiring a General Permit for bulkhead construction less than 500 linear ft (rather than an exemption) and a Major Permit for those greater than 500 linear ft. Also, in 2000, the Estuarine Shoreline Stabilization Subcommittee was established by the CRC to review the estuarine shoreline rule development process. The Subcommittee developed a set of principles and concepts to guide further development of any shoreline stabilization rule changes (Figure 5.9).

Draft

1) The State of North Carolina has the authority under CAMA and the Dredge and Fill Act to regulate placement and installation of shoreline stabilization measures.
2) Only property owners with demonstrable erosion problems* may be eligible to obtain a permit to stabilize the shoreline. * CRC will define "erosion problem".
3) Stabilization techniques should be appropriate for site and erosion forces present.
4) Measures with the least adverse environmental effects are preferred (General preference for soft structures).
5) The goals of establishing standards for estuarine and public trust shorelines are:
   a) To safeguard and perpetuate the natural productivity and biological, economic and esthetic values of natural ecological conditions of the estuarine system (Protection of Habitat and Water Quality).
   b) To Insure that the development or preservation of the land and water resources of the coastal area proceed in a manner consistent with the capability of the eland and water for development, use, and preservation based on ecological considerations (Appropriate Development For Site).
   c) To insure the orderly and balanced use and preservation of our coastal resources on behalf of the people of North Carolina and the nation (Protection of Public Trust and Private Property Rights).
6) CRC will create development standards for stabilization technique/measures.
   a) Soft Measures
      i) Grading and Planting
      ii) Wetland Planting
   b) Hard Measures
      i) Bulkheads
      ii) Groins and Jetties
      iii) Breakwaters
      iv) Sills
      v) Revetments
      vi) Wave-boards (wooden breakwaters)
   c) Combinations
7) Stabilization measures shall be located as far landward as feasible.
8) CRC will set standards for existing stabilization projects:
   a) Allowing for tying with existing stabilization projects and adjoining lots
   b) Allowing for hardened structures on constructed canals and basins
   c) Allowing in kind/in place repair
   d) Allowing for in kind/in place replacement
9) Allow for larger footprint for riprap for achieved desired slope (1: 1 ½).
10) CRC will attempt to keep criteria and standards simple to understand and implement.
11) CRC will gather public input on the above principles and provide guidance on the concepts prior to DCM developing draft rule text.

Draft

Figure 5.9. CRC concepts/principles for estuarine shoreline stabilization policy assessment and development (DCM 2002).

In addition, a science-based panel, the Estuarine Biological and Physical Processes Work Group, was formed by DCM to develop recommendations for shoreline stabilization rules that adequately take into account and reflect the dynamic nature of the estuarine system (DCM 2002). The approach the group took was to evaluate which erosion control methods would be effective on various shoreline types, considering the ecological functions of each shoreline type. Wetland shoreline categories included swamp forest and marsh shorelines, and sediment banks with a marsh or swamp forest fringe. Erosion control options included vegetative planting, beach fill, marsh toe revetment, rock sill, wood or rock breakwater, gabions, groins, riprap, and bulkheads. Non-vertical structures, such as rock sills, oyster reefs or marsh toe revetments, where suitable for erosion control, can have more habitat advantages than

vertical structures, since they provide three dimensional structure and areas of refuge for fish and invertebrates. A channel left between sills allows juvenile fish access to the inner marsh. However, even this structure can increase erosion on adjacent shorelines, albeit much less than on shorelines next to bulkheads. Marsh grass planting creates the least erosion along adjacent shorelines, but offers the least protection of property. Advantages and disadvantages of each effective erosion control method were discussed and the preferred methods that minimize impacts to the hydrological, biogeochemical, and ecological functions of each specific shoreline type were ranked. For example, adjacent to a high bluff with a sand fringe, a bulkhead structure may be preferred over a rip-rap rock structure. However, along a low-lying upland with a marsh fringe, a wood or rock structure on the waterward edge of the marsh would be preferred over a wood or rock structure on the upland edge of the marsh, and bulkheads would not be an appropriate option. This effort is still underway and needs review by the Estuarine Shoreline Stabilization Subcommittee once complete (DCM 2002).

The CRC should revise estuarine shoreline management rules using best available scientific information, including the recommendations from the Estuarine Shoreline Biological and Physical Processes Work Group to minimize impacts to natural shoreline and nearshore fish habitat functions. As part of the process of modifying shoreline management rules, accurate estuarine shoreline erosion rates are needed to aid in identifying "erosion problems," determining adequate shoreline setbacks, and determining appropriate erosion control methods where necessary. Wherever possible, sections of estuarine, non-vegetated shoreline with very little hard stabilization should remain unaltered to provide "new" sediment for shallow water habitats (Riggs 2001). Some consideration should also be given to the type of material used in rock structures because oysters more readily colonize oyster cultch material or limestone marl, than granite.

Impervious surfaces

The increase of impervious surface in coastal North Carolina causes loss and degradation of both riparian and non-riparian wetlands. Impervious surfaces affect wetlands indirectly by preventing infiltration into the soil and shallow groundwater tables, thus reducing discharge to certain groundwater-dependent wetlands (EPA 1993c). There can also be greater bank erosion and channel incision in riparian wetlands located near impervious surfaces and their associated drainage networks (EPA 1993a; EPA 1993c).[17]

Channelization and ditching

Channelization is the deepening and straightening of a natural stream or dredging of a new channel for the primary purpose of improving drainage of adjacent lands (UNC Sea Grant 1999). These activities can affect the slope, depth, width and roughness of the channel, thus changing the dynamic equilibrium of the stream (including associated wetlands). Channelized streams are deeper, more variable in flow, and less variable in depth than natural streams (Orth and White 1993). These differences affect primarily smaller species and life stages using wetlands and shallow stream margins, habitats that are reduced by channelization. In many channelized streams in the middle and lower Coastal Plain, storm flows are confined primarily to the main channel rather than passing through wetlands. This change greatly reduces the natural beneficial functions of wetlands to filter pollutants and regulate water flow between uplands and coastal waters. In addition, the riparian zone (including the natural woody vegetation along the sides of the stream) is often removed in the process of channelization (NRC 2002). Consequently, loading and movement of sediment and other nonpoint source pollutants are often greater in channelized streams than in natural streams, which can have negative effects on water quality and fish habitat (EPA 2001; White 1996). Channelization also increases channel cross-section and flow capacity, thus reducing the frequency of overbank flow events that allow fish access to the wetlands. The remaining wetlands exist with an altered hydrology; relying more on overland flow from upland areas and groundwater discharge, and/or overbank flow from unchannelized stream segments nearby.

[17] Refer to Chapter 2 for more information on impervious surfaces.

Although new channelization for flood control and drainage has greatly decreased, the existing alterations continue to alter flow and salinity patterns.[18] *Dechannelization of streams, restoration of wetland hydrology, use of alternative drainage techniques, and on-site BMPs are therefore needed to maintain and restore wetlands, flows and salinity patterns in downstream areas. In addition, increased funding and educational outreach to farmers and other landowners are needed for projects that restore natural stream and wetland functions.*

Dredging for navigation

Dredging impacts wetlands indirectly by limiting the amount of shallow water habitat available for colonization. The spoil from dredging can also be used to create shallow water habitat. At a number of sites, the COE has established wetlands as part of their management of dredge spoil islands; the spoil islands in Pamlico Sound west of Oregon Inlet are good examples. However, CRC rules generally require confining all dredging material to an upland area landward of regularly or irregularly flooded marsh [15A NCAC 07H .0208]. In recent years, cooperative interagency projects have resulted in some beneficial uses of dredge materials, such as creation of marsh and water bird nest sites.

Boating

The most detrimental effect of boating on wetlands is probably loss of vegetation from wave action. The actual impact of boat wakes on wetlands has not been quantified (SAFMC 1998; Riggs 2001). Erosion from boat traffic along the Intracoastal Waterway and elsewhere is readily observable and is likely responsible for substantial (or just localized) loss of fringing wetland habitat (Riggs 2001). The loss of fringing wetland can result in increased erosion of waterfront property along the Intracoastal Waterway. As the human population of coastal North Carolina increases, so will the impact of boater-induced wave turbulence. The number of registered boats in North Carolina increased by 26% from 1990 to 2000 (see Figure 4.3 in Chapter 4). *There is a need to amend WRC no wake zone authority to include consideration for erosion in strategic wetland areas.* Currently, the issue of human safety is the only issue driving the WRC's authority (habitat protection is not a consideration). *There should also be increased public awareness of the impact of boat wakes on wetland shorelines.*

Marinas, docks, and piers

Direct impacts to wetlands through marina construction are minimized since current CRC rules encourage marina construction in upland basins. Marinas, docks, and piers can impact wetlands indirectly by shading and associated boat traffic. Shading results in the loss of plant growth and vigor beneath the dock structures. A study in South Carolina compared stem densities of *Spartina* under docks with stem densities five meters away from docks (Sanger and Holland 2002). The results of the study indicated an average reduction in stem density of 71% under the docks. The study concluded that although shading of *Spartina* by docks reduces stem density, the total impact on wetland habitat was minor. It was estimated that by the year 2010, only 0.02 to 0.24% of the total salt marsh area in South Carolina would be affected by dock shading. However, local effects in areas with many docks could be significant.

The number of pier general permits issued in coastal North Carolina has risen from about 250 in 1990, to about 800 in 2002 (DCM, unpub. data; Figure 5.10). Additional numbers of large piers are also constructed every year throughout the coastal area. To minimize shading effects in North Carolina, CRC rules require a dock height of three feet above wetland substrate, and a pier width of no greater than six feet. As in South Carolina, the impact of dock and pier shading on wetland vegetation on a coastwide basis may be minor at present, but the impact will likely increase over time as more piers are constructed.

[18] See Chapter 2 section on channelization and ditching.

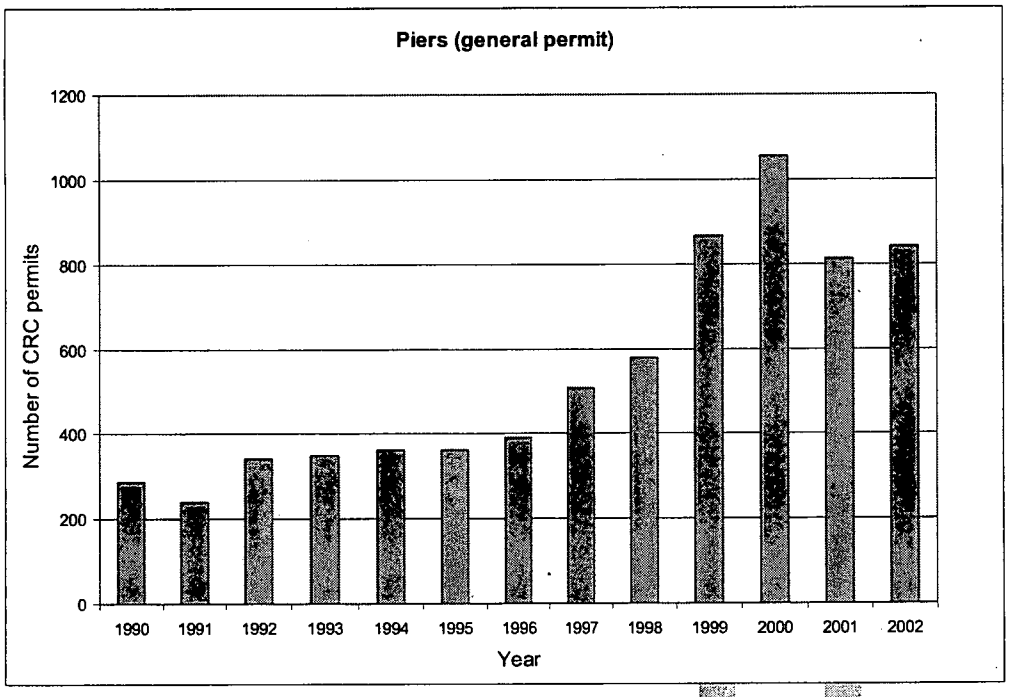

Figure 5.10. Annual number of CAMA general permits issued by the North Carolina Division of Coastal Management for piers. *(Source: DCM, unpub. data)*

Water quality degradation

Excess nutrients can result in undesirable changes in the wetland plant community (Lamers et al. 2002). The effect of changes in the plant community on fish use of wetlands is unknown. However, the effect of excess nutrients on fish use of wetlands could be more problematic. Algal blooms in and around emergent vegetation can cause very low dissolved oxygen levels at night, resulting in fish kills (see Chapter 2).

Another potential issue regarding the water quality of wetlands (especially freshwater marsh) is sulfate (SO_4^{-2}), a water-soluble, abundant form of sulfur that commonly occurs in nature (e.g., soil and minerals). Elevated sulfate concentrations can enter surface waters and eventually reach wetlands from a number of man-made sources, including: runoff from mining and agriculture, industrial waste discharge and atmospheric deposition (Lamers et al. 2001; Lamers et al. 2002; EPA 2002). Sulfates are used in a variety of industries, including, but not limited to, mining, processing (e.g., wood pulp, metal finishing, leather), sewage treatment, and manufacturing (e.g., chemical, dye, glass, textile, soap, insecticide, fungicide) (Greenwood and Earnshaw 1984 cited in EPA 2002). Approximately 30% of sulfate in groundwater may be from the atmosphere, while the remaining 70% is from organic processes (EPA 2002). In contrast, Moore (1991) reported that greater than 45% of sulfates detected in rivers originated from human activities. Dissolved or free sulfide (HS^-) can be highly toxic to rooted plants in freshwater wetlands where there is an insufficient amount of iron (Fe). Typically, sulfate-reducing bacteria convert sulfate to hydrogen sulfide (H_2S), pyrite (FeS_2), or iron sulfide (FeS). Sulfate over-enrichment may cause HS^- to accumulate in sediments, and the subsequent toxicity leads to rooted plant communities composed of a few highly sulfur-tolerant species. The effect of these changes in plant community structure on fish use of marsh wetlands is unknown. Lamers et al. (2002) demonstrated that FeS_x oxidation during desiccation, FeS_x oxidation due to nitrate pollution, and atmospheric sulfur (S) pollution threatened the water quality of freshwater wetlands via eutrophication and HS^- accumulation. The degree of HS^- accumulation did not vary among wetland soil types with different humus profiles (Lamers et al. 2001).

The susceptibility of freshwater wetlands to sulfate pollution should be evaluated in coastal North Carolina. Results should provide the measure of iron concentrations in wetland sediment necessary to evaluate susceptibility.

Introduced and nuisance species

A major non-native species issue concerning wetlands is the spread of *Phragmites* species (common reed) into salt/brackish marsh areas (Weinstein and Balletto 1999). Since the early 1900s, *Phragmites australis* has been replacing other salt/brackish marsh vegetation along the Atlantic coast at a rate of about 1% to 6% of the marsh surface per year (Weinstein and Balletto 1999). *Phragmites* forms dense, monotypic stands of vegetation that could alter fish use of the marsh. Recent research comparing fish use of *Phragmites* and *Spartina* marsh in New Jersey found no distinct habitat preference among large fish and decapod crustaceans (i.e., shrimp) (Able and Hagan 2000). On the other hand, *Phragmites* did have a negative effect on larval and juvenile fish abundance (Able and Hagan 2000; Able et al. 2003). A study in Connecticut salt marshes found no difference between use of reed-dominated tidal marshes and typical tidal marsh vegetation by mummichogs (Fell et al. 1998).

Sea level rise and storm events

Rising sea level is a major threat to coastal wetlands in North Carolina. Analysis of data from tide gauge stations in Hampton, Virginia, and Charleston, South Carolina, from 1921 to 2000 (Riggs 2001), show sea level rising along the Atlantic coast by about 3.35 mm per year (1.1 ft per 100 years). Gauge data specific to North Carolina are available only for 20 years, but suggest a slightly greater rate of approximately 4.57 mm per year (1.5 ft per 100 years). The combination of sea level rise and storm events causes erosion of wetlands at a rate of approximately 802 acres/year (Riggs 2001). The importance of coastal erosion is further emphasized by the relatively low amount of permitted coastal wetland impacts from 1999 to 2002 (WRP 2001), compared to estimated erosion losses. Compared to sea level rise, the rate of wetland building or accretion is slightly less, but of the same order of magnitude: approximately 1.20 mm per year (Hackney and Cleary 1987). Loss of wetlands from sea level rise is exacerbated along steeply sloping shorelines or where wetland migration is otherwise restricted (i.e., where bulkheads are present). A recent study of salt marsh response to sea level rise in New England found that low marsh vegetation (*Spartina alternaflora*) was replacing high marsh vegetation (*Spartina patens*, *Distichlis spicata*, and *Juncus gerardi*) (Donnelly and Bertness 2001). If the rate of sea level rise increases significantly over the next century, many low marsh areas in New England and elsewhere will likely drown (Donnelly and Bertness 2001). *Buyers and owners of coastal property should be aware of sea level rise and the potential for loss of wetlands and property. Updated and accurate coastwide estuarine erosion rates are needed for the CRC and EMC to determine adequate development guidelines and rules along the coast (CRC Estuarine Biological and Physical Processes Workgroup 2003). Priorities for coastal wetland protection should also acknowledge sea level rise, and protect gently sloping areas upland of coastal wetlands to allow for landward migration of coastal wetlands with sea level rise.*

Tropical storm surge events can degrade or erode low salinity wetlands by bringing in high salinity water, as well as flooding from rainfall. Freshwater species cannot tolerate high salinity, while salt/brackish species cannot tolerate the freshwater flooding, resulting in a total loss of wetland vegetation in some areas (Baldwin and Mendelssohn 1998). With rising sea level, the impact of storm events on dieback of coastal wetlands can be substantial (Riggs 2001). Loss of wetlands due to increasing salinity and flooding has been documented in Louisiana estuaries (Webb 1997). Loss of wetlands from storm surge events and erosion in North Carolina (Riggs 2001) did not distinguish losses due to vegetation dieback from overall erosion. Vegetation dieback is important because it could actually accelerate erosion of coastal wetlands. *Research is needed on site-specific erosion and accretion rates and their relationship with sea level rise and storm events (Brinson and Moorhead 1989). Specific research is also needed to determine processes that control the upper limits of peat accumulation, which is the foundation of coastal*

wetland development in the Albemarle-Pamlico system (Moorhead and Brinson 1995).

5.5. SUMMARY OF WETLAND CHAPTER

Wetland habitat is unique among the coastal fish habitats because it is not entirely submerged but occurs in and above the water. There are many different types of wetlands throughout the coast, many bordering the rivers and sounds, while others are hydrologically isolated. While each wetland type is unique, these different types provide similar ecological functions. Wetlands are highly effective and well recognized for their value as a natural filter, trapping and filtering pollutants from upland runoff; as well as serving to buffer the effects of floods by storing, spreading, and slowing stormwater runoff. Like SAV, wetlands are highly productive biologically, but because of their expansive coverage and biomass, produce much more organic matter, which is broken down and utilized by multiple species adjacent to wetlands and elsewhere. It has been estimated that over 95% of the United States' commercially harvested finfish and shellfish are wetland dependent. The combination of shallow water and thick vegetation provides excellent nursery habitat for juvenile fish. The majority of MFC-designated Primary Nursery Areas consists of wetlands and adjacent shallow water and soft bottom. Fish found commonly in or near freshwater marshes and swamps include bluegill, largemouth bass, river herring, and striped bass. In and adjacent to estuarine wetlands, killifish, spot, red drum, flounder, penaeid shrimp, striped mullet, pinfish, blue crab, and other species are abundant. In addition to supplying food and acting as nursery habitat for numerous species, riparian wetlands also provide a relatively safe corridor for fish moving among the other nearshore habitats.

It is estimated that as much as 40-50% of North Carolina's original wetland coverage has been lost, primarily due to ditching, channelization, and filling for agriculture and development. From the early 1800s to the early 1900s, agriculture accounted for the majority of wetland losses. From about 1950 to the 1990s, development accounted for two-thirds of wetland impacts, with forestry and agriculture associated with the remainder. Although the rate of wetland loss has slowed, losses continue to occur. Mitigation for permitted losses and voluntary restoration efforts in some areas have partially offset some recent losses, but the type of wetland gained is often not equivalent to what was lost. Degradation and loss of wetlands can impact many species, including overfished stocks of river herring, Atlantic sturgeon, and southern flounder, as well as blue crab and striped mullet stocks, which currently have a status of "Concern."

There are multiple threats to wetland habitat today, primarily due to physical destruction and hydrological alteration. Ditching and draining for forestry and development, construction of new dams, mining activity, and filling for new development accounted for the majority of permitted wetland losses in recent years. Construction of roads, infrastructure, and water dependent-development, including dredging for marinas and navigation channels, also results in smaller, site-specific losses and contributes to cumulatively large wetland losses. Estuarine shoreline stabilization causes gradual, long-term wetland loss by limiting sediment inputs needed for maintenance and expansion of wetlands, and by blocking landward migration as sea level rises. Forestry and agriculture also impact wetlands through hydrologic alterations, which are not tracked in the permitting database. Because wetlands are critical to a large number of fishery species, but have been greatly reduced in spatial coverage from their original extent, ongoing initiatives such as wetland restoration, land acquisition and preservation, and agricultural cost-share BMPs need to be enhanced. There should also be additional initiatives implemented to protect and enhance wetland habitat. The many fishery and water quality functions provided by wetlands make their preservation and restoration along North Carolina's coast a high priority for protection of all coastal fish habitats.

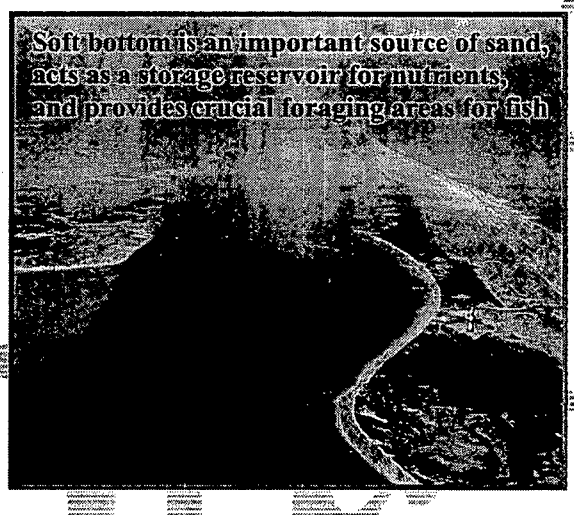
CHAPTER 6. SOFT BOTTOM

6.1 DESCRIPTION AND DISTRIBUTION

Definition

Soft bottom habitat is unconsolidated, unvegetated sediment that occurs in freshwater, estuarine, and marine systems. The MFC, CRC, or EMC do not specifically define soft bottom or unvegetated bottom in their regulations. The SAFMC defines one type of soft bottom, tidal flats, as "dynamic features of coastal landscapes whose distribution and character may change with shifting patterns of sediment erosion and deposition." This definition could in fact apply to all soft bottom. However, the CHPP definition of soft bottom includes deeper subtidal bottom as well as shallow bottom areas. Although soft bottom as a habitat type is not specifically designated or protected by any of North Carolina's regulatory commissions, it is an important component of MFC designated Primary Nursery Areas (PNAs), Anadromous Fish Spawning Areas, and Anadromous Nursery Areas.



Habitat requirements

Soft bottom has only one habitat requirement – sediment supply. Environmental characteristics, such as distribution of sediment grain size and distribution, salinity, dissolved oxygen, and flow conditions will affect the condition of the soft bottom habitat and the type of organisms that utilize it. Nevertheless, the habitat itself will persist regardless of its condition unless it becomes starved for sediment or is colonized by other organisms, transforming it into another habitat such as SAV or shell bottom. Refer to the threats section for more information on alterations to soft bottom habitat.

Description and distribution

Although soft bottom habitat is defined as "unvegetated" and lacks visible structural habitat, the surface sediments support an abundance of microscopic plants; numerous burrowing animals are hidden below the surface (Peterson and Peterson 1979). The characteristic common to all soft bottom types is the mobility of unconsolidated, uncemented soft sediment (Peterson and Peterson 1979). Soft bottom habitat can be characterized by geomorphology (the shape and size of the system), sediment type, water depth, hydrography (riverine, intertidal or subtidal), and/or salinity regime (DENR 2000a). Soft bottom habitat types in North Carolina's coastal waters can be categorized as the following:

Freshwater

- unvegetated shoreline

- river, creek, and lake bottom

Estuarine

- intertidal flats and unvegetated shoreline
- subtidal bottom in rivers, creeks, and sounds

Marine

- intertidal beach
- subtidal bottom

It is important to understand the physical and chemical properties of soft bottom habitat since this affects the benthic organisms that inhabit these areas and in turn, their value as fish habitat. The physical and chemical character of all soft bottom is determined by the underlying geology, basin morphology, and associated physical processes (Riggs 1996). Geologically, North Carolina's coast can be divided into distinct northern and southern provinces that are approximately separated by Cape Lookout (Riggs 1996; Pilkey et al. 1998). In the northern province, sediment formations generally consist of a thick layer of unconsolidated muds, muddy sands, sands, and peat sediments. A gently sloping depositional basin formed north of Cape Lookout. The low slopes of the northern province are characterized by an extensive system of drowned river estuaries (i.e., Albemarle Sound, Neuse River), long barrier islands, and few inlets (Map 6.1 a-e). In contrast, the southern coastal province has only a thin and variable layer of surface sands and muds, with many areas of exposed rock outcrops in marine waters. The southern province also has a steeper sloping shoreline, resulting in narrow estuaries (i.e., Topsail Sound, Batts Mill Creek), short barrier islands, and numerous inlets (Map 6.1 a-e). These geomorphic features, in turn, affect sediment deposition and the character of soft bottom habitat.

Freshwater bottom

Freshwater bottom includes the bottom sediments of freshwater rivers, creeks, and lakes. These areas were described in the Water Column chapter and are shown in Map 2.6a-b. Properties of the soft bottoms within a river system depend primarily on the origin of sediment inputs but also on elevation gradient, flow conditions, riparian cover, local geology, and water column characteristics. Upstream sources of sediment inputs into riverine systems include erosion of sediment bank shorelines, flushing of swamp forests and other wetlands, and transport of suspended sediment from upstream riverine flood waters (Riggs 1996). Bottom composition generally ranges from more consolidated material upstream (bedrock, boulders) to less consolidated material downstream (gravel, sand). Because freshwater rivers and creeks are eroding through older sediment banks, there tends to be a deep main channel dominated by medium-to-coarse grained sand with varying amounts of detritus. Shallow flats may exist on one or both sides of the channel. Sediment on these flats tends to consist of a layer of fine sandy mud on top of older sediments (Riggs 1996). Where the channel bed is relatively deep or wide, pools form and water velocity slows, allowing finer particles to settle (sand, silt). Where the channel bed is relatively narrow or shallow, riffles and runs occur and water velocity increases, leaving only the heaviest particles on the bottom (boulder, cobble). Dissolved oxygen in flowing waters is generally high, leading to aerobic surface sediments.

In freshwater lakes, like Lake Mattamuskeet, the shallow bottom around the shoreline is often unvegetated due to shoreline erosion, high wind exposure, or low water clarity (from turbidity or organic staining). In sheltered areas, however, the bottom may be covered by submerged aquatic vegetation. In deeper areas of lakes, the bottom is unvegetated because of low light availability. These deeper waters may become stratified during summer, causing anoxia or hypoxia on the bottom (Mitsch and Gosselink 1993).

Estuaries and sounds - intertidal flats, unvegetated shoreline and subtidal bottom

Sediment composition of soft bottoms in estuaries and sounds varies with geomorphology and position within the estuary. The basin morphology of most northern estuaries in North Carolina is similar to a

shallow, flat-bottomed dish with a small lip around the perimeter (Pilkey et al. 1998). The estuarine shoreline is a cut bank with a narrow and shallow perimeter platform (the lip) that slopes gradually away from the shoreline to approximately 3-7 ft (1.5-2 m) deep, and then more abruptly to the floor of the central basin. The central basins deepen gradually from the inner estuary to the outer estuary from about 12 – 23 ft deep (4 to 7 m). The central basins become shallow near the mouths of the estuaries due to formation of sandy bars, and behind the barrier islands due to storm overwash and transport of sand from the inlets. Coarse sands are concentrated on the shallow perimeter platforms, shoals, and inlet mouths, while fine sediments such as organic rich mud (ORM) are concentrated in the deeper central basins and downstream channels (Wells 1989; Riggs 1996; Pilkey et al. 1998) (Map 6.2). General bottom topography of estuarine water bodies is shown in Map 4.1. The relationship between sediment composition and water depth is evident when comparing Map 5.1 and Map 6.2. The width and thickness of ORM increase as the estuary widens and deepens in the downstream direction, since the fine sediments are easily suspended and transported away from high energy waters (Riggs 1996).

Soft bottoms in the northern geologic province, including the Albemarle-Pamlico Estuarine System, consist of four general types of sediment: sand, peat, inorganic mud, and ORM (Wells 1989; Riggs 1996). Sands are derived from erosion of the sediment bank shorelines and shallow perimeter platform throughout the estuaries. Sand is also transported into the lower portion of the estuaries from barrier island overwash and transport through the inlets. Peats (sediments with more than 40% organic matter) are derived from flushing of organic matter from wetlands and erosion of wetland shorelines. Inorganic muds consist of several clay minerals, primarily derived from suspended sediment transported from riverine flood waters to the estuarine system. Organic rich mud is the most extensive sediment type in North Carolina's estuaries. It is composed of 5 to 40% organic matter (most commonly about 10%), mixed with inorganic clay (approximately 76%) and quartz sand (approximately 13%). Organic rich mud comprises approximately 70% of the sediment in North Carolina's estuarine system and is primarily concentrated in the central basins of the sounds.

Soft bottom in the southern estuarine system is dominated by sloped mudflats on the perimeter and interior of the smaller estuaries (i.e., White Oak River, Pages Creek) (Pilkey et al. 1998). The mudflats are riddled with tidal channels and support extensive salt marshes. In the lower estuary, sand is transported into the estuaries from the numerous inlets and barrier island overwash. In the upper estuary, small blackwater streams carry relatively low sediment loads into these estuaries, but the water contains large quantities of dissolved organic matter that give it a brown tea color. The Cape Fear River, unlike the other smaller river systems in the Southern Province, transports large sediment loads from eroding clay sediments of the Piedmont to the lower estuary.

Unvegetated shorelines occur where wave energy prevents colonization by plants and there is a gently sloping area for sand to build upon (Riggs 2001). The shoreline provides an area to absorb the physical energy from waves, tides, and currents, protecting upland areas. Although unvegetated nontidal shorelines are ordinarily exposed from water, and therefore not used by fish, the dynamic processes of erosion and sediment deposition affect the composition and supply of sediment in adjacent shallow water habitats. This in turn affects the type and productivity of the benthic invertebrate community. For example, unvegetated sediment bank shorelines are generally eroding and sandy, providing a source of sand to adjacent waters (Riggs 2001). Sand deposits from inlet flood tide deltas and overwash events on back barrier islands form shallow sand flats behind the islands. In contrast, marsh or swamp forest shorelines are generally not eroding and have a high organic content, thus providing fine organic sediments to adjacent waters. Several shoreline erosion studies have been conducted along North Carolina's coast that provide information on the character and condition of intertidal, shoreline, and shallow subtidal soft bottom and were compiled and summarized in Riggs (2001).

Intertidal flats are the unvegetated bottoms of estuaries and sounds that lie between the high and low tide lines. These flats occur along mainland or barrier island shorelines or can emerge in areas unconnected

to dry land. Intertidal flats are most extensive where tidal range is greatest, such as near inlets and in the southern portion of the coast. Because the influence of lunar tides is minimal in the large sounds (e.g., Pamlico, Albemarle, and Currituck), true intertidal flats are not extensive, except for the area immediately adjacent to inlets (Peterson and Peterson 1979). Sediment composition on intertidal shorelines tends to shift from coarser, sandy sediment on higher portions of the shoreline, with greater wave energy, to finer, muddier sediments in the lower portion of the shoreline, with relatively less wave energy (Peterson and Peterson 1979). Conditions on intertidal flats are physically stressful for associated marine organisms. Drastic fluctuations in salinity, water and air temperature (in addition to air and wind exposure) occur during each tidal cycle. Due to physiological restraints and limited water depth, some mobile organisms are restricted to deeper waters or adjacent habitats to avoid the stressful extremes associated with low tide. However, the sediment provides a buffer from changes in temperature and salinity in the water column for benthic infauna (Peterson and Peterson 1979).

The inlets separating North Carolina's barrier islands are part of a sand-sharing system among the islands, estuaries, and nearshore ocean. Intertidal flats or deltas form on the ebb and flood sides of inlets as sediments shift with tides and waves. Sediments in the vicinity of inlets are typically composed of coarse sands and shell fragments (Peterson and Peterson 1979). Ebb-tidal and flood-tidal deltas (i.e., the seaward and estuarine shoals of an inlet, respectively) are formed by waves and currents, and may contain large volumes of sand. Intense wave and current energy cause the flats to continually change, erode, and reform. The high instability of the ebb and flood tide deltas makes colonization by benthic invertebrates difficult (Peterson and Peterson 1979). Inlets are classified as stable, migrating, or ebb-tidal delta breaching (Fitzgerald et al. 1978). Unstable inlets may form extensive spits, tidal deltas, and sand bars, creating bathymetric complexity (or differences in water depth) in nearshore waters, that attract some fish species. The process of channel realignment and abandonment provides a mechanism for large sandbar complexes to move onto the adjacent barrier islands, supporting productive intertidal beach communities (Cleary and Marden 1999).

There are currently 20 inlets in North Carolina that connect estuarine waters to the sea (Map 6.3 a-c). Ten of these inlets originated as a result of storm breaches across barrier spits or islands and remain spatially unstable, including Oregon and Mason inlets (Cleary and Marden 1999). Mason Inlet, which has been migrating south rapidly, was artificially relocated in the winter of 2002. Mad and New (Corncake) inlets closed following the hurricanes of the last few years, and Old Drum Inlet reopened. A new inlet breached between Hatteras and Frisco during Hurricane Isabel in 2003, but was refilled by the United States Army Corps of Engineers (COE). There are nine larger inlet systems, including Ocracoke, Bogue, and the Cape Fear River inlets, which occupy ancient river channels. Two other inlets were artificially created: Drum and Carolina Beach inlets. Although originating as a storm-related breach, Tubbs Inlet was artificially relocated in 1970.

Ocean intertidal beaches and subtidal bottom

The locations of major marine intertidal and subtidal topographic features, such as beaches, inlets, inlet-associated ebb-tidal deltas, and shoals, are indicated in Map 6.1 a-e. The seafloor off the North Carolina coast is part of the Atlantic continental shelf, which slopes gradually from the coastline before dropping off steeply at approximately the 50 – 75 m isobath where the continental slope begins. In North Carolina, the continental shelf is relatively narrow, approximately 30 km off Cape Hatteras, 60 km off Cape Lookout, and about 90 km off Cape Fear. Water depth at the seaward limit of state territorial waters ranges from 50 to 70 feet (Map 6.1 a-e). Because North Carolina is located at a transition between two major physiographic and zoogeographic zones, the marine subtidal bottom supports a high diversity of invertebrates.

North of Cape Hatteras, the shoreline and adjacent shoals tend to be linear, the shelf is relatively steep, and the bottom consists of a regional depositional basin known as the Albemarle Embayment, resulting in few exposed rock outcrops. Several prominent shoals, such as Wimble, Kinnekeet, and Platt shoals also

occur in this region, as well as a series of prominent ridges and swales that are spaced about 400 – 600 m apart, with mean relief of 1 to 7 m, averaging 2 to 3 m in height (Inman and Dolan 1989; Rice et al. 1998). Shoals closest to shore, such as Wimble and Kinnekeet shoals, tend to be oriented at a 20 – 30° angle from the coastline, while those further offshore run more parallel to the coast (MMS 1993).

The coastline south of Cape Hatteras consists of a series of arcs, dominated by three major capes (Hatteras, Lookout, and Fear) and three associated bays (Raleigh, Onslow, and Long) (Map 6.1 a-e). Long Bay continues into South Carolina to Cape Romain. Large shoals extend across the shelf from each cape (Diamond, Lookout, and Frying Pan shoals) for more than 20 km. South of Cape Hatteras, the Continental Shelf has a greater amount of exposed rock outcroppings and is intersected with younger sediments originating from filled ancient river valleys (Riggs et al. 1995). The rock outcroppings are discussed in the hard bottom section of this plan.

The continental shelf off North Carolina has a relatively low supply of incoming sand due to low direct river input, entrapment of most river-borne sediment in the upper estuaries and sounds, and minimal sediment exchange between adjacent shelf embayments (Riggs et al. 1998). The shoreface is the generally concave, upward surface extending from the surf zone to the point where the slope matches that of the continental shelf (Thieler et al. 1995). The base of the shoreface off North Carolina occurs at approximately 10 – 12 m water depth. The shoreface represents the area of active beach sand movement. Six classes of shoreface systems were recognized by Riggs et al. (1995) based on differences in the underlying geology. The nature of these shorefaces affect the geologic composition of the surface and underlying substrate of the subtidal bottom and shoreline and partially explain the patterns of localized erosion or deposition.

The intertidal zone of oceanfront barrier island beaches is the area periodically exposed and submerged by waves, varying with frequency and with lunar tide cycles. In this high energy area, waves continually rework and sort sediment by grain size. The uprush of water carries sediment onto the beach, with larger sediments deposited first and finer-grained sediment carried farther landward. The backwash carries some sediment back into the water. Because of this regular high wave energy, as well as occasional storm events associated with extreme wave action, the intertidal beach and surf zone typically have rapid scour and fill events. The sediments are generally much coarser, more highly sorted, and contain less organic matter than in protected estuarine intertidal flats (Donoghue 1999).

The surf zone is the shallow subtidal area of breaking waves seaward of the intertidal beach. Within the surf zone, longshore sandbars frequently develop and shift seasonally in response to wave energy. Seaward of the surf zone, the subtidal bottom consists of a series of minor ridges and swales. Ripple scour depressions, ranging from 40 to 100 m in width and up to 1 m in depth, occur along the southern portion of the coast and are perpendicularly oriented to the beach, extending to the base of the shoreface (Thieler et al. 1995; Reed and Wells 2000). These features are located adjacent to areas experiencing chronic severe beach erosion, and may be indicative of rapid offshore transport of sand during storms (Thieler et al. 1995).

Three major shoals extend perpendicular to Cape Hatteras, Cape Lookout, and Cape Fear: Diamond Shoals, Cape Lookout Shoals, and Frying Pan Shoals, respectively. Water depth on the shoals ranges from 2 – 18 ft, in contrast to adjacent waters that are 20 – 40 ft deep. Due to an interest in beach nourishment projects for Dare County, Boss and Hoffman (2000) collected detailed information on the sand resources of North Carolina's Outer Banks, including specific data about Diamond Shoals. Diamond Shoals extend approximately 20 km (11 nautical miles or nm) and are about 11 km (5.5 nm) wide. The estimated total volume of sand on the shoal was at least 1.66 billion cu yd, with approximately 256 million cu yd within state waters (Boss and Hoffman 2000). As such, cape shoals are major sand resources for coastal processes. Detailed mapping of the bottom has been done in other areas of the coast to varying extent with different techniques. *The results of these studies need to be compiled in a*

comprehensive and comparable manner to evaluate changes and trends in substrate character, as well as feasibility of beach nourishment projects.

6.2 ECOLOGICAL ROLE AND FUNCTIONS

Community structure

Freshwater

The freshwater benthic community varies greatly from extreme headwaters to mainstem rivers and may be more similar to that found in inland lake bottoms than in estuaries. Green algae and diatoms are more common than dinoflagellates (Rulifson et al. 1986). In headwater streams, algal production is negligible where there is complete tree canopy cover and the benthic community consists largely of organisms that break down and collect detritus. As the canopy opens up downstream, algae grazers and detritivores increase in abundance (Vannote et al. 1980). Mussels are an important component of the invertebrate community in freshwater soft bottom. There are over 60 species of freshwater mussels in North Carolina. The distribution and diversity of native freshwater mussels has been in a state of decline in North Carolina as well as in other southeastern states. The freshwater Asiatic clam (*Corbicula fluminea*), introduced about 50 years ago, has become a prominent component of many rivers (Lauritsen and Moxley 1983). Ecological problems associated with this non-native species include alteration of the benthic substrate, and competition with native mussels and other mollusks (Devick 1991). Zebra mussels (*Dreissena polymorpha*) have not been reported in North Carolina, but have been found in Virginia and 20 other states. Due the rapid rate that this non-native has spread in the United States since first found in 1986, researchers feel that zebra mussels are likely to infest all southeastern states eventually, with negative impacts to the native mollusks (Neves et al. 1987). Freshwater benthic sampling, conducted by DWQ in all of North Carolina's river basins, provides detailed information on the abundance and diversity of benthic species present in the freshwater portion of North Carolina's coastal rivers.

Estuarine

Benthic microalgae are a key part of the food chain in estuarine soft bottom habitat. Benthic microalgae are microscopic photosynthetic algae that live in the top few millimeters of the surface of soft bottom (Miller et al. 1996). Because the unvegetated bottom appears barren, but is actually rich in photosynthetic algae, MacIntyre et al. (1996) referred to benthic microalgae as "The Secret Garden." Benthic microalgae on sand, mud flats, and subtidal bottom are composed primarily of benthic diatoms and blue green algae, with benthic dinoflagellates and filamentous green algae also present (Peterson and Peterson 1979). Dense mats of blue green algae sometimes form in protected higher portions of intertidal flats, giving the sediment surface a dark brown or blue-green appearance, which can form a crusty mat when dry at low tides (Peterson and Peterson 1979). Diatom mats are more abundant in the lower intertidal zone (Peterson and Peterson 1979). Benthic microalgae can either be attached to sediment particles or be mobile, migrating vertically through the sediment. Productivity depends on photosynthesis by these microalgae, which can only occur in sediments having adequate light penetration (MacIntyre et al. 1996). Photosynthetically active light generally penetrates only about 2-3 mm into the sediment, but can reach 5-20 mm in sandy, high energy environments.

Most benthic invertebrates inhabiting soft bottom live in the sediment (infauna), as opposed to the bottom's surface (epifauna), because of the high mobility of sediments (Peterson and Peterson 1979). These animals are classified by size and feeding mode. Microfauna are the very small protozoans (< 0.06 mm). Meiofauna are about 0.06 – 0.40 mm in size (the size of a sand grain), and include nematodes and copepods. Both microfauna and meiofauna are important grazers on benthic microalgae and bacteria. Macrofauna (>0.5 mm) contribute the most to infaunal biomass and include organisms such as amphipods, polychaetes, mollusks, echinoderms and crustaceans (Peterson and Peterson 1979). These macrofauna may be deposit feeders or suspension feeders (Peterson and Peterson 1979; Miller et al. 1996). Deposit feeders ingest sediment and detrital deposits and assimilate bacteria, fungi, and

microalgae from them. Compared to detritus and larger plants, microalgae may be a nutritionally richer food source for benthic invertebrates (Miller et al. 1996). Deposit feeders include mud snails, many polychaete worms, and certain bivalve clams and crustaceans.

Suspension feeders capture particles suspended in the water column. Common suspension feeders are bivalves such as the hard clam (*Mercenaria mercenaria*) and razor clam (*Tagelus plebeius*), and some polychaete worms (Miller et al. 1996). When sediment is resuspended, the benthic microalgae become available to the suspension feeders (Miller et al. 1996). A large proportion of intertidal bivalves' diet has been shown to consist of suspended benthic microalgae, particularly when chlorophyll concentrations in the water column are low (Page and Lastra 2003). While resuspended benthic microalgae can be beneficial to the invertebrate community as an additional food source, excessive suspended sediment and associated algae have been found to reduce growth rates and survival of macrofauna, such as hard clams (Bock and Miller 1994). Although the abundance of food sources affects invertebrate populations, benthic predators (such as spot and pinfish) were found to have a larger influence on soft bottom community composition and biomass relative to that of nutrient availability (Posey et al. 1995).

Larger, mobile invertebrates live on the surface of soft bottom. Fiddler crabs (*Uca* spp.) congregate on intertidal flats foraging for microalgae and detritus, and amphipods and insects also graze on the flats. On submerged flats and shallow bottom, blue crab (*Callinectes sapidus*) is an important predator. Other mobile invertebrates include horseshoe crab (*Limulus polyphemus*), whelks (*Busycon* spp.), tulip snails (*Fasciolaria* spp.), moon snails (*Polinices duplicatus*), penaeid shrimp (*Penaeus* spp.), hermit crabs (*Pagurus* spp., *Petrochirus* spp., and *Clibanarius vittatus*), sand dollars (*Mellita quinquiesperforata*), and spider crabs (*Libinia* spp.). Overall, estuarine soft bottom supports a high diversity of benthic invertebrates, with over 300 species documented in the southern portion of North Carolina (Hackney et al. 1996).

Marine

On oceanfront beaches, most benthic animals in the intertidal zone consist of infaunal burrowing forms. A diverse assemblage of meiofauna (0.06 – 0.4 mm in size) occurs in the lower beach community and acts as an important food source for many juvenile fish (Levinton 1982; Hackney et al. 1996). A relatively low diversity of macrofauna (>0.5 mm in size) (~ 20 – 50 species) exists in the intertidal beach compared to estuarine intertidal flats (~ 300 – 400 species) (Hackney et al. 1996). The dominant macrofauna by biomass in North Carolina's oceanfront intertidal beaches are mole crabs (*Emerita talpoida*) and coquina clams (*Donax variablis, D. parvula*) (Hackney et al. 1996; Donoghue 1999; Peterson et al. 2000). Several species of amphipods and the spionid polychaete (*Scolelepis squamata*) have been reported as highly abundant on some beaches as well (Lindquist and Manning 2001).

Polychaete worms, isopods, mollusks, echinoderms, amphipods, and other crustaceans occur in sediments in the oceanfront intertidal beaches, cape and ebb tide shoals, surf zone and other subtidal bottom (Jutte 1999; Peterson et al. 1999). Three general groups of polychaetes occur in intertidal beaches (Hackney et al. 1996): a) burrowing deposit feeders, including thread worms (*Lumbrineris* sp., *Scolelepsis* sp.), and red-lined worms (*Nepthys* sp.); b) suspension feeders; and c) tube building burrow dwellers, such as plumed worms (*Diopatra* sp.) and lugworms (*Arenicola* sp.). Offshore sand bottom communities along the North Carolina coast are relatively diverse habitats containing over a hundred polychaete taxa (Posey and Ambrose 1994; Lindquist et al. 1994). Tube dwellers and permanent burrow dwellers are important benthic prey for fish and epibenthic invertebrates. These species are also most susceptible to sediment deposition, turbidity, erosion, or changes in sediment structure associated with sand mining activities, compared to other more mobile polychaetes (Hackney et al. 1996). In South Carolina, 243 species of benthic invertebrates were documented in the nearshore subtidal bottom (Van Dolah et al. 1994). Polychaetes and amphipods were the most abundant, although oligochaetes, bivalves, and crabs were also highly represented (Van Dolah et al. 1994). On ebb tide deltas, polychaetes, crustaceans (primarily amphipods), and mollusks (primarily bivalves) were the most abundant infauna, while decapod

crustaceans and echinoderms (sand dollars) dominated the epifauna. Many faunal species documented on the ebb tide delta are important food sources for demersal predatory fishes and mobile crustaceans, including spot, croaker, weakfish, red drum, and penaeid shrimp. These fish species congregate in and around inlets during various times of the year (Peterson and Peterson 1979), presumably to enhance successful prey acquisition and reproduction.

Productivity

Freshwater and estuarine

Production of organic matter in North Carolina's estuarine system is derived from several primary producers, including phytoplankton in the water column, detritus from wetlands and submerged grasses, and benthic microalgae and macroalgae on soft bottoms and other structure (Currin et al. 1995; Wainright et al. 2000). Of these, benthic microalgae have only recently been recognized as an important source of primary production in estuarine systems (Pinckney and Zingmark 1993; MacIntyre et al. 1996; Cahoon and Cooke 1992; de Jong and Van Beusekom 1995). Benthic microalgae are the major food source for deposit feeders such as mud snails, certain bivalve clams, and many polychaete worms (MacIntyre et al. 1996). Chlorophyll *a* biomass and carbon productivity rates are often used as indicators of overall productivity. In North Carolina estuaries, values for chlorophyll *a* biomass from soft bottom has varied widely but generally ranged from 10-90 mg/m^2 (Posey et al. 1995). Similar ranges were found in other Atlantic coast states (Table 6.1). Production rates in North Carolina are thought to be similar to that reported for Delaware and South Carolina (Table 6.1) (C. Currin, NMFS, pers. com., 2004). In flowing freshwater creeks and rivers, little information is available in the scientific literature on benthic productivity. In general, primary production in these freshwater areas is greatest in shallow, well-illuminated benthic substrates.

Table 6.1. Benthic productivity estimates in Virginia and Delaware (Chesapeake Bay), North Carolina (Masonboro Sound), and South Carolina (North Inlet Estuary).

Region	Chl. *a* biomass (mg/m^2)	Carbon production (gC/m^2/yr)	Reference
Virginia	5 – 65	-	Rizzo and Wetzel (1985)
Delaware	-	79 – 99	Rizzo and Wetzel (1985)
North Carolina	10 – 90	-	Posey et al. (1995)
South Carolina	20 – 110	56 – 234	Pinckney and Zingmark (1993)

The most productive estuarine bottom, in terms of benthic microalgae, tends to be protected and shallow areas with muddy/fine sand (Pinckney and Zingmark 1993; MacIntyre et al. 1996). Productivity is generally lower in exposed areas, deep areas, or on coarse sand bottom (MacIntyre et al. 1996; Sundback et al. 1991; Chester et al. 1983). In the upper reaches of the estuary, where the bottom consists of soupy mud/silt, productivity declines because of the instability of the fine sediment and greater frequency of high turbidity (M. Posey, UNC-W, pers. com., 2003). Many of the typically productive areas of soft bottom, in terms of benthic microalgae, are also productive fish nursery areas. In shallow intertidal bottom, primary production may be greater than in the water column, while in deeper subtidal bottom, benthic production may be slightly less than in the water column (MacIntyre et al. 1996). In the Newport River estuary, benthic diatoms were found to be resuspended into the water column following wind or rain events, greatly altering the composition and abundance of plankton in the water column (Tester et al. 1995). Since there is a large and ongoing exchange of sediment, algae, and nutrients between the soft bottom and water column (benthic-pelagic coupling), especially in shallow waters, it is difficult to distinguish between productivity in the water column versus soft bottom (Cahoon and Cooke 1992; MacIntyre et al. 1996).

Factors that control the magnitude and variability of benthic primary productivity on soft bottom include

temperature, light availability, sediment grain size, and community biomass (amount of chlorophyll present) (Pinckney and Zingmark 1993; Barranguet et al. 1998; Guarini et al. 2000; Cahoon et al. 1999). Since the depth to which benthic microalgae photosynthesize is determined by light, most researchers consider light the major factor affecting primary production rates (MacIntyre et al. 1996). Nutrients are not thought to limit productivity in soft bottom habitat because bacteria quickly convert detritus to inorganic nutrients (remineralization), making nutrients readily available in the sediment (Peterson and Peterson 1979; Admiraal et al. 1982).

In addition to primary productivity from benthic microalgae, organic matter on soft bottom habitat is derived from detrital matter from marsh vegetation, submerged grasses, and macroalgae that settles on soft bottoms (Currin et al. 1995; Wainright et al. 2000). In a South Carolina estuary, benthic microalgae accounted for approximately 22 – 38% of the primary production, with marsh vegetation accounting for approximately 30 – 59% and phytoplankton accounting for approximately 15 – 27%. The relative contribution of different primary producers varies by the diet preference of individual fish or invertebrate species, their position within the estuary, and seasonal and episodic weather conditions (Tester et al. 1995; Wainright et al. 2000; Page and Lastra 2003). Each source of primary production contributes to the estuarine food web. This web supports large numbers of benthic invertebrates, which are the primary food base for North Carolina's bottom feeding larval, juvenile, and adult fish and invertebrates (Peterson and Peterson 1979).

Marine

In the surf zone, inorganic nutrients are continually resuspended by wave action and retained by circulation patterns in sufficient amounts to create localized phytoplankton blooms, particularly composed of diatoms (McLachlan et al. 1981; Hackney et al. 1996). This self-sustaining nutrient input drives phytoplankton production, which supports intertidal filter feeders and, consequently, high concentrations of baitfish and estuarine dependent fish migrating through the shallow waters of the surf zone. Benthic invertebrates in the subtidal bottom of the surf zone and inlets provide an important link between primary producers and predators, such as demersal fish and crustaceans. Many of these predators have high economic value in recreational and commercial fisheries. Peterson and Peterson (1979) compiled a list of the diets of many common fish that forage in the intertidal flats. Some of the species that forage on benthic invertebrates in the surf zone and shoals include inshore lizardfish, pompano, pigfish, pinfish, spot, kingfish, red drum, Atlantic croaker, northern sea robin, and summer flounder. Additional information on fish utilization of the surf zone is discussed in the water column section of this plan.

Benthic microalgae on subtidal bottom in the coastal ocean are an important source of primary production. Viable chlorophyll *a* occurs in sediments across the continental shelf in Onslow Bay (Cahoon et al. 1990). Studies in Onslow Bay have found that roughly 80% of the chlorophyll *a* in the bay was associated with microalgae in or on the sediment. Benthic microalgal biomass (36.4 mg chlorophyll *a*/m^2) exceeded phytoplankton biomass (8.2 mg chlorophyll *a*/m^2). Gross benthic microalgal production averaged 24.9 mg carbon/m^2/hr, compared to 27.4 mg carbon/m^2/hr integrated water column phytoplankton production (Cahoon and Cooke 1992). Benthic microalgal production also surpassed integrated phytoplankton production primarily in the summer months, when light flux to the bottom is greater and phytoplankton biomass is generally lower. Pennate diatoms dominate the benthic microflora. These microalgae are grazed by demersal zooplankton, meiobenthos, and other macrofauna.

Ecosystem Enhancement

Soft bottom plays a very important role in the ecology of estuarine ecosystems as a storage reservoir of chemicals and microbes. Intense biogeochemical processing and recycling establishes a filter to trap and reprocess watershed-derived natural and human-induced nutrients and toxic substances. These materials may pass through an estuary (Mantoura and Woodward 1983), become trapped in the organic rich oligohaline (low salinity) zone (Sigels et al. 1982; Imberger et al. 1983), or migrate within the estuary

over seasonal cycles (Uncles et al. 1988). The fate of the materials depends upon salinity gradients, which are driven by freshwater discharges, density stratification, and formation of salt wedges (Matson and Brinson 1985, 1970; Paerl et al. 1998). Density gradients (stratification) hamper mixing and oxygen exchange of sediments and water in bottom waters with overlying oxygenated waters, leading to depletion of dissolved oxygen in bottom water (Malone et al. 1988).

In North Carolina's slow-moving, expansive estuaries, nutrients and organic matter from the watershed runoff and phytoplankton production are stored in the soft bottoms. Depending upon freshwater discharge and density stratification, these materials are recycled within the sediments via microbial activities and from the sediments into the overlying waters. Increased inflows of nutrients exacerbate the process, leading to more rapid and expanding dissolved oxygen depletion. In organic enriched oligohaline zones (e.g., Pamlico and Neuse River estuaries), nutrient-induced recycling results in higher microbial activity and oxygen depletion (B.J. Copeland, NCSU, pers. com., 2004).

Although soft bottom habitat is composed of unconsolidated shifting sediments, colonization by benthic microalgae reduces the extent to which sediment is resuspended at low velocities, stabilizing bottom sediments and reducing turbidity in the water column (Holland et al. 1974; Underwood and Paterson 1993; Yallop et al. 1994; Miller et al. 1996). In spite of this, microalgae cannot stabilize sediments under intense or prolonged disturbance conditions, such as during large storm events or in the surf zone (Miller 1989). Structure from tube dwelling invertebrates also helps to bind the sediment (Peterson and Peterson 1979), while filtering activity of dense aggregations of suspension feeders (hard clams) clears significant amounts of plankton and sediment from the water column and improves water clarity (Miller et al. 1996). Yet, because of the absence of large, extensive structure, soft bottom provides relatively less stabilization benefits than other estuarine habitats.

Intertidal shorelines, flats, tidal deltas, and sand bars along the ocean shoreline, buffer and modify wave energy, reducing shoreline erosion. Alterations to the ebb and flood tide deltas can result in significant changes in the adjacent barrier island shorelines. Flood-tidal deltas are an important source of sand, which allows barrier island migration to respond to sea level rise (Cleary and Marden 1999). The soft bottom associated with inlets has a great influence on overall barrier island dynamics.

Fish utilization

Like the water column, soft bottom is used to some extent by almost all native coastal fish species in North Carolina. However certain species are better adapted to, characteristic of, or dependent on shallow unvegetated bottom. Flatfish, rays, and skates are well suited for utilization of soft bottom. Juvenile and adult fish species that forage on the rich abundance of microalgae, detritus, and small invertebrates are highly dependent on the condition of soft bottom. Table 6.2 summarizes important fishery and nonfishery species that are dependent on subtidal bottom for some portion of their life history and the ecological function of the soft bottom habitat.

Foraging

One of the most important functions of soft bottom habitat is as a foraging area. Members of several trophic levels in the benthic community benefit directly or indirectly from a) the high concentrations of organic matter transported to and produced on soft bottom and b) the numerically abundant, diverse invertebrate fauna associated with soft bottom – including herbivores (e.g., planktonic and benthic algal feeders), detritivores, predators of benthic invertebrates and fish (secondary consumers), and predators of those predators (tertiary consumers) (Peterson and Peterson 1979).

Table 6.2. Partial list of common or important fish species occurring on soft bottom habitat in riverine, estuarine, and ocean waters, and ecological functions provided to those species. Bolded species indicate relatively higher association on soft bottom habitat.

[6] Uses surf zone almost exclusively as nursery area

[7] Former fishery, but fishing moratorium since 1991

Both plankton and benthic feeding herbivorous fish are found in abundance on intertidal flats. Schools of baitfish, small pelagic fish that tend to group together, are common over subtidal soft bottom and very abundant on shallow intertidal flats. These baitfish, such as anchovies, killifish, and menhaden, feed on the abundant supply of phyto- and zooplankton in the water column, but also consume resuspended benthic algae, microfauna, and meiofauna (Peterson and Peterson 1979). Although the majority of detritivores of the soft bottom habitat are invertebrates, striped mullet, white mullet, and pinfish also feed on detritus on subtidal bottom and intertidal flats. Other fish species use detritus as an alternate food source when preferred items are not available.

Most fish that forage on soft bottom are predaceous. Predators of benthic invertebrates include juveniles and adults of the following species (Peterson and Peterson 1979; Bain 1997):

- rays and skates,
- flatfish (southern flounder, summer flounder, hogchoker, tonguefish),
- several species of drum (spot, croaker, red drum, kingfishes, silver perch),
- Florida pompano,
- pigfish,
- sea robins,
- lizardfish,
- spadefish,
- gobies, and
- shortnose and Atlantic sturgeons.

The compressed body forms of flatfish, rays, and skates assist in prey acquisition and predator avoidance on shallow intertidal flats (Peterson and Peterson 1979). For example, flounder forage on shallow flats by laying still, by concealing themselves under a thin layer of sediment, or by changing skin color. Small flatfish, including the bay whiff, fringed flounder, hogchoker, and tonguefish, feed mostly on copepods, amphipods, mysids, polychaetes, mollusks and small fish. By way of comparison, summer and southern flounder primarily consume fish, such as silversides, and anchovies, as well as shrimp and crabs, small mollusks, annelids, and amphipods (Peterson and Peterson 1979). Various rays excavate large pits while feeding, creating slightly deeper pockets of water that other fish and invertebrates use as refuge. Mollusks, annelids, crustaceans, and fish comprise the typical diet of rays.

To avoid predation, small fish commonly feed on open, unvegetated bottom at night and hide near structure during the day (Peterson and Peterson 1979). Larger predators that feed on smaller, benthic-feeding fish and invertebrates typically move onto the flats during high water to feed on schools of fish. These predators include sharks (sandbar, dusky, smooth dogfish, spiny dogfish, Atlantic sharpnose, scalloped hammerhead), drum (weakfish, spotted seatrout), striped bass and estuarine dependent reef fish (black sea bass, gag grouper, sand perch, sheepshead) (Peterson and Peterson 1979; Thorpe et al. 2003).

Due to their size and shape, small baitfish and flat bodied rays, skates, and flounders have a feeding advantage over other fish in that they can forage on intertidal flats for greater amounts of time than larger fish. These fish groups are considered to be most characteristic of intertidal flats and would be most affected by habitat degradation and loss of intertidal flats from dredging, filling, bulkheading, or other anthropogenic causes (Peterson and Peterson 1979).

Fish species and age composition over soft bottom varies seasonally. Baitfish are present on shallow flats throughout the year. In the spring, large schools of baitfish are joined by juvenile fish that were spawned offshore in the winter (spot, croaker, menhaden). In the summer, these species remain abundant on shallow unvegetated bottom; flatfish and rays also appear at this time. By fall, fish species diversity is at a maximum since summer residents and fall migrants are both present. Migratory fish feeding on the soft

bottom include bluefish, striped mullet, kingfish, spotted seatrout, red drum, and many others (Peterson and Peterson 1979).

Ocean subtidal bottom serves as important foraging grounds for numerous fish species, particularly for Florida pompano, red drum, kingfish, spot, and Atlantic croaker, weakfish, and striped bass. Many commercially or recreationally important fish and invertebrate species, such as red drum, striped bass, shrimp, and summer flounder, are caught while they aggregate and feed over subtidal bottom in nearshore ocean waters. These species appear to be strongly associated with distinct topographic features of the subtidal bottom, such as the cape shoals, channel bottoms, sandbars and sloughs. *The natural processes that create these features need to be maintained. Additional public outreach is needed to emphasize the importance of natural barrier island and estuarine processes.*

The food resources present in and on soft bottom are needed to support hard bottom fish species. Demersal zooplankton and infaunal macroinvertebrates from sand substrate have been found to be a quantitatively important component of many species' diets and an important link to reef fish production (Cahoon and Cooke 1992; Lindquist et al. 1994; Thomas and Cahoon 1993). Reef species documented foraging over sand bottom away from the reef include tomtate (*Haemulon aurolineatum*), whitebone porgy (*Calamus leucosteus*), cubbyu (*Equetus umbrosus*), black sea bass (*Centropristis striata*), and scup (*Stenotomus chrysops*) (Lindquist et al. 1994). Therefore, benthic microalgal production on the subtidal bottom of Onslow Bay, as well as other similar shelf habitats, is an important component to the continental shelf productivity and is an important link to the ecology of hard bottom habitats.

Spawning

Many demersal fish spawn over various areas of soft bottom habitat in North Carolina's coastal waters (Table 6.2). In fresh water, resident species such as largemouth bass (*Micropterus salmoides*) and bluegill (*Lepomis macrochirus*) spawn on shallow flats where they lay eggs in bowl-shaped nests. Eggs may be dependent on the small structure available on the unvegetated bottom, such as emerging worm tubes or woody debris, to hold them in position. Since all life stages of freshwater resident fish (spawning adults, eggs, larvae, juveniles) remain near the same area of soft bottom habitat, they are relatively more vulnerable to degraded soft bottom habitat conditions than migratory species. Anadromous species, such as Atlantic and shortnose sturgeon (*Acipenser oxyrinchus oxyrinchus* and *A. brevirostrum*, respectively), spawn in upper freshwater portions of coastal rivers (Moser and Ross 1995).

Estuarine spawners include resident fish and invertebrates, as well as migratory fish that are summer estuarine spawners. Estuarine resident species include common invertebrates that occupy the intertidal flats, like hard clams, whelks, snapping shrimp, and hermit crabs. Small schooling baitfish such as mummichogs and striped killifish spawn in the marsh edges near soft bottom (Hildebrand and Schroeder 1972; Mannoch 1984). Species of flatfish, including the windowpane, and hogfish have been reported to spawn on estuarine soft bottom (Hildebrand and Schroeder 1972; Mannoch 1984).

Summer estuarine spawners include several species of drum. Weakfish and silver perch were documented spawning in deep estuarine channels near Pamlico Sound inlets (Ocracoke and Hatteras inlets) and in deep areas of Pamlico Sound from May to September, peaking in May and June (Luczkovich et al. 1999). Spotted sea trout spawn on the east and west sides of Pamlico Sound during a similar time period, with peak activity observed around July. Specific spawning areas for spotted sea trout identified on the west side of Pamlico Sound were Rose Bay, Jones Bay, Fisherman's Bay, and Bay River (Luczkovich et al. 1999). Red drum were documented spawning in the mouth of the Bay River on the west side of Pamlico Sound, and in estuarine channels near Ocracoke Inlet (Luczkovich et al. 1999). Blue crabs also spawn near inlets in summer (DMF 2000).

Several species of sharks pup in North Carolina's nearshore ocean waters. North of Cape Hatteras, pupping of spiny dogfish over subtidal bottom has been documented in winter months (W. Laney,

USFWS, pers. com., 2003). Subtidal bottom in the southern portion of North Carolina state waters serves as pupping grounds for the Atlantic sharpnose shark (*Rhizoprionodon terraenovae*), bonnethead shark (*Sphyrna tiburo*), blacknose shark (*Carcharhinus acronotus*), spinner shark (*C. brevipinna*), dusky shark (*C. obscurus*), and, to a lesser extent, blacktip shark (*C. limbatus*), sandbar shark (*C. plumbeus*) and scalloped hammerhead shark (*S. lewini*). Most neonate (newborn) sharks were found in June and July (Beresoff et al. 1997; Thorpe et al. 2003).

Most ocean spawning activity by estuarine dependent species occurs beyond state waters during the winter months. However, eggs and larvae are carried in the water column by currents through nearshore state waters and inlets to estuarine nursery areas. Important spawning aggregations of summer flounder occur on Wimble, Platt, and Kinnekeet shoals off the Outer Banks, in state and federal waters from November to March, peaking near January in North Carolina (MAFMC 1998). Locations of summer flounder spawning aggregations are linked to environmental conditions, such as water temperature and wind direction, and are generally concentrated north of Cape Hatteras, but extend to Cape Lookout.

Nursery

Shallow soft bottom habitat, usually adjacent to wetlands, is utilized as a nursery for many species of juvenile fish. The shallow unvegetated bottom provides an abundance of food and is inaccessible to larger predators. Shallow unvegetated flats have been documented as being particularly important nursery habitats for juvenile summer and southern flounder (Burke et al. 1991, Walsh et al. 1999). A partial list of species that use soft bottom habitat as a nursery area are included in Table 6-2. Studies and ongoing DMF juvenile fish monitoring have found that shallow unvegetated bottom supports high abundances of juvenile fish, composed of relatively few species but which have similar life histories and feeding patterns (Ross and Epperly 1985).

The dominant juvenile species utilizing shallow soft bottom estuarine nursery areas are estuarine dependent winter spawners. Most of the species spawn offshore during the winter. The larvae are transported through inlets into estuarine waters. For many species, the uppermost area of shallow creek systems corresponds to where larval settlement of winter spawned species occurs – the primary nursery areas (Weinstein 1979; Ross and Epperly 1985). However, in tributaries on the western side of Pamlico Sound, such as Neuse, Pamlico, Bay and Pungo rivers, larval settlement tends to occur in lower portions of the creeks (Map 2-4 a-b in Chapter 2). Unlike larval settlement in areas south of Pamlico Sound, salinity is low in the upper reaches of the Sound's tributaries and this may deter larval settlement in those areas. Abundance of juvenile species in estuarine nursery areas peaks between April and July and is correlated with water temperatures (Ross and Epperly 1985). As fish grow, they move to deeper waters and areas lower in the estuary.

Analysis of fishery-independent trawl sampling data, from shallow creeks and bays in Pamlico Sound tributaries, found 78 different fish and invertebrate species over a two-year period (Ross and Epperly 1985). Eight species comprised more than 97% of the total fish abundance. Data from DMF's ongoing juvenile fish monitoring program, which began in 1971, show that the same eight species continue to dominate North Carolina's estuaries (Ross and Epperly 1985). This long-term database provides fishery independent information on species composition and abundance to identify primary and secondary nursery areas. From 1990 to 2003, the eight species that were the most abundant in both the northern and southern sampling sites were:

- spot
- pinfish
- brown shrimp
- Atlantic croaker
- bay anchovy

- blue crab
- silver perch
- Atlantic menhaden

In addition, southern flounder and white shrimp were among the most abundant species sampled in the northern and southern areas, respectively. From 1990 to 2003, a total of 178 species was collected and identified from the juvenile fish monitoring stations throughout the coast (DMF, unpub. data). Because sampling is not conducted year-round, it is probable that this figure underestimates the true number of species present. The annual number of species has ranged from 49 to 83 species per year north of Cape Lookout, and from 45 to 60 species per year south of Cape Lookout (DMF, unpub. data). The consistent abundance of several species over time is an indication that these areas continue to function as healthy nurseries. *Temporal and spatial expansion of juvenile fish sampling would provide additional information on trends in juvenile fish utilization of soft bottom and other habitats, especially summer and fall spawning species, which are generally not present at existing sampling stations during May and June.*

Statistical analyses of DMF's juvenile fish data in the Pamlico Sound system identified specific fish groupings or associations (Ross and Epperly 1985; Noble and Monroe 1991). From the latter analysis, four geographically distinct groupings of juvenile fish species occur in the Pamlico estuarine system (Table 6.3). Menhaden and spot were omitted from the analysis because they were so abundant in all areas that they masked other species abundance trends. Group 1 occurred in the Pamlico, Pungo, Neuse rivers, and along eastern Albemarle Sound. Group 2 occurred in the western bays of Pamlico Sound. Group 3 was located in the shallow area behind the Outer and Core banks, from Oregon Inlet south to Cape Lookout. Group 4 was located along the western shore and tributaries of Core Sound (Table 6.3). Fish groupings in Pamlico Sound appeared to be affected by Bluff Shoal, which runs across the sound in a southeast-northwest direction from around Ocracoke Inlet north to Bluff Point. Bluff Shoal effectively separates Pamlico Sound into distinct basins of differing depth and sediment composition and alters larval settlement patterns into the sound. Distinct fish species groupings are found north and south of the shoal (Ross and Epperly 1985). Salinity was the most important abiotic variable affecting species composition (Noble and Monroe 1991). Groups 1, 2, and 4 occurred where the bottom consisted primarily of shallow unvegetated sediment, while group 3 occurred in SAV beds.

Table 6.3. Dominant juvenile fish species groupings found in the Pamlico Sound system by biotic cluster analysis of juvenile fish data (Noble and Monroe 1991).

Group	Location	Dominant fish species	Primary Habitat
1	Pamlico, Pungo, Neuse rivers, eastern Albemarle Sound	Atlantic croaker, brown shrimp, blue crab, southern flounder	Shallow unvegetated sediment
2	Western bays of Pamlico Sound	Species above + weakfish, spotted seatrout, silver perch	Shallow unvegetated sediment
3	Behind the Outer and Core banks	Pinfish, pink shrimp, black sea bass, gag, pigfish, red drum	SAV beds
4	Western shore and tributaries of Core Sound	Summer and southern flounder, brown shrimp	Shallow unvegetated sediment

In the southern portion of the coast, DMF biologists have found that juvenile fish tend to be most abundant in shallow waters with unvegetated muddy sediment (J. Schoolfield, DMF, pers. com., 2003). The dominant, demersal, juvenile species in coastal waters south of the Pamlico system were also found behind Core Banks and the Outer Banks. Although black sea bass and gag are not very common, brown shrimp, white shrimp, striped mullet, spot and menhaden are more common in the southern estuaries (R. Carpenter, DMF, pers. com., 2003).

Many areas used as nurseries by estuarine dependent fish have been designated as Primary or Secondary Nursery Areas by MFC (Maps 4.8-4.10 in Chapter 4). However, there are other areas of soft bottom that function as nurseries but are undesignated. Benthic anadromous fish, such as Atlantic and shortnose sturgeon, use freshwater soft bottom as a nursery. *The specific locations of anadromous fish spawning areas need to be designated by MFC and adequately protected.* Nearshore ocean subtidal bottom is also a nursery area for summer flounder and shark species. The primary nursery grounds for coastal shark species is in the vicinity of where pupping occurs. Small coastal sharks that use this habitat for a nursery area include spinner (*C. brevipinna*), blacknose (*C. acronotus*), and dusky (*C. obscurus*) sharks (Thorpe et al. 2003; Beresoff et al. 1997). Juvenile Atlantic sturgeon and spiny dogfish, both demersal feeders with overfished fishery status, have been documented over nearshore subtidal bottom between Oregon Inlet and Kitty Hawk during winter months (Cooperative Striped Bass Tagging Program, unpub. data). Subtidal bottom, particularly the surf zone, is also a nursery area for Florida pompano, southern and gulf kingfish (Hackney et al. 1996).

Refuge

Soft bottom habitat can provide refuge to some organisms in some locations through predator exclusion. Shallow, intertidal flats may be inaccessible to large fish predators and therefore protect small and juvenile fish and invertebrates (Peterson and Peterson 1979; Ross and Epperly 1985). Consequently juvenile fish recruit into the shallowest portions of the estuary first. Many invertebrates, including hard clams, can avoid predation by burrowing into the sediment (Luettich et al. 1999). Flatfish, such as flounder and rays, and other small cryptic fish like gobies, can bury slightly into the sediment, camouflaging themselves from predators (Peterson and Peterson 1979). Nonetheless, soft bottom habitat in deep water is a vulnerable place for small fish and invertebrates that cannot burrow. For example, flounders also camouflage themselves in the sediment to ambush prey (Walsh et al. 1999). Because of this, many fish in subtidal water will venture out to feed on the open bottom only at night (Summerson and Peterson 1984).

Corridor and connectivity

Freshwater and estuarine soft bottom channels are the highways for migrating adult demersal fish species to and from other estuarine habitats and the ocean. Demersal feeding anadromous fish, such as sturgeon and striped bass, require a corridor of soft bottom to reach upstream spawning areas. Inlets act as conduits for exchange of sediment, water, and marine organisms between the estuaries and the ocean. Because large fish are less likely to be consumed as prey, they can travel relatively safely over less turbid sand flats and in channels of the middle and lower estuaries (Walsh et al. 1999). Smaller flatfish tend to be more abundant in the shallower uppermost portion of the estuary, where salinities are low, turbidity high, and sediments muddy with high detritus content (Walsh 1999).

While connectivity among structured habitat patches, such as SAV, wetlands, and shell bottom, facilitates movement of blue crabs and other mobile predators through an estuary, a few meters of unvegetated bottom can act as a barrier to movement (Micheli and Peterson 1999). Such barriers can be beneficial to small invertebrates by potentially obstructing predator dispersal and reducing predation risk. Small crabs, gastropods, and infaunal bivalves, such as hard clams, were more abundant, denser, and had higher survival rates on isolated oyster beds (at least 10-15 m of unvegetated bottom between habitats) than on oyster beds adjacent to salt marsh or SAV (Micheli and Peterson 1999). Blue crab predation on infaunal bivalves was greater along vegetated edges of salt marshes and seagrass beds than in unvegetated intertidal flats (Micheli and Peterson 1999). Although structural habitat separations by unvegetated soft bottom may benefit the survival or viability of infaunal populations, fish and crustacean productivity may be enhanced by connectivity of structured estuarine habitats (Micheli and Peterson 1999). These habitat-mediated predator/prey interactions point out the importance of maintaining the integrity of an entire estuarine system.

6.3 STATUS AND TRENDS

Status of soft bottom habitat

Since standardized or comprehensive baseline mapping of soft bottom habitat has not been completed, and because sediments shift and move over time, it is currently not possible to quantify how the extent and condition of the habitat has changed through time. The loss of more structured habitat, such as SAV and shell bottom, has undoubtedly led to gains in soft bottom habitat, but the low quality of areas gained may not be considered beneficial to the ecosystem as a whole. The general type and condition of shorelines in the Albemarle-Pamlico region and Bogue Sound, as well as the rough location of eroding and stabilized shorelines in these areas were summarized by Riggs (2001). The primary alterations to soft bottom habitat are associated with dredging for navigational channels and marina basins. Refer to the threats section for more information.

Status of associated fishery stocks

Fishery independent monitoring programs

The DMF began a juvenile fish monitoring program (Estuarine Trawl Survey) in 1971. This long-term database provides fishery independent (data gathered independent of the fishery) information on species composition and abundance to identify primary and secondary nursery areas, shallow soft bottom habitat usually surrounded by wetlands. The Pamlico Sound Survey is another long-term monitoring program used to calculate juvenile abundance indices in Pamlico Sound and the lower portion of the Pamlico and Neuse estuaries. Data from this survey are compared to results from the Estuarine Trawl Survey and are also used as an indicator of young of year class strength. Juvenile abundance indices (JAI) are calculated from these sampling programs for major fish and invertebrates. The JAI is the annual geometric mean (weighted by strata) of the number of individuals per tow for young of the year fish or invertebrates. The JAI is considered an accurate indicator of recruitment and year class strength for many species, including southern flounder (DMF 2003). The information is used to determine stock status of fishery species by various fishery management agencies. Juvenile abundance indices are also used as a criterion to qualify an area as a designated Primary or Secondary Nursery Area. Designated areas are monitored regularly to provide long-term information on status and trends in recruitment of the dominant estuarine dependent species. Both surveys are critical components to stock assessments since they are independent of commercial or recreational fisheries (DMF 2003). Trends in juvenile abundance indices may indicate change in the habitat conditions (DMF 2003). However, consistent and comparable JAI data are only available to about 1990 and, prior to this time, considerable habitat losses and changes occurred.

Flatfish are closely linked to soft bottom habitat and juvenile abundance indices from the Estuarine Trawl Survey for southern flounder and hogchoker are shown in Figure 6.1. Southern flounder is a commercially and recreationally important fishery species, while hogchoker is a non-fishery species found in northern and southern estuaries of the state. The JAIs for both species have followed similar temporal patterns, varying between 0.5 to 2.5. Both species had peak JAIs in 1996. JAI of southern flounder experienced large declines in 1997, 1998 and 2002; notably, a 16.7% decline was recorded between 2001 and 2002. The 2002 stock status report stated that the estimated population biomass of this species had declined by 32% over the past decade (DMF 2003). Hogchoker JAI also declined to low levels in 1998, showed some improvement in 1999, but has remained relatively low since 2000. These results indicate that recruitment of both fishery and non-fishery flatfish species has been variable over time and strongly influences annual JAIs. However, hogchoker has exhibited greater recovery following years with low JAIs than southern flounder. Both species have exhibited relatively low JAIs since 1996.

Trends in JAI of Atlantic croaker from both the Estuarine Trawl Survey and the Pamlico Sound Survey are very similar (Figure 6.2). Atlantic croaker is a benthic feeding fish that could be affected by changes in soft bottom habitat, such as reductions in benthic food sources due to toxicity or anoxia in sediments. Annual trends in juvenile abundance of both surveys are very similar. Sizes of fish collected in the

Pamlico Sound Survey were larger, accurately reflecting that juvenile fish first settle in the primary nursery areas and later move into the sound. Both juvenile abundance indices for Atlantic croaker experienced large fluctuations and are currently near their lowest recorded levels in the past 12 years. According to the DMF 2002 stock status report, there are some signs of recovery, such as increased commercial CPUE, increased landing size, and improved age structure (multiple year classes), but JAIs remain below average and landings in estuarine waters have not returned to historical levels. An ASMFC FMP was created in 1987 and was reviewed most recently in 1998. Research needs, including a coastwide stock assessment, have been completed and are being reviewed by ASMFC. The stock assessment determined that Atlantic croaker is a recruitment-driven stock, where biomass and landings fluctuate in response to large year classes.

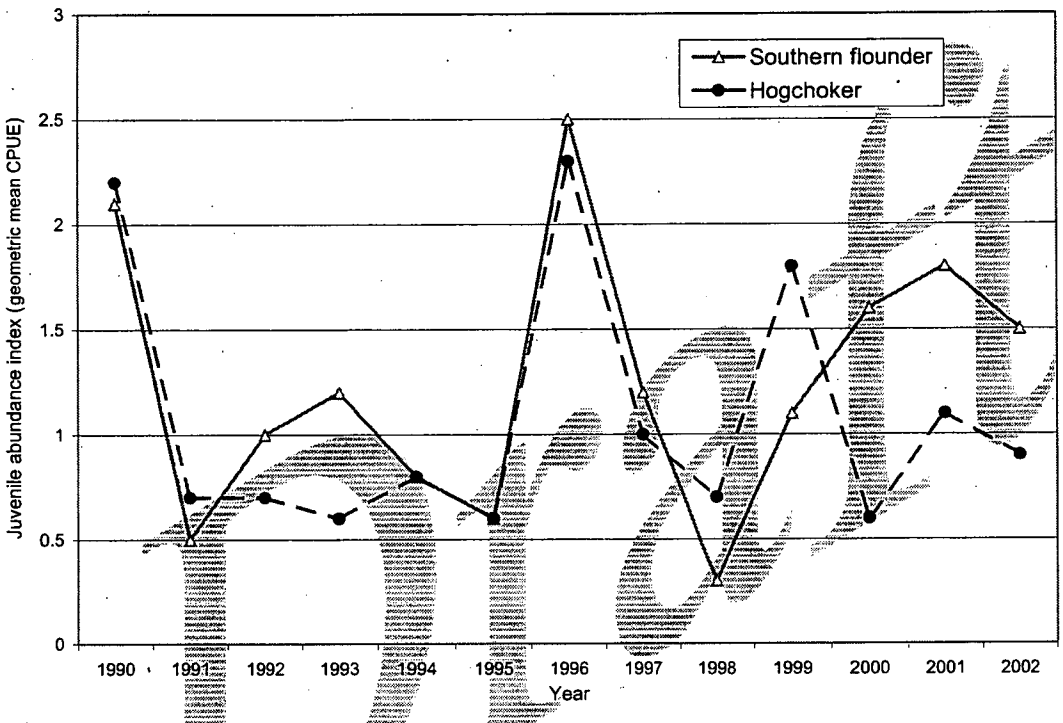

Figure 6.1. Southern flounder and hogchoker juvenile abundance indices (geometric mean CPUE) from two DMF juvenile fish sampling programs, core stations sampled in May and June for each program pooled - the Estuarine Trawl Survey and the Pamlico Sound Survey, 1990-2002.

Hard clams, although also present in shell bottom and SAV habitats, require soft bottom habitat for burrowing. Because clams remain fairly stationary and are filter feeders, they may be vulnerable to habitat degradation, such as sediment contamination or sedimentation. The status of the hard clam stock is currently unknown due to lack of adequate data (DMF 2001). However, using trip ticket data, DMF (2001) concluded that hand harvest of clams appeared to be stable, but that clam abundance, in areas where mechanical clam harvest occurred, appeared to decline from 1994 to 1999. MFC recommended that mechanical harvest limits in Core Sound be further restricted. *Reducing the area available to mechanical clam harvesting is another means of protecting clam stocks and would also provide additional habitat protection.*

Twelve of 18 soft bottom associated fishery species (bolded species in Table 6.2) were evaluated by DMF for stock status in 2002. Of these twelve species, two (17%) were of unknown status. Of the ten stocks

whose status is known, three (30%) were classified as Viable, one (10%) was Recovering, two (20%) were of Concern, and four (40%) were Overfished (Table 6.2, Figure 6.3). Viable species included shrimp, spot, and summer flounder; red drum was a Recovering species. Overfished species included Atlantic and shortnose sturgeons, southern flounder, and coastal sharks. The species listed as Concern include striped mullet and Atlantic croaker.

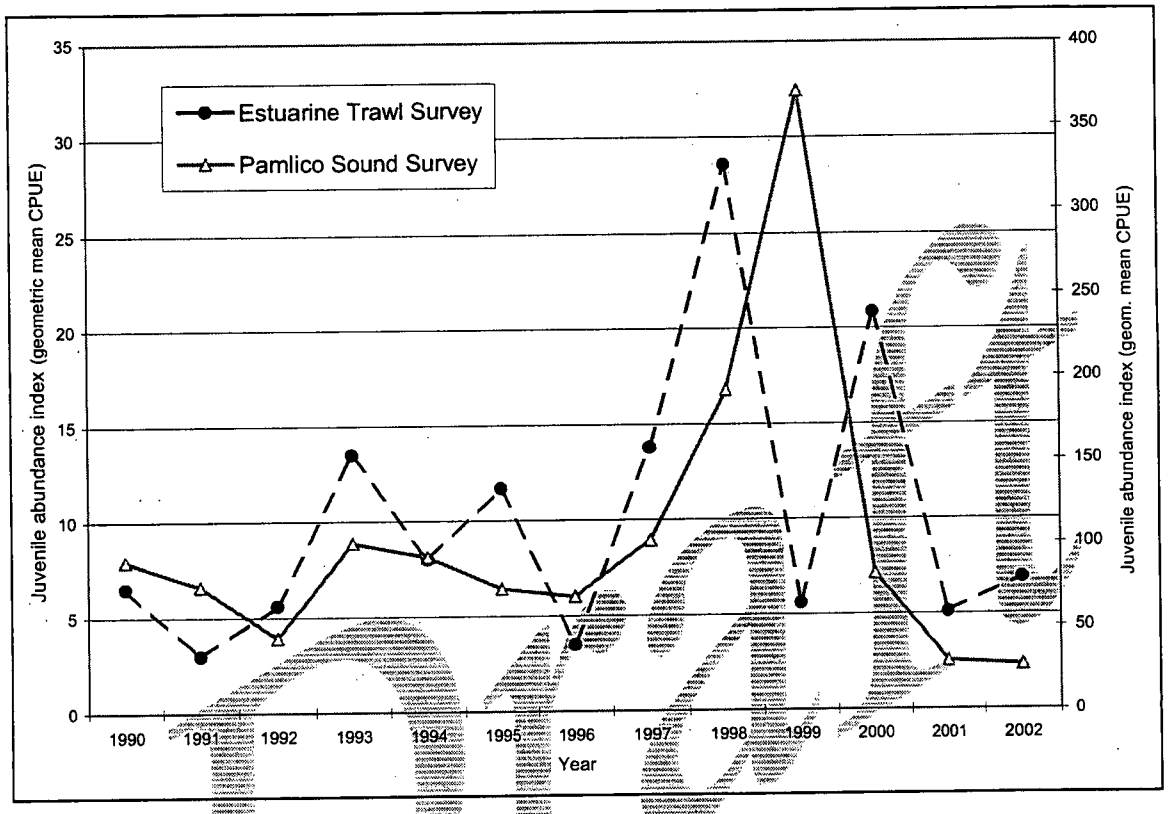

Figure 6.2. Atlantic croaker juvenile abundance indices (geometric mean CPUE) from two DMF juvenile fish sampling programs, core stations sampled in May and June for each program pooled - the Estuarine Trawl Survey and the Pamlico Sound Survey, 1990-2002.

Both sturgeons historically supported a valuable commercial fishery, however landings declined dramatically by the early 1900s. Shortnose sturgeon is currently a federally listed endangered species and Atlantic sturgeon is considered threatened in North Carolina (Ross et al. 1988). Atlantic and shortnose sturgeon have not shown signs of recovery despite a fishing moratorium in North Carolina since 1991, indicating that habitat and water quality issues are also affecting recovery. Potential habitat issues could include reduction of benthic food sources in fresh water due to eutrophication or toxin contamination or degradation of spawning and nursery habitat from channel obstructions, channelization, and sedimentation.

Coastal shark species, such as sand bar sharks, Atlantic blacktips, Atlantic sharpnose, hammerheads and duskys, are slow growing and mature late, making them more vulnerable to overfishing. Federal and state harvest restrictions have been in place since 1993, but there has not been evidence of recovery. Degradation of nearshore marine bottom from beach nourishment or nonpoint runoff could potentially impact pupping and nursery areas.

The overfished status of southern flounder is due in part to overfishing but may also be related to habitat

issues in the low salinity estuaries. Severe hypoxic events and anoxia can directly affect populations of southern flounder through mortality from suffocation and indirectly from reduced growth rates, loss of preferred prey (mortality of benthic community), changes in activity patterns, or disease. The Division is currently working on a Fishery Management Plan for southern flounder.

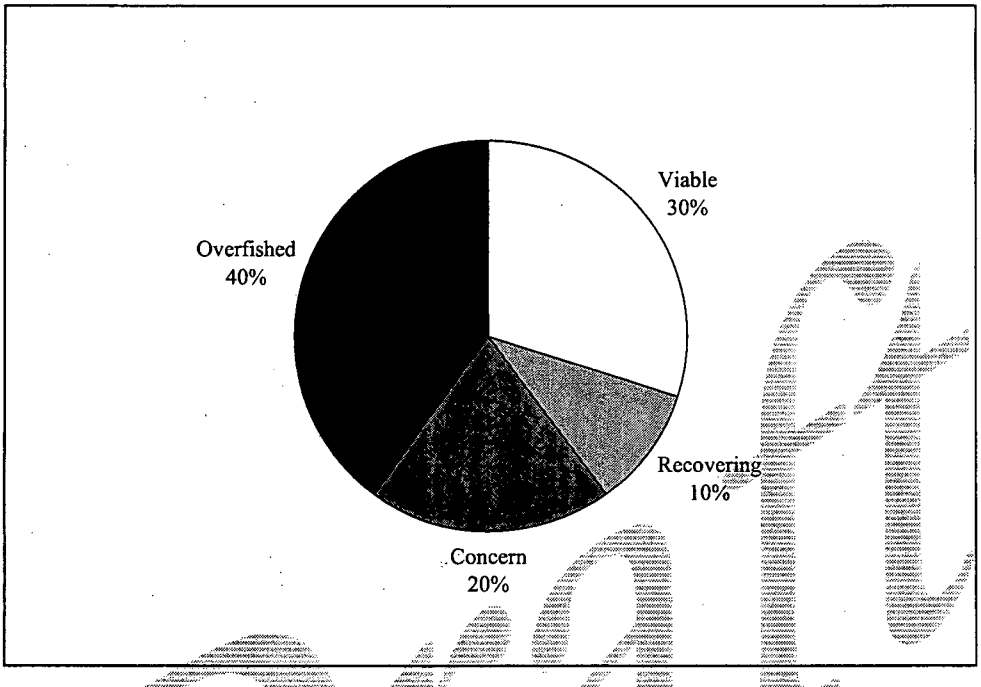

Figure 6.3. Percent of soft bottom dependent fishery species classified as overfished, concern, or viable in the DMF 2003 stock status report, N = 10 (DMF 2003). (refer to Table 6.2 for list of fishery species).

Striped mullet are of concern primarily due to an increase in associated fishing effort. A juvenile abundance index is currently not available for striped mullet and more biological information is needed to determine habitat threats. The Division is currently working on a Fishery Management Plan for striped mullet. Atlantic croaker is listed as concern because JAIs and estuarine landings have remained low. *All three commissions should work together to address habitat issues that will protect or enhance southern flounder, sturgeon, and shark habitat.*

From 1968 to 1981, monthly fish surveys by DMF were conducted in coastal ocean waters but have since been discontinued. Currently in coastal waters of North Carolina, fishery-independent data are available from shallow water trawl surveys conducted by the Southeast Area Monitoring and Assessment Program – South Atlantic (SEAMAP-SA). SEAMAP is a cooperative state/federal/university program that was first implemented in the southeastern United States in 1983 and is coordinated by ASMFC. SEAMAP currently provides the only region-wide standardized surveys for monitoring long-term status and trends of demersal fish and invertebrate populations that utilize marine soft bottoms as well as other habitats. The SEAMAP study area includes inner (4m depth contour) and outer (10m depth contour) strata stations in Long Bay, Onslow Bay, and Raleigh Bay in North Carolina.

Since 1990, 141 species were found in all three bays. Many of the dominant species are also dominant in estuarine waters. In examining data from 1990 to 2000, spot and Atlantic croaker consistently comprised a large portion of the catch in all bays and years. Spot is generally most abundant in Long Bay and accounted for 20 to 50% of the catch in most years in the three bays. Other abundant species included

striped anchovy, squid, pinfish, and porgies.

Since 1990, species diversity from the shallow (approximately 4m) strata sampling sites has been highest in Long Bay (124 – 147 species) and lowest in Raleigh Bay (81 – 104 species). The total number of species collected in each bay has only fluctuated slightly from year to year, and appears fairly stable over time. Densities in Long Bay ranged from 212 individuals/hectare (ind./ha) in 1993 and 2000 to 511 ind./ha in 1991. Long Bay and Onslow Bay had very similar densities of fish and fluctuations in abundance. Fluctuations in fish density among years were greatest in Raleigh Bay. These data indicate strong inter-annual variation in year class abundance but demonstrate no clear trends.

Trends in annual catch per tow, or CPUE, of demersal species from SEAMAP data are an indicator of relative abundance of late juvenile and adult species. Annual trends in catch per tow for summer and southern flounder, striped anchovy and southern kingfish were examined since the flounders are strongly associated with estuarine and marine soft bottom and latter two species are common in the surf zone and nearshore waters. Of these four species, SEAMAP bottom trawl data indicate a decline in abundance only for southern flounder (Figure 6.4). Southern flounder CPUE has shown a general decline since its peak abundance from about eight fish/tow in 1992 to two fish/tow in 2002. Southern flounder spend more time in low salinity estuarine waters than summer flounder, and therefore may be more affected by estuarine habitat and water quality changes. The decline noted in southern flounder CPUE is consistent with DMF's stock status for this species. While DMF's stock status report indicates that the decline in population biomass is primarily due to overfishing (DMF 2003), habitat degradation, such as toxin contamination of bottom sediments or bottom anoxia and benthic kills, could add additional stress to the species, delaying recovery.

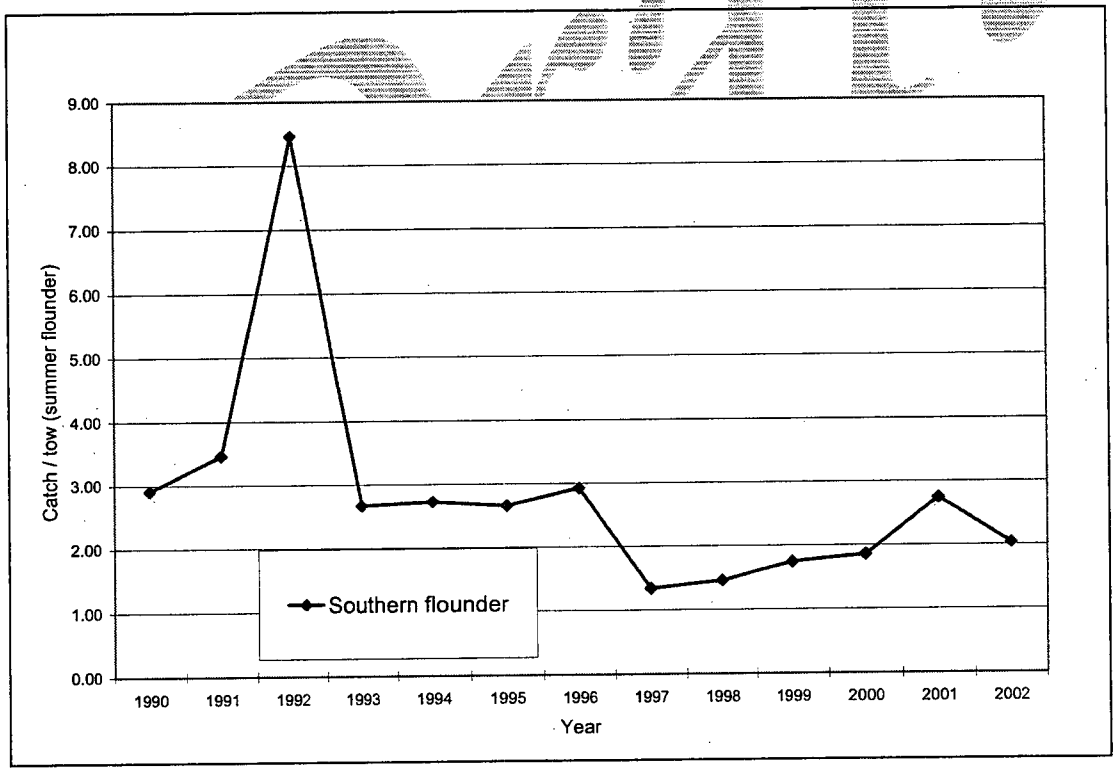

Figure 6.4. Annual CPUE of southern flounder collected in nearshore coastal ocean waters, by fishery independent SEAMAP-SA trawl surveys, 1990-2002

Designated areas

There have been some federal actions taken to designate and protect certain portions of soft bottom habitat in coastal ocean waters. The SAFMC designated all coastal inlets as Habitat Areas of Particular Concern (HAPC) for blue crab, estuarine-dependent snapper-grouper species, penaeid shrimp, and red drum. The sandy shoals of Cape Hatteras, Cape Lookout, and Cape Fear are designated as HAPC for all coastal migratory pelagics, including king mackerel, Spanish mackerel, dolphin, and cobia. In May 2000, Presidential Executive Order 13158, Marine Protected Areas, was implemented. The order mandated strengthening of the management, protection, and conservation of existing marine protected areas and establishing or expanding additional marine protected areas. Marine protected areas (MPA) were defined as "any area of the marine environment that has been reserved by Federal, State, territorial, tribal, or local laws or regulations to provide lasting protection for part or all of the natural and cultural resources therein" (Federal Register 2000). Among the many agencies cited in the order, Environmental Protection Agency (EPA), relying on existing Clean Water Act authorities, is required to identify and prioritize natural and cultural resources for additional protection, propose science-based protocols for monitoring and evaluating marine protected areas, and propose science-based regulations to ensure appropriate protection of habitat and water quality standards. These actions may provide additional protection for North Carolina's marine soft bottom habitat, as well as hard bottom and other ocean habitats. State agencies are in the process of compiling an inventory of existing marine managed areas prior to assessing the need and feasibility of establishing new MPAs in North Carolina.

6.4 THREATS AND MANAGEMENT NEEDS

Physical threats

Of the coastal habitats in North Carolina, soft bottom is probably the most resilient to physical alterations because of its lack of structure and dynamic nature. However, because this habitat plays a vital role as nursery and foraging grounds for fish and invertebrate species, it is important that threats to soft bottom are identified and addressed. Human activities that can physically impact soft bottom habitat include dredge and fill activities, marinas and docks, shoreline stabilization, and use of bottom disturbing fishing gear.

Dredging

There are physical and biological impacts to the soft bottom communities from dredging activities. New or maintenance dredging for navigational channels or marina construction alters topographic and hydrologic features that attract fish for feeding, refuge, or spawning, and modifies sediment grain characteristics (SAFMC 1998). Dredging removes all benthic infauna from the affected areas immediately, reducing food availability temporarily to numerous fish and crustaceans, including southern and gulf kingfish, Florida pompano, spot, Atlantic croaker, flounder, and shrimp (Hackney et al. 1996; Peterson et al. 2000a). Whether the magnitude of prey reduction limits fish growth, reproduction or survival depends on the species' diet preference, foraging range, mobility, abundance of prey elsewhere, and extent and location of other benthic disturbing activities. In the case of shortnose and Atlantic sturgeon in the Cape Fear river system, dredging for the Wilmington Harbor appeared to disrupt spawning migrations (Moser and Ross 1995). Inlet dredging in winter can kill or displace female blue crabs that are burrowing in the inlet sediments. Disturbance associated with inlet dredging can also deter or alter summer spawning activity of red drum, weakfish, spotted seatrout, silver perch, and blue crab (Luczkovich et al. 1999; DMF 2000). Spawning activity around the inlets occurs from May through October, depending on the species (refer to spawning table in the Water Column section). Because spawning activity occurs at night, daytime dredging may not be a problem. However, there are also possible indirect effects associated with dredging, such as reductions in benthic prey availability and alterations of the acoustic environment (J. Luczkovich, ECU, pers. com., 2003).

Impacts in the water column associated with dredging induced turbidity were discussed in the water

column section of the plan. Turbidity, however, also affects benthic invertebrates in the soft bottom. For example, mole crabs were killed by excess turbidity generated during a beach nourishment project in Atlantic Beach (Reilly and Bellis 1983). Growth of coquina clams was significantly reduced when exposed to elevated turbidity (Lindquist and Manning 2001). The invertebrates and fish associated with inlet subtidal bottoms, tidal deltas, meandering channels and shallow shoals have adapted to that specific environment and to its natural disturbance regimes. *More research is needed to assess direct and indirect dredging impacts on blue crabs and inlet spawning species.*

Map 3.14 a-c depicts the location of the major navigational channels in North Carolina's coastal waters. Soft bottom habitat in the southern portion of the coast has been highly modified by navigational dredging and associated spoil islands. As noted earlier under ecological role and functions, shallow unvegetated bottom is an important nursery and foraging area for many species. Converting shallow bottom into deeper basins and channels can reduce primary and secondary productivity of the bottom (Wendt et al. 1990). *Commenting and permitting agencies should use their existing authorities to 1) minimize new dredging of shallow soft bottom habitat, b) prevent direct impacts from dredge and fill projects, and c) limit as much as possible indirect impacts to shallow soft bottom or other habitats.*

Log salvage is another form of dredging that causes disturbance of soft bottom and water column habitat. However the magnitude of disturbance is much less than that created by dredging of a permanent channel or basin. Refer to the water column section for more information on this activity.

Mining

Mining or mineral extraction is another dredging activity that has potential habitat impacts. Phosphate deposits, of sufficient quality and quantity to be potentially exploitable, have been identified within the Pungo River geological formation in Onslow Bay (Map 6-4). The formation occurs beneath the Pamlico River and also extends beneath ocean soft bottom from Bogue Banks southwest to Frying Pan Shoals, is approximately 150 km long, 40 km wide, and covers approximately 6,000 km^2 (Powers et al. 1990). The largest deposit occurs at Frying Pan Shoals, seaward of state jurisdiction, and is potentially available to dredge mining. Other phosphate deposits, referred to as the Northeast Onslow Bay phosphate district, occur immediately off Bogue Banks within and seaward of state jurisdiction. Because of its proximity to shore and a deep-water port, the economic potential of mining these deposits is high. In addition, other minerals occur in offshore sediments (as phosphate mining byproducts) including trace elements, radioactive substances like uranium and phosphogypsum, heavy minerals such as titanium, zirconium, aluminosilicates, and valuable metals such as gold and silver (Riggs and Manheim 1988). Currently no mining is ongoing in North Carolina waters, although potential exists. Continued cooperation between COE, DWQ 401 staff, CAMA, and others responsible for review of mining projects is necessary to protect and mitigate against soft bottom and other habitat impacts.

Dredge material disposal on subtidal bottom

Deposition of dredge material from navigational channel maintenance on estuarine or coastal dredge disposal sites, ebb tidal deltas, or other areas of subtidal bottom results in increased turbidity, temporary reduction in and slow recovery of the abundance and diversity of benthic invertebrates (SAFMC 1998). In estuarine waters, dredge material islands, also referred to as spoil islands, were often created adjacent to the dredged navigational channels. Subsequent maintenance dredging deposits new material onto these islands. The majority of the dredge material islands were created when the ICW was first created in the 1930s. The creation of permanent dredge islands a) reduced the amount of available underwater habitat (including soft bottom) , b) changed the natural hydrology of the surrounding waterbodies, and c) had a relatively more profound effect on the smaller waterbodies of the southern coast. However, the islands can provide beneficial nesting bird habitat and fringing wetland habitat along the perimeter. *A state policy on dredge material management, that minimizes impacts to coastal fish habitat, including soft bottom habitat, should be developed.*

In ocean waters, dredge disposal occurs in both offshore designated disposal sites and in nearshore waters and ebb tide deltas. Offshore sites are in federal waters in depths greater than 30 ft, whereas nearshore areas are in state waters in depths less than 30 ft deep. Sediment deposited in nearshore waters and on ebb tide deltas are incorporated into the beach profile and are discussed further in the beach nourishment section. The rate of bottom recovery will depend on the volume discharged, characteristics and similarity of the dredge material, hydrography of the disposal area, time of year, and the resulting turbidity (Windom 1976; SAFMC 1998). Disposed dredge material that contains elevated levels of toxic contaminants may have adverse impacts on the benthic community. There are two EPA approved and designated ocean dredge material disposal sites off North Carolina, one off Beaufort Inlet and one off Cape Fear River Inlet. Both are located just seaward of the state territorial seas.

Marinas and docks

Soft bottom habitat may be affected by marina and dock facilities through alteration of the shoreline configuration, circulation patterns, and subsequently, changes in bottom sediment characteristics (Wendt et al. 1990). Because benthic microalgae, an important component of primary production in soft bottom habitat, are light dependent, bottom sediments in dredged marinas will have reduced light availability due to the deeper water depth and shading from docking structures. There are few studies that examine the effect of marinas and boating activity on benthic productivity. A study estimating macroalgae and microalgae productivity before and after construction of a marina in Long Island Sound found that microalgae production on soft bottom would decline by 48% post construction and macroalgae production would decline by 17%, due to changes in depth, light, and hard structures (Ianuzzi et al. 1996). However, the authors concluded that some of this loss would be offset by additional microalgal production on hard structures in the marina.

Operation of a marina can also affect productivity of the soft bottom community due to introduction of heavy metals, hydrocarbons, and bacteria (Chmura and Ross 1978; Marcus and Stokes 1985; Voudrias and Smith 1986). In a South Carolina estuary, distinct differences were found in the benthic community at a marina compared to the control site (Wendt et al. 1990). The marina appeared to favor the occurrence of infaunal burrowers over infaunal tube dwellers. Overall, there was greater abundance of deposit feeders at the marina. The authors concluded that the presence of docks and pilings may have resulted in greater habitat complexity and therefore greater diversity of sessile and motile epifauna. However, the study did find a lower abundance of several pollution sensitive species at the marina, indicating some environmental degradation, which could affect the food chain. Faunal differences were attributed to the finer grained sediments occurring in the marina and proximity to hard structures.

While the higher concentration of organic matter contributed to a greater abundance of certain deposit feeders, certain species were excluded from the marina. While the additional colonization of non-mobile epifauna on dock structures within the marina may provide additional biotic diversity and a food source for some fish, high densities of fouling organisms (tunicates, barnacles, bryozoans) in marinas can reduce dissolved oxygen levels due to high respiration rates (Wendt et al. 1990). Toxic substances in fouling organisms bioaccumulate and can become concentrated in successively higher levels of the aquatic food chain (Nixon et al. 1973; Marcus and Stokes 1985). Both PAHs and heavy metals were found to be significantly higher in bottom sediments in the marina compared to the control site. Heavy metals and hydrocarbons are toxic to many soft bottom dwelling invertebrates and benthic feeding fish (Weis and Weis 1989). The effect of toxins from marinas or other sources is discussed in more detail in the toxins section. *Stringent efforts are needed to prevent toxic contamination of sediments from marinas to reduce impacts to soft bottom productivity. Toxic sources at marinas should also be addressed.*

In another study in South Carolina, differences in the benthic community in areas with no, low, and high densities of docks were examined. Similar to the other South Carolina study, some pollution sensitive species of polychaetes were more abundant at control sites than high dock sites (Sanger and Holland

2002). Areas in the high dock category usually had the lowest values of benthic abundance. Three species (*S. benedicti, T. acutus, P. cornuta*), and the total number of organisms had a significant correlation to docks, with the abundance of organisms decreasing as the number of docks increased (Sanger and Holland 2002). Total fish and crustacean abundance, including bay anchovy, silver perch, spot, and brown shrimp, was highest in the no dock category, but was not significantly correlated with dock number (Sanger and Holland 2002). This study also found that shading from docks decreased stem density of *Spartina alterniflora* by 70%, which was comparable to other studies in Virginia and other areas of the United States. This reduction can lower the overall productivity in the vicinity of marinas and multi-docking facilities. Overall productivity in a marina can also be reduced by effects on associated wetland and shell bottom communities. Refer to these sections for more information related to marina and dock impacts.

Several studies indicate that marinas and concentrations of individual docks have potential to alter soft bottom habitat, particularly shallow water habitat, in ways that can reduce productivity of the system as a whole. Marina siting issues were discussed in the earlier water column section, and the location of marinas in North Carolina was shown in Map 2.14 a-c. The majority of docking facility permits are for individual piers. The number of individual pier permits issued annually by the CRC, with the exception of 2001, has continually increased in the coastal counties through 2000 (Figure 2.9, water column section). Since then, the number of permits issued annually has dropped below 1999 levels to around 800 per year. The DCM estimates that approximately 10% of these piers do not have boats associated with them and are used solely for fishing, swimming, view, etc. The large increase in permit numbers from 1999 to 2000 is at least partially due to large numbers of repair or replacement requests following hurricane damage. If properly designed and located, individual piers do not pose a large threat to soft bottom habitat. However, when docks are permitted in very shallow areas, moored boats or floating docks may actually sit on the bottom for a large portion of a tidal cycle (up to 12 hr) or cause considerable turbidity or prop dredging when attempting to motor to deeper waters (F. Rohde, DMF, pers. com., 2003). Either situation can significantly reduce primary or secondary productivity (F. Rohde, DMF, pers. com., 2003). There is currently no minimum water depth required to receive a dock permit. *Dock siting criteria should include a minimum water depth to prevent boats or floating docks from sitting directly on soft bottom or other benthic habitats.*

Multi-docking facilities (10 slips or less according to the CRC definition) may be a greater threat to soft bottom habitat due to the number of these facilities and their concentration in shallower areas than typical marinas. However, by concentrating boat use, overall impacts may be less than what would be needed to serve the same number of boats with individual piers at individual residences. Also, because boat use is concentrated, other areas of the shoreline, including wetland and shell bottom habitats, may not be impacted by docking related activities. There are about five to eight times more permits issued annually for small multi-docking facilities (non-marinas, 1-10 slips) than marinas (> 10 slips). The annual number of non-marinas has generally increased since 1996 (Figure 2.9- water column section). The annual number of permits issued for new or expanding marinas has remained fairly stable over the past ten years. As waterfront property becomes increasingly developed, requests for new piers and marinas in shallower and less suitable locations will increase. *A comprehensive dock and marina policy is needed to address appropriate design, siting, operation, and maintenance procedure and cumulative impacts to minimize impacts to soft bottom and other fish habitats. Research on the impacts of these parameters is needed.*

Shoreline stabilization

Different shoreline stabilization strategies are effective under different environmental conditions, with varying effects on soft bottom and other habitats. Strategies range from soft techniques such as marsh planting to engineered hard stabilization techniques. Estuarine and ocean shoreline stabilization are discussed separately below.

Estuarine and riverine shoreline stabilization

In North Carolina, estuarine and riverine shoreline stabilization has traditionally utilized hard structures such as bulkheads, rock revetments or riprap, sills, breakwaters, groins, or combinations thereof. Bulkheads are the most commonly used structure. Beach nourishment is generally not utilized. Although excessive sediment loading is considered a water quality issue, erosion of sediments is a natural process that provides sand for maintenance of beaches, wetlands, and shallow water habitat. When this sand supply is cut off by a hard structure under rising sea level conditions, the long-term results are a net loss of beach and intertidal shoreline and the deepening of shallow water habitat. High quality intertidal shoreline and shallow water habitat serve as important nursery, feeding and spawning grounds to many economically and biologically valuable fish species in North Carolina. Multiple studies have shown that the diversity and abundance of invertebrates and juvenile fish are reduced adjacent to bulkheaded areas (Waters and Thomas 2001; Peterson et al. 2000; Byrne 1995; Ellifrit et al. 1972; Gilmore and Trent 1974; Mock 1966; O'Rear 1983). In the 2003 legislative session, House Bill 1028 was approved, which allows the CRC to establish a general permit for construction of offshore parallel rock sills for estuarine shoreline protection. Prior to this, a major permit was required for such activity, while construction of a bulkhead required a general permit. *A comprehensive examination and revision of current CRC shoreline stabilization rules using best scientific information is still needed to minimize impacts from this activity to soft bottom, particularly intertidal estuarine shorelines. Research is needed to determine if and how oyster shell could be utilized as an alternative to rock or wooden stabilization structures to create "living shorelines" that are effective in stabilizing the shoreline while also providing habitat value.* Refer to the wetlands section for additional information of the impact of shoreline stabilization to that habitat.

An additional concern of wooden bulkheads is the toxicity of preserved wood to certain aquatic organisms. Estuarine and riverine bottom may be contaminated by wooden bulkheads treated with copper, chromium, and arsenic (CCA). These elements are leached from CCA treated wood, gradually accumulate in adjacent sediments, and have the capacity to harm marine benthos (Weis and Weis 1994; Weis et al. 1998). The toxicity of these metals to aquatic organisms is well recorded and all three are listed as priority pollutants by the EPA (Hingston et al. 2001). Copper appears to have the most toxic effect on marine organisms and is consistently released in the largest relative amount (Weis and Weis 1994).

Studies have documented significantly elevated concentrations of metals and reduced abundance and diversity of the benthic community extending approximately 30 ft (10 m) from bulkheads treated with CCA, decreasing with distance from the structure (Weis and Weis 1994; Weis et al. 1998). Benthic organisms that were lethally or sublethally impacted included macroalgae, amphipods, polychaetes, oysters, fiddler crabs, sea urchins, mud snails, and fish embryos. Sediment contamination has been documented to be higher in a residental bulkheaded canal than adjacent to bulkheaded open water (Weis and Weis 1995). Concentrations decreased more rapidly with distance from bulkhead in the open water system. Weis et al. (1995) found that oysters living on CCA-treated wood in a residential canal had 15 times more copper (~ 200 µg/g wet weight), two to three times more arsenic, and significantly more degeneration of digestive gland diverticula than compared to that of reference oysters. Copper is known to cause this pathology. Although bioaccumulation has been observed in shellfish and other invertebrates grazing on CCA contaminated algae or bivalves, similar biomagnification in fish has not been documented for these elements (Weis and Weis 1999). The extent of sediment contamination from CCA could be significant, considering the magnitude of preserved timber used in the marine environment for bulkheads and docks (Weis and Weis 1994). Toxicity of wood decreases with time but CCA can continue leaching for many years. In addition, bulkheads need to be replaced periodically, providing a continual source of newly treated wood in coastal waters.

As of January 1, 2004, the EPA will not allow CCA products to be used to treat wood intended for residential uses due to human health concerns, primarily of arsenic, and environmental impacts. Although non-arsenic containing products will be available, these alternatives may also be toxic to marine organisms. Rock sills and revetments are a non-wood alternative that do not require any chemical

preservatives. *Any new wood preservative products should be evaluated for toxicity to marine benthic organisms and juvenile fish. When formulating revisions to CRC's shoreline stabilization regulations and guidelines, CRC should take into account the impact of sediment contamination and potential toxicity of wood preserved bulkheads on marine organisms.*

Oceanfront shoreline hardening

Shoreline hardening, or hard stabilization, involves construction of hard immovable engineered structures, such as seawalls, rock revetments, jetties, and groins. Seawalls and rock revetments run parallel to the beach. Seawalls are vertical structures, constructed parallel to the ocean shoreline and are primarily designed to prevent erosion and other damage due to wave action. Revetments are shoreline structures constructed parallel to the shoreline and generally sloped in such a way as to mimic the natural slope of the shoreline profile and dissipate wave energy as the wave is directed up the slope. Breakwaters are structures constructed waterward of, and usually parallel to, the shoreline. They attempt to break incoming waves before they reach the shoreline, or a facility (e.g., marina) being protected. Jetties and groins are manmade structures constructed perpendicular to the beach, with jetties usually being much longer and located adjacent to inlets. The primary purpose of jetties and groins is to create or widen beaches by capturing sand moving along the shoreline (littoral drift).

It is now well accepted that hard stabilization techniques along high energy ocean shorelines will accelerate erosion in some location along the shore, resulting in the eventual loss of beach and intertidal bottom as well as increased scouring and chronic turbidity in the surf zone (NRC 1995; Peterson et al. 2000a; Walton and Sensabaugh 1979; Pilkey et al. 1998). Recognizing that hardened structures destroy recreational beaches and the intertidal zone, four states have prohibited shoreline armoring: Maine, Rhode Island, South Carolina, and North Carolina (effective in North Carolina since 1985).

Only a relatively small amount of North Carolina's ocean shoreline is hardened compared to other states, having roughly 6% of the developed shoreline hardened (Pilkey et al. 1998). In contrast, South Carolina, Florida (Atlantic coast), and New Jersey have 27%, 45% and 50% of their respective shorelines covered with some form of hard stabilization. Of all hardened structures, seawalls are the greatest threat to beach erosion and degradation of the intertidal beach (Pilkey et al. 1998). Moreover, the areal loss of beach at hardened shorelines is often managed by implementing nourishment projects, possibly having additional damage to subtidal bottom. Jetties, in addition to causing erosion on downdrift beaches and accelerating the need for beach nourishment projects, obstruct fish passage through adjacent inlets (Blanton et al. 1999). Jetties in some locations may therefore be the most directly detrimental shoreline stabilization structure to coastal fish habitat (for more information, refer to water column threats section). In the 2003 legislative session, House Bill 1028 was approved, putting into law the CRC prohibition on construction of permanent erosion control structure on an ocean shoreline. *Prohibition of shoreline hardening of the oceanfront should continue to be enforced for overall protection of barrier island processes, nearshore soft bottom communities, and associated fish species.*

Soft stabilization on oceanfront shorelines

Because hard stabilization is currently prohibited in North Carolina, the only beach stabilization techniques available to local communities are soft techniques, such as beach nourishment and beach bulldozing. Beach nourishment is the introduction of new sand to dry and intertidal beach and adjacent shallow waters from upland areas, navigational channels, inlet systems, or submerged "borrow sites" to restore or enlarge a beach. There are generally two categories of COE projects that result in sand being put on beaches: disposal projects and storm damage reduction projects. Disposal projects are generally much smaller in magnitude than storm damage reduction projects, and can be expected to have a smaller impact on fish habitat. Sand bypassing is a type of disposal project where sand is moved around physical barriers, such as a jetty or deep port, that interrupt the natural littoral drift along the shoreline.

Beach bulldozing, also referred to as beach scraping, is a method of short-term erosion protection that has been used in North Carolina for approximately 40 years. Beach bulldozing is the process of mechanically redistributing beach sand from the lower portion of the intertidal beach to the upper portion of the dry beach to create or enhance the primary dune. In contrast to beach nourishment, new sediment is not added and the existing beach is not widened. Because beach bulldozing only utilizes sand on-site, the impacts of this soft technique are less, relative to those from beach nourishment (Pilkey et al. 1998). *The effectiveness and cumulative impact of this activity should be assessed and appropriate guidelines should be included in a coastal beach management plan.*

Beach nourishment impacts at mining areas / "borrow sites"

Mining is defined under the Mining Act (G.S. 74-48 and G.S. 47-49) as "the breaking of surface soil in order to facilitate or accomplish extraction or removal of mineral, ores, or other solid matter." Whether the purpose is beach nourishment, channel maintenance, or mineral extraction, the consequences of mining activities have similar effects upon the habitat. Dredging of subtidal bottom initially causes mortality of benthic organisms within the dredged area and causes elevated turbidity in an extended area, which may also result in negative impacts. Physical recovery of "borrow sites" in nearshore areas and shoals can be a slow process. Because such sites often refill with finer-grained material than was originally present (NRC 1995; Van Dolah et al. 1998), post-dredging turbidity may remain high indefinitely (Peterson et al. 2000). In South Carolina, refilling of sediment took from two to at least 12.5 years at varying "borrow sites". Since these areas refilled with a more fine-grained, muddy sediment, the sites became unsuitable as future sand sources and altered benthic species recruitment patterns (Van Dolah et al. 1998; Van Dolah et al. 1992). Use of ebb or flood tidal deltas and nearshore sandbars within the active shoreface as a sand source for nourishment projects removes sand from the inlet system, alters the sediment budget, and may result in accelerated erosion from adjacent beaches (Wells and Peterson 1986). Roessler (1998) also suggested that the major cause of beach erosion on Bogue Banks was the removal of sediment from the longshore system due to the intense dredging and deepening of Beaufort Inlet for access to the state port at Morehead City. Sand from that dredging operation has at times been taken out of the inlet, hence out of the longshore system, and disposed of offshore beyond the active beach profile. Biological recovery rates of mined sites vary, but generally are longer than those reported at the intertidal beach disposal sites, and in some cases may be altered indefinitely. Reported recovery rates for mined sites include:

• Van Dolah et al. (1992)	3 – 6 months	South Carolina
• Posey and Alphin (2001)	6 – 18 months	North Carolina
• COE (2001)	18 – 30 months	New Jersey
• NRC (1995)	> 12 months	*location undisclosed*
• Van Dolah et al. (1998)	2 – > 12.5 years	South Carolina

Van Dolah et al. (1998) observed significant changes in the species composition of the recruited benthos, shifting from a dominance by amphipods to mollusks. During the time period monitored (> 12.5 years), the original species composition within the affected area was never restored due to the change in substrate composition (Van Dolah et al. 1998). Mining activities that changed bottom sediment composition were often associated with impacts of the greatest magnitude and most prolonged recovery, typically occurring in areas with little sand movement, with deep borrow pits or that were previously mined (COE 2001; Saloman et al. 1982). Comparison of borrow areas and control sites associated with a storm damage reduction project at Carolina Beach found few statistically significant differences in species abundance 0.5 and 1.5 years after sediment removal (Posey and Alphin 2001). However, after sediment removal, dominant species composition at the "borrow site" was more dissimilar to the control site than before sediment removal. The authors concluded that year to year variability in the benthic community, in addition to multiple hurricanes during the monitoring period, made effects from the project difficult to determine (Posey and Alphin 2001). Observed recovery at this site was more rapid than expected, due in

part to the configuration of the borrow areas. The borrow area was long (3 mi), relatively wide (0.5 mi), and most importantly, not excessively deep (5-10 ft deep) (M. Posey, UNC-W, pers. com., 2003). At "borrow sites" monitored off New Jersey, infaunal assemblages (diversity) recovered within one year after disturbance, while biomass and taxonomic richness took 1.5 to 2.5 years to fully recover (COE 2001). Because material was removed from a topographically diverse bottom, a deep pit was not created, leading the authors to conclude that time to recovery was reduced. In addition, strong water currents and dynamic sand movement in the project area facilitated more rapid infilling.

Repeated use of a "borrow site" for beach nourishment is generally not possible since the excavated areas tend to refill with more muddy substrate or have not completely refilled prior to the next renourishment interval (3 – 8 year cycles). Because of the slow recovery and change in sediment composition, Van Dolah (1998) stated that nearshore borrow areas must be viewed as a non-renewable resource and as the regions most impacted by beach nourishment projects (R. Van Dolah, SC DNR; pers. com., 2002). Locating "borrow sites" at specific soft bottom locations known to support seasonal aggregations of demersal fish, such as the critical overwintering area off the Outer Banks for juvenile Atlantic sturgeon, spiny dogfish, and striped bass, could negatively impact those species. "Borrow sites" established on ebb and flood tide deltas may recover relatively faster due to nearby longshore sediment transport. However, these deltas serve as important feeding sites to a number of commercially and recreationally important species, including red drum, striped bass, spot, Atlantic croaker, weakfish, blue crabs, and shrimp, and serve as spawning sites for red drum, weakfish, spotted sea trout, and blue crab. Removal of a major component of their diet could negatively impact these species (Peterson et al. 1999). Factors that appeared to maximize biological recovery rates include:

- Shallow excavation of borrow areas,
- Use of topographic highs, and
- Location in areas of high sand movement.

When "borrow areas" are necessary for beach nourishment projects, guidelines should strongly encourage siting protocol that maximizes biological recovery rates and does not degrade critical fish foraging areas .

Beach nourishment impacts at intertidal beach and adjacent subtidal bottom

Biological impacts of sediment disposal to the intertidal beach community have been studied by Hackney et al. (1996), Donoghue (1999), Jutte et al. (1999), Van Dolah et al. (1992), Reilly and Bellis (1983), Peterson et al. (2000b), and others. Studies of dredge disposal and storm damage reduction projects demonstrated an almost complete initial reduction in the number of benthic invertebrates in the intertidal zone, as well as in the subtidal zone and dry beach, immediately following the disturbance. The effect on smaller meio- and microfauna is unknown. The rate of reported biological recovery on nourished intertidal beaches has varied from about one month to one year, but in some cases longer (Table 6.4).

Table 6.4. Reported biological recovery times at nourished beaches.

Location	Biological recovery following beach nourishment	Reference
Atlantic Beach, N.C.	More than 3 months. Coquina clams in nearshore overwintering bottom killed initially by turbidity; delayed recruitment and repopulation; Haustoriid amphipods had not recovered after 3 months. Polychaete *S. squamata* recovered 15 – 30 days post nourishment.	Reilly and Bellis 1983
Atlantic Beach, N.C.	Densities of mole crabs and coquina clams were 86 – 99% lower than control sites, 5 – 10 weeks post-nourishment, during mid-summer.	Peterson et al. 2000
North Topsail, N.C.	After 1 year, mole crab, coquina clam, and amphipod abundance remained significantly less than at control sites and body size was significantly smaller. Polychaetes increased in abundance.	Lindquist and Manning 2001
Pea Island N.W.R., N.C.	2 – 9 months for coquina clams and mole crabs.	Donoghue 1999
Hilton Head, S.C.	Density and diversity returned to levels similar to control sites in 6 months.	Van Dolah et al. 1992
Folly Beach, S.C.	2 – 5 months, depending on benthic group and site, polychaetes recruiting earlier than mollusks.	Jutte et al. 1999
Panama City, F.L.	Large reductions in abundance and diversity remained after 2 years.	Rakocinski et al. 1993
Manasquan, N.J.	Abundance, biomass, and diversity completely recovered after 6.5 months. Recovery quickest when filling completed before low point in seasonal infaunal abundance and where grain size of fill material matched natural beach.	COE 2001

Factors likely affecting the recovery time of the intertidal beach community include:

- compatibility of deposited material with native sand (sediment grain size)
- volume of sand
- depth of filled sand
- length of area covered
- time of year
- time period between renourishment events on an individual site
- alteration of the beach geomorphology
- location placed on the beach

In the studies referenced above and others, biological impacts persisted longer when supplemented sand was either coarser (Peterson et al. 2000a; McLachlan 1996; Rakocinski et al. 1993; Rakocinski et al. 1996) or finer (Gorzelany and Nelson 1987; NRC 1995) than the existing sand. Increased grain size of the beach can result in significant reduction in species richness and abundance by 1) limiting body size, 2) limiting burrowing performance and other functions in some species, 3) changing the beach condition to a higher energy swash zone (McLachlan 1996). A decrease in grain size impacts the benthos by 1) smothering organisms, 2) clogging gills from sediment plumes, and 3) decreasing the interstitial space between sediment grains available to small burrowing invertebrates (Rakocinski et al. 1996). Current CRC rules state that sediment grain size shall be equal to or larger than that found naturally at the site. *More specific minimum and maximum grain size standards are needed to minimize biological impacts.*

The time period between renourishment events is also an important factor for successful recovery. Lindquist and Manning (2001) found that at a beach where dredge material was placed between April and June, and redeposited the following year (April – June) the abundance of the mole crabs, coquina clams

and amphipods was significantly lower than the control beach after one year. Also, mole crabs and coquina clams were significantly smaller in size than at control sites, indicating that repeated disturbance from beach disposal (once a year) prevented full recovery of the populations. Peterson et al. (2000b) also argued that recovery could be accelerated if projects were timed to occur before spring recruitment of benthos.

Dredge material from inlet dredging is often placed in nearshore water (< 30 ft deep) within the beach profile to enhance sand supply on the beach. Such sand placement in nearshore waters can delay the duration and reduce the magnitude of the benthos reduction on the beach, but cause additional impacts to subtidal bottom (Donoghue 1999). Monitoring of a nearshore disposal project that occurred on an ebb tide delta near Beaufort Inlet in March – April found that after eight months (December), infaunal invertebrates were only 50% as dense as that of the original benthic community, but mobile epifauna had fully recovered (Peterson et al. 1999). In the following two months (December – February), density estimates doubled , as new recruits rapidly entered the area (Peterson et al. 1999). Projects timed to occur in the winter, prior to peak infauna larval recruitment in the summer and fall, will speed up the recovery of intertidal benthic organisms within the impacted area (Donoghue 1999).

Alternatively, impacts to the intertidal and subtidal benthic community can be minimized by placing dredge material high on the beach, allowing more gradual sand redistribution and time for mobile invertebrates to move and adjust (Van Dolah et al. 1992). Typically most beach nourishment projects extend from the high beach into the intertidal and subtidal bottom. Even if sand is placed only on the dry beach, nearshore subtidal bottom can still be impacted if storm events transport the sand off the beach and across the seafloor. A study in North Carolina documented sand from a nourishment project transported offshore perpendicular to the beach and covering formerly muddy slough and channels (Thieler et al. 1998). Alteration of the sediment composition and temporary reduction in available benthos to demersal fish and crustaceans, could have a negative impact on species that favor muddy substrates, such as southern kingfish and shrimp. In summary, several conditions appear to minimize biological impacts of nourishment projects to the intertidal beach community. These include, but are not limited to:

- Use of sand similar in grain size and composition to original beach sands (specific minimum and maximum standard needed).
- Restrict beach nourishment to winter months to minimize mortality of infauna and enhance recovery rates of intertidal benthic organisms, an important prey source for many surf fish (Donoghue 1999).
- Limit time interval between projects to allow full recovery of benthic communities (1-2 years, depending on timing of project and compatablility of sediment).
- Limit linear length of nourishment projects to provide undisturbed area as a source of invertebrate colonists for the altered beach, and a food source for fish.

The extent of biological impacts from beach nourishment activities is determined not only by these individual conditions, such as grain size, time of project, frequency of reapplication, but by combinations of factors. *Because of the potential impact of beach nourishment and dredge disposal on soft bottom communities, there is a need for a coastwide Beach Management Plan that carefully reviews cumulative impacts of activities and provides ecologically based guidelines, including sediment compatibility standards, to minimize cumulative impacts. The CRC's beach nourishment rules should be evaluated and modified in a comprehensive manner as needed to minimize overall impacts from this activity. Additional research is also needed to more clearly quantify the cumulative impact of nearshore dredge disposal on fish populations.*

The largest biological impact of beach bulldozing appears to be reduction in ghost crab populations on the dry beach (Peterson et al. 2000). Lindquist and Manning (2001) found no significant impact on dominant beach invertebrates associated with beach bulldozing. No decline in surf fish or shorebird use at or adjacent to scraped beaches was observed. Peterson et al. (2000b) found that beach bulldozing at Bogue

Banks reduced the width of the intertidal beach, shifted sediment composition, and immediately reduced abundance of benthic organisms. Because of the relatively quick recovery on intertidal and shallow subtidal benthic communities and the relatively small area that occurs in subtidal waters, fish impacts from bulldozing should be less than other beach management activities. However, beach scraping has not been shown to provide any erosion control benefit, and has actually increased wind erosion of sand where created dunes were left unvegetated (Peterson et al. 2000b; McNish and Wells 1992; Tye 1983; Kerhin and Halka 1981). The CRC modified specific conditions for beach bulldozing in 2000 which should help minimize biological impacts if properly enforced, including time windows for work to be completed, maximum depth of scraping, and replanting of dunes.

Beach nourishment impacts on fish

Fish may be impacted by beach nourishment due to reduction in food availability, alteration of preferred topographic features, disturbance prior to or during spawning, or reduced visibility. Fish and invertebrate species that spend considerable time in the surf zone and feed on benthic invertebrates, such as Florida pompano, gulf kingfish, Atlantic croaker, spot, and shrimp, would be most vulnerable to beach nourishment activities. Very little monitoring has been done to assess the impacts of nourishment projects on fish distribution, feeding, growth, or survival.

A New Jersey study examined surf zone fish distribution, abundance and diet in response to ongoing nourishment projects (COE 2001). In the immediate vicinity, abundance of bluefish, a visual feeder, decreased and northern kingfish, a benthic feeder, appeared to increase. However, no long-term trends were detected in distribution or abundance. Stomach content analyses of kingfish and silversides did not suggest differences in prey availability between control and project sites.

In North Carolina the impact of a Brunswick County beach nourishment project on surf fish, benthic invertebrates, and water quality was evaluated from March 2001 to May 2002. Sand from the lower Cape Fear River dredging project was placed on Bald Head Island, Caswell Beach, Oak Island, and Holden Beach. Seining and trawling before and after the project found no significant differences in fish abundance or diversity between disturbed, undisturbed, and reference sites during any season. This was attributed to the high mobility and schooling behavior of the dominant fish species (anchovies and drum family), resulting in clustered and variable distribution. Although statistically not significant, gulf kingfish were less abundant at the disturbed sites than the undisturbed sites. The decline was thought to be at least partially due to the reduced availability of benthic invertebrates preferred by gulf kingfish (COE 2003). The intertidal benthic community was the most directly impacted by the beach nourishment project. Analysis of the effects of this project was limited by problems with the statistical design (COE 2003). Sample size was often insufficient to calculate confidence limits, partly due to uneven sampling between treatments (disturbed, undisturbed, reference). *Adequate monitoring of the effects of beach nourishment on the soft bottom community and associated surf fish populations is increasingly important as the number of beach nourishment projects increase and should be required for all large-scale or long-term nourishment projects.*

Status of beach nourishment from navigational dredge disposal projects

The COE is charged to maintain North Carolina's navigable inlets and ocean channels through dredging as necessary. Navigational dredging in inlets by the COE is allowed at any time of the year and is not subject to any mandatory dredging moratoriums unless sea turtle take quotas are exceeded. Industry-owned hopper dredges working in the Wilmington and Morehead port areas and Oregon Inlet have a voluntary dredge window of January 1 – May 31, to minimize taking of turtles (T. Wilder, COE, pers. com., 2003; NMFS 1997).

Seven inlets are maintenance dredged on a regular basis with a hopper or pipeline dredge. Many of the others are dredged periodically as needed with a side-cast dredge. Side-cast dredging can be conducted at

any time of the year (COE 1979). Material from a pipeline dredge is pumped onto a nearby downdrift beach. This method can move larger volumes of sediment, but often cannot be used in the inlets due to rough seas or shallow water depth. Material from a hopper dredge is disposed in the surf zone along the 10 foot depth contour, or transported to an offshore dredge disposal site. This is the most frequently used method in North Carolina's inlets. The hopper dredge can hold about 300 cubic yards of sand per load. Material from the sidecast dredge is moved from the center of the channel to the edge of the channel (T. Wilder, COE, pers. com., 2003).

Material from dredge disposal projects is put on or adjacent to ocean beaches in close proximity to the dredged site. Beaches receiving sand from dredged inlets and adjacent waterways are indicated in Table 6.5 and Map 6.3 a-c. Sand from these projects usually only covers a relatively short linear length of the beach (< one mile), generally close to the inlet where the sand originated. The amount of sand deposited and the frequency of dredging varies between sites and with each dredging event (Table 6.5). There are 51 miles of beach designated and approved for dredge disposal, but only about 16 miles of beach receive dredge material (T. Wilder, COE, pers. com., 2003). Areas receiving dredge disposal include several locations on Hatteras Island, south end of Ocracoke Island, Core Banks, both ends of Bogue Banks, Onslow Beach, several locations on Topsail Island, Wrightsville Beach, Masonboro Island, north end of Carolina Beach, Caswell Beach, Oak Island, east end of Ocean Isle Beach, and both ends of Bald Head Island. In addition, privately owned Figure 8 Island has received nourishment projects periodically, most recently in 2002 from the Mason Inlet relocation project.

Draft

Table 6.5. Ongoing COE dredge disposal projects on North Carolina beachs (Source: T. Wilder, COE, pers. com., 2003).

Dredging Project	Disposal location	Approved disposal limits (mi)	Actual disposal limits (mi)	Estimated quantity (cu. Yd.)
Avon Harbor vicinity, Avon	Hatteras Island, south of Avon Harbor and extend north.	3.1	0.4	< 50,000 every 5-6 yr.
Rodanthe Harbor vicinity, Rodanthe	Extends from south end of Pea Island NWR to south of Rodanthe Harbor.	0.9	0.4	<100,000 every 5-6 yr
Rollinson/ Hatteras	Hatteras Island south of Hatteras Harbor and extends 5.85 mi north of Frisco.	5.9	0.4	<60,000 every 2-3 yr
Silver Lake	Southwest end of Ocracoke Island.	0.4	0.4	<50,000 every 2-3 yr
Oregon Inlet	Pea Island south from Oregon inlet.	3.0	1.5	300,000 / year
Drum Inlet	Core Banks, extending 1 mi either side	2.0	1	298,000 initial, 100,000 maint.
Morehead City	Bogue Banks, from Beaufort Inlet west to Coral Bay Club, Pine Knoll Shores	7.3	5.2	3,500,000 every 8-10 yr.
AIWW	Pine Knoll Shores	2.0	0.4	<50,000 every 5-6 yr.
AIWW Bogue Inlet	Bogue Banks from Bogue Inlet east to Emerald Point Villas	1.0	0.4	<100,000 / year
AIWW	Camp Lejeune, from Browns Inlet west	1.6	1	<200,000 every 2-3 yr
AIWW, New River Inlet	N. Topsail Beach from inlet west to Maritime Way	1.5	0.8	<200,000 / yr
AIWW	Surf City opposite N.C. 50 bridge	1.0	0.04	<75,000 every 5-6 yr (only used in 1996)
AIWW	Topsail Island, Queen's Grant	0.6	0.6	<50,000 every 5-6 yr
AIWW, Topsail Inlet and Creek	Topsail Beach, north of Topsail Inlet	1.0	0.4	<75,000 / yr
AIWW, Mason Inlet crossing	North end Wrightsville Beach 2000' from Mason Inlet	0.4	0.4	<100,000 (not scheduled)
Masonboro sand bypassing	North end Masonboro Island, south from Masonboro Inlet	1.2	1	500,000 every 4 yr
AIWW, Carolina Beach Inlet, Snows Cut	South end Masonboro Island, from Carolina Beach Inlet north	1.3	0.4	<50,000 / yr
AIWW	North end of unincorp. Carolina Beach, south of Carolina Beach Inlet to town limit	0.8	0.4	<100,000 / yr
Cape Fear River, Wilmington Harbor	Bald Head Island	3.0		Approx. 1,000,000 / 2 yr.- total for Bald Head, Caswell, and northern Oak Island
Cape Fear River, Wilmington Harbor	Caswell Beach and northern part of Oak Island	4.7 mi initially, 2.8 mi./2 yr		
Cape Fear River, Wilmington Harbor	Sea Turtle Restoration Site, Oak Island (Continuing Authorities Project)	2.4		Only received one time from initial dredging
Cape Fear River, Wilmington Harbor	Oak Island, south of sea turtle project	4.9		Only received one time from initial dredging
Cape Fear River, Wilmington Harbor	Holden Beach	2.0		Only received one time from initial dredging
AIWW Cape Fear River to SC line	East end Ocean Isle Beach	0.6	0.6	<100,000 every 1-2 yr; 250,000 if Lockwood dredged (every 8-10yr)
Total		**50.7**	**16.14**	

Status of beach nourishment from storm damage reduction projects

Storm damage reduction projects involve dredging sand specifically to increase the width and height of the beach and dunes to reduce storm damage to infrastructure and private property adjacent to the beach. To implement a federally authorized and subsidized storm damage reduction project, local governments must follow a lengthy process that can take up to 10 years to initiate. A local government must first identify an erosion problem and request a study by the COE to determine if and how a project could be conducted. Numerous regulations and policies guide permit review and

authorization, although protection of fish habitat is not the primary consideration. DMF and other agencies are given an opportunity to comment to DCM and the COE on the potential impacts of a project to fisheries, fish habitat, and other environmental concerns. The MFC adopted a beach nourishment policy in 2000 to guide the permitting process to more fully consider fish habitat impacts (Appendix K).

The frequency and magnitude of beach nourishment has increased over time. From the 1960s to 2000, only nine miles of beach (3% of the ocean shoreline) had ongoing storm damage reduction projects - Wrightsville Beach, Carolina Beach, and Kure Beach (Table 6.6; Map 6.3 a-c). These projects were initially authorized and begun in the 1960s, although the first nourishment project in Wrightsville Beach occurred in 1939 (COE 1992). With the exception of Currituck County where there have been no nourishment projects, Onslow County has had the least beach renourishment, with only one small project in the 1990s. Currently there are 16 mi of beach along North Carolina's coast (5%) that have authorized and funded storm damage reduction projects ongoing. An additional 35 mi of beaches (11%) have authorization to conduct projects, and 104 mi of additional beaches (33%) are at some stage of requesting long-term beach nourishment (storm damage reduction projects). Beach renourishment of federally authorized storm reduction projects generally occurs on three or four year intervals. Potentially 155 mi or 48% of North Carolina's beaches could be renourished regularly if resources existed, and these beaches could be potentially impacted by such activities. This does not include approximately 16 mi of beach renourished periodically by disposal from channel, inlet, and port dredging.

Table 6.6. North Carolina beach communities with federally authorized or requested storm damage reduction projects (does not include beach disposal from navigational dredging projects). *[Source: T. Jarrett, COE, pers. com., 2004]*

Beach	PROJECT LENGTH (MILES)		
	Existing	Authorized	Requested
S. Kitty Hawk & N. Kill Devil Hills		4.5	2.2
Nags Head		10.5	
Hatteras Island			53 (NC 12 project)
Ocracoke Island			17 (NC 12 project)
Bogue Banks, excluding Atlantic B.			17
Onslow Beach		1.0	
North Topsail Beach			4
Surf City			5.5
Topsail Beach		3	5.5
Figure 8 Island	2		
Wrightsville Beach	3 (every 4 yrs)		
Carolina and Kure Beach	6 (every 3 yrs)		
Caswell Beach, southern part of Oak Island		7.3	
Holden Beach		5.7	
Ocean Isle	5.3		
Sunset Beach		2.7 (needs re-evaluation)	
Total	**16.3**	**34.7**	**104.2**

Preliminary examination of commercial gill net landings data for demersal feeding surf fish in counties with differing levels of beach nourishment activity indicate some relationship may exist between beach nourishment events and low landings (DMF, unpub. data). However, more information and analysis are needed to determine if beach nourishment events negatively impact surf fish abundance, CPUE, or landings. Given the increasing numbers of existing and requested nourishment projects over time, the cumulative impacts of activities on the intertidal and subtidal communities are also expected to increase. *To adequately and correctly assess the direct and cumulative impacts of beach nourishment activities on fish, their habitat, and biological recovery rates, thorough monitoring must be conducte*d. Increasing use of beach nourishment may have a cumulative impact on fish productivity of nearshore waters through impacts on the benthic community and alteration of natural barrier island processes. *Because beach nourishment has greatly increased in recent years, there is a need to complete a comprehensive beach management plan to provide guidelines to minimize long-term impacts. In addition, efforts should be made to educate local government officials and the general public (since these groups initiate and drive the demand for beach nourishment) on natural hazards associated with dynamic coastal systems*

Fishing gear impacts

The extent of habitat damage from fishing gear varies greatly with the gear type, habitat complexity, and amount of gear contact. While MFC rules are designed to minimize commercial fishing gear impacts to fisheries habitat, these restrictions primarily focus on restricting the use of highly destructive bottom disturbing gear from most structural habitats such as oyster or SAV beds. Soft bottom habitat, because of its low structure and dynamic nature, has historically been considered the most appropriate location to use bottom disturbing gear. There are some fishery rules that restrict bottom disturbing gears in soft bottom habitat, since DMF research found that their use disturbed soft bottom substrate. These include prohibition of trawls, dredges, and long haul seines in PNAs (15A NCAC 3N .0104) and prohibition of trawls, or mechanical shellfish gear in crab spawning sanctuaries (15A NCAC 3L .0205) in the five northern-most inlets of North Carolina during the blue crab spawning season (March-August).

Fishing related impacts to fish habitat have been reviewed and compiled in federal fishery management plans for managed species and have been summarized by in fishery management plans by SAFMC and MAFMC, as well as by DMF (1999), MFC (1996), Auster and Langton (1999), and Collie et al. (2000). The MFC Habitat and Water Quality Committee (MFC 1996) compiled a list of the gears used in North Carolina waters and their probable impacts (Appendix L). The gears with the greatest potential for damage to soft bottom or other habitats include dredges and trawls. The impacts of these gears and where they are used are discussed below.

Dredging

Of gears used in North Carolina, dredges are considered to be the most habitat destructive (DeAlteris et al. 1999; Collie et al. 2000). Oyster and crab dredging are conducted in limited areas in northern Pamlico Sound and its tributaries. Oyster dredging is conducted over shell bottom and was discussed in detail in the shell bottom section. Crab dredging is allowed in one area in northern Pamlico Sound (approximately 100,653 acres), primarily on soft bottom (Map 6.5), and is opened by proclamation from Jan 1 to March 1. Crab dredges are similar to oyster dredges, although the dredge teeth are sometimes longer on the crab dredge. Because of the gears' teeth, crab and oyster dredges can dig deep into the sediment and cause extensive sediment disturbance. Crab dredges are limited to a weight of 100 lb and can only be used in January and February (15A NCAC 3L .0203). Mechanical methods, as well as trawls and pots, for the taking of crabs is prohibited in designated Crab Spawning Sanctuaries from March through August. In recent years, fishing effort has been very low, with fewer than 10 crab dredge trips reported per year. Although the amount of fishing effort is low, this gear is documented to cause significant damage (DeAlteris et al. 1999; Collie et al. 2000). *Because less habitat damaging methods are available for harvesting crabs, MFC should prohibit crab dredging.*

There are two types of scallop dredges used in North Carolina. Bay scallop dredges are used in SAV beds. Refer to the SAV section for more information on this gear. Sea scallop dredges are used occasionally in the coastal ocean off Cape Lookout. Studies have found that scallop dredges cause extensive damage to hard bottom and significantly reduce habitat complexity on soft bottom and shell hash bottom (Auster et al. 1996; Currie and Parry 1996). Habitat complexity is reduced through flattening of mounds, filling of depressions, dispersing shell hash, and removing small biotic cover such as hydrozoans and sponges (Auster et al. 1996). Sea scallop dredging primarily occurs in deep coastal waters north of North Carolina. Dredging for sea scallops off North Carolina has been a sporadic fishery, primarily located in federal waters. Since 1994 commercial landings of sea scallop meats have been very low ranging from 13,815 lb in 1999 to 206,790 lb in 1995 (DMF 2001). Because of the location of the fishery and the low level of effort, no additional restrictions appear to be needed.

Hydraulic clam dredging and clam kicking were described in detail in the SAV chapter. Mechanical clamming, including kicking and dredging, accounts for approximately 21% of the annual hard clam landings (DMF, unpub. data). The dredging and kicking activity creates trenches and mounds of discarded material in soft bottom habitat, redistributing and resuspending sediment (Adkins et al. 1983). Water jets from the hydraulic dredge can penetrate 18 inches into bottom sediments, and uproot any biotic structure present (Godcharles 1971). Dredge tracks can remain present from a few days to more than one year and recolonization by vegetation can take months to begin. Recruitment of clams and other benthic invertebrates does not appear to be affected by hydraulic dredging (Godcharles 1971). Because of the severe impacts to habitats, both hydraulic clam dredging and clam kicking are restricted to open sand and mud bottoms, including areas frequently dredged as navigational channels. The locations where mechanical clam harvest is allowed is shown in Map 6.5. There are approximately 39,517 acres that are potentially available to mechanical clam harvest in portions of Core, Bogue, and Pamlico sounds, Newport, North, White Oak, and New rivers, and a portion of the ICW in Topsail Sound. The majority of mechanical harvest areas are located in Core Sound (29,951 acres). These fisheries may be opened by proclamation between Dec 1 and March 31. At this time, no changes are necessary to protect soft habitat because of the low frequency of the activity and dynamic nature of the habitat. However some changes are needed to better protect SAV and are discusses in that section.

Bottom trawling in estuarine waters

Bottom trawling is used more extensively than dredges on soft bottom habitat in both estuarine and coastal ocean waters. Bottom trawling in estuarine waters is used primarily to catch shrimp, although some crab trawling is also conducted. Flounder trawling is restricted to ocean waters. Bottom trawls are conical nets that are towed behind a fishing vessel, held open by water pressure against a pair of "otter boards" or "doors" that are attached to the front of the net. Three components of a bottom trawl can dig into the sediment: the doors, the weighted line at the opening of the net, and the tickler chains (which are sometimes added in front of the net to improve the harvest).

Impacts of shrimp and crab trawling in estuarine waters were reviewed and compiled by DMF (1999), at the request of the MFC and were reported to the General Assembly's Joint Legislative Commission on Seafood and Aquaculture. This report found that trawling can impact fish habitat by altering the physical structure or biological components of soft bottom. Pulling trawl nets across soft bottom reduces habitat complexity by (Auster and Langton 1999):

- directly removing or damaging epifauna
- removing benthic invertebrates which produce structure like burrows and pits
- smoothing sediment features of the seafloor, such as sediment ridges and contours

Gear contact can uproot and remove plants and invertebrates attached to the seafloor, such as algae, sponges, and worm tubes, and SAV, and can expose them to predators. This structure, although small relative to other benthic habitats, is important to certain species, such as *Sabellaria* worms, for

recruitment (Wilson 1968). Gear effects on bottom were described in the SAV chapter (ASFMC 2000). Trawl doors penetrate more than the rest of the gear and will penetrate deeper in muddy substrates. The change and reduction in the structural complexity of the seafloor and increase in turbidity from trawling can reduce feeding success of filter feeding invertebrates due to gill clogging, or increase predation due to increased exposure and reduced cover. Clam trawling (clam kicking) causes severe disturbance to bottom sediments. However, a study in North Carolina found no significant effect of this fishing activity on recruitment of hard clams or abundance of other benthic invertebrates in unvegetated sandy bottom (Peterson et al. 1987).

Reduced diversity and abundance of some benthic taxa are commonly observed in areas experiencing intense fishing activities (Auster and Langton 1999). A shift in dominant species and a reduction in community stability may also occur. Long-lived species, which take more time to recover from fishing disturbance, may be temporarily or indefinitely replaced by short-lived species. Sediment resuspension by trawling can significantly increase the suspended sediment load (turbidity) over soft bottom on the outer shelf. Increased turbidity reduces light penetration and consequently reduces primary productivity of benthic microflora on the seafloor as well as phytoplankton in the water column (Auster and Langton 1999). Decreased primary productivity will affect demersal zooplankton that, in turn, supports higher trophic layers. A reduction in filter feeders on the subtidal bottom can result in reduced water clearing capacity in the water column (Auster and Langton 1999). However whether these effects, given the frequency, magnitude, and location of trawling, are having a significant negative impact on soft bottom habitat in North Carolina's estuarine system, is not known. Trawling can affect primary productivity of both soft bottom and water column by (DMF 1999):

- stimulating chemical exchange between resuspended sediment and the water column
- increasing turbidity and reducing light availability at the surface of soft bottom
- reducing primary production of benthic microalgae

Increased chemical exchange between bottom sediments and the water column (benthic-pelagic coupling) can have positive and negative effects on estuarine systems. Nutrients released into the water column can greatly increase nitrogen and phosphorus levels, stimulating phytoplankton growth, as well as enhancing secondary productivity of herbivorous zooplankton and larger prey (DMF 1999). Eventually, the remains of plankton and other organisms will settle, adding to the food available to benthic deposit feeders. However, if large amounts of organic matter are resuspended, the subsequent increase in plankton can reduce water oxygen levels, causing hypoxia and anoxia (West et al. 1994; Paerl et al. 1998). By resuspending sediments, trawling can make inorganic and organic pollutants (i.e., heavy metals and pesticides, respectively) available in the water column (Kinnish 1992; DMF 1999). Such toxins can negatively affect productivity and may also accumulate in organisms through food chain interactions.

While some consider trawling to be physically disruptive to the bottom and potentially harmful to the benthic community due to gear damage, sedimentation, predation exposure, and reduction in benthic primary production (Auster and Langton 1998), others feel that trawling may mimic natural disturbances and stimulate benthic production, enhancing fish production. In a literature review of the effects of trawling in estuarine waters, DMF (1999) noted that multiple studies demonstrated the presence and absence of long-term effects of trawling in estuarine waters. No or minimal long-term impacts were reported in Van Dolah (1991), MacKenzie (1982), and Currie and Parry (1996). Of these studies, Van Dolah (1991) was located closest to North Carolina, in a South Carolina estuary. After five months of trawling, Van Dolah (1991) found no significant change in abundance, diversity, or composition of soft bottom habitat. Studies which have found long-term habitat impacts include Collie et al. (1997), Engel and Kvitek (1998), Brown (1989), and Bradstock and Gordon (1983).

The DMF trawl report recommended that additional studies be done in North Carolina estuarine waters to better assess the impact of trawling on the estuarine environment. *Further analysis is needed to identify the location, duration and initiation of trawling over soft bottom habitat as well as over structured*

habitats, such as shell bottom and SAV. It is also important to quantify the effects of trawling on the habitat. Specific research needed to evaluate the habitat impacts of trawling include (DMF 1999):

- *Determine the intensity, duration, and spatial scale of trawling effort in different regions of North Carolina.*
- *Determine turbidity levels generated by different gear configurations and the subsequent rates of redeposition.*
- *Determine the physical effect of natural forms of disturbance to compare significance of trawling effects.*
- *Sample areas normally subjected to trawling to describe the local benthic community, identifying seasonal cycles of species abundance and recruitment, to determine the times of year that benthos would be most sensitive to trawling disturbance.*
- *Measure in situ rates of growth, mortality, and recruitment of selected benthic organisms that are exposed to trawling.*
- *Evaluate the effect of trawling on benthic algal growth and primary productivity overall.*
- *Determine the impact of trawling on secondary productivity.*

Attempting to answer questions in the DMF trawl report, Cahoon et al. (2002) studied changes in benthic microalgae, demersal zooplankton, benthic macroalgae (important food sources for recreationally and commercially important species) in the Pamlico River estuary in 1999-2000. Demersal zooplankton include small crustaceans, nematodes, and other animals that are important grazers of benthic microalgae and prey for larger fish and invertebrates. Experimental trawling was conducted to document natural seasonal changes in the benthic community, examine changes before and after experimental trawling, and compare regularly trawled and untrawled areas. No significant differences were recorded in benthic algal biomass prior to and after experimental trawling. In comparing commercially trawled and untrawled areas, benthic microalgae were more abundant in the untrawled sites. This could be because benthic algae in trawled areas are resuspended into the water column. Nematodes, an important food source for shrimp, were the most abundant demersal organism found. The authors concluded that because the soft bottom community in shallow systems is frequently subjected to disturbance (such as exposure to waves and currents), trawling was not detrimental (Cahoon et al. 2002). However, since the experimental treatment consisted of one trawling pass, observed changes do not accurately reflect those consistent with chronic trawling. A key issue in determining if trawling is having a negative impact to soft bottom communities is the frequency and intensity of disturbance. *Further analysis is needed to spatially quantify where, how often, and when trawling occurs in specific areas of soft bottom habitat.*

The impact of trawling and associated bottom changes on fish populations also depends in part on each species' habitat dependence (Auster and Langton 1998). Where a life stage of a demersal species is highly dependent (obligate) on the structural components of a habitat where trawling occurs, particularly for recruitment, there is a greater potential for that species to be impacted by trawling (Auster and Langton 1998). However, if individuals can move to and survive in alternative habitats, impacts may be less severe (i.e., adult flounder foraging over ocean bottom can occupy other habitats) (DMF 1999). Primary nursery areas and inlets are described as "recruitment bottlenecks" for estuarine dependent species in DMF (1999). Since larval flounder, shrimp, and Atlantic croaker must pass through inlets and recruit to shallow PNAs, trawling impacts in inlets and PNAs could be greater than trawling in ocean waters. *Protection of these "recruitment bottlenecks" from trawling or other impacts is therefore very important for estuarine dependent fish and invertebrates.* The current MFC restrictions on trawling protect PNAs. However, there are productive shallow water areas of soft bottom that are not designated as primary or secondary nursery areas but still serve as important habitat to many juvenile fish and invertebrates. *Shallow areas where trawling is currently allowed should be re-examined to determine if additional restrictions are necessary.* There are also other non-habitat related concerns regarding trawling in estuarine waters, including bycatch or socio-economic reasons which may warrant additional restrictions on trawling in estuarine waters. *However, further studies are needed to more accurately assess if trawling is having a negative effect on soft bottom habitat and justify if additional closures are*

necessary for habitat concerns.

Bottom trawling in ocean waters

Many studies have been conducted around the world assessing the effect of trawling on soft bottom habitat in offshore waters. A thorough review of literature on fishing impacts to continental shelf benthos quantified impacts via a meta-analysis, examining data derived in part from studies of otter trawl effects on subtidal bottom in eastern North America (Table 6.7) (Collie et al. 2000). Some of their conclusions included:

- Otter and beam trawling were found to have fewer negative impacts on benthos than intertidal or scallop dredging or intertidal raking.
- In subtidal bottom, sand habitats were the least impacted, and muddy sand and gravel the most impacted.
- In muddy sand, polychaetes and large bivalves were most negatively impacted. Smaller bodied organisms are displaced by pressure waves in front of fishing gear.
- Depth and scale of fishing had insignificant effect on initial impact but significant effect on recovery. Recovery is slower where the spatial scale of impact is larger and in deeper waters where the bottom is more stable.
- Recovery was most rapid in less physically stable habitats such as sandy bottom (recovery in sand, estimated from modeling, was approximately 100 days).
- Benthos most impacted were Anthozoa (corals and anemones) and Malacostraca (crabs, amphipods), while copepods and ostracods were least impacted.
- Benthos had more negative responses to chronic disturbances than to acute disturbances.
- Epifaunal organisms are less abundant in areas subjected to intensive bottom fishing.
- Results suggested that fish and benthos in areas heavily fished would shift from communities dominated by high biomass species towards those with high abundance of small-sized organisms.
- *Large- scale long-term experiments with and without fishing pressure are needed, rather than short-term small-scale studies, to examine and better quantify cumulative fishing impacts and recovery patterns.*

Table 6.7. Trawl impact studies on the continental shelf of eastern North America.

Reference	Habitat	Depth (m)	Recovery Period (days)
Van Dolah et al. (1991)	Hard bottom	20	365
Kaiser et al. (1996)	Gravel	94	n/a
Van Dolah et al. (1991)	Sand	20	180
Van Dolah et al. (1991)	Sand	8	180
Auster et al. (1996)	Sand	30	3,650

These conclusions suggest that the dynamic soft bottom community found in nearshore ocean communities is less impacted by trawling and recovers much quicker than in estuarine systems. However, some long-term impacts to the benthic community may occur, especially to the epibiota depending on the frequency of trawling, and site-specific characteristics.

Status and trends of estuarine and ocean trawling

Trawling is primarily allowed in relatively deeper soft bottom areas. Maps 4.8 - 4.10 (from shell bottom) show the areas where trawling is currently not allowed in estuarine waters. Use of trawl nets is not allowed in Albemarle Sound and is not allowed for taking of finfish in internal (estuarine) waters (15A NCAC 3L .0205, 15A NCAC 3J .0104(a&b)). Shrimp trawling is not allowed in primary or secondary nursery areas (15A NCAC 3N .0105), or in No Trawl Areas (15A NCAC 3R .0106). In North Carolina, bottom trawling in ocean waters is prohibited over hard bottom but is allowed over most soft bottom

communities. Trawling is prohibited in military prohibited areas (15A NCAC 3I .0110 and 3R .0102), a designated sea turtle sanctuary seaward of Onslow Beach from June 1 to August 31 (15A NCAC 3I .0107 and 3R .0101), within 0.5mi of the beach from Virginia to Oregon Inlet (15A NCAC 3J .0202), and in designated crab spawning sanctuaries from March 1 to August 1 (15A NCAC 3L .0205). Map 6.6 a-c shows areas where trawling and some other gears are restricted over soft bottom in ocean waters. The purpose of these regulations is to protect spawning areas and reduce bycatch or user conflicts.

Annual effort with various commercial trawling gears in North Carolina waterbodies is shown in Table 6.8 (DMF, unpub. data). Commercial shrimp trawling accounts for the majority of trawl trips (92% in 2002) (Table 6.8). About 75-80% of shrimp trawl trips occur in estuarine waters, with the remainder in ocean waters, primarily within state territorial seas (<3 mi offshore) off the central and southern coast of North Carolina. Total annual shrimp trawling effort has decreased since 1995 by about 5,500 trips. Total annual shrimp trawling effort has fluctuated with shrimp abundance but appears to have gradually declined since 1994. However, the lower commercial fishing effort observed from 1999 – 2002, compare to earlier years is thought to be mostly due to a change in licensing procedure (R. Carpenter, DMF, pers. com., 2004). In 1999 a recreational commercial gear license became available to fishermen. Under this license, shrimp may be caught recreationally using a trawl, but cannot be sold. Some fishermen with commercial licenses prior to this, switched from a standard commercial gear license (SCGL) to a recreational commercial gear license (RCGL). Effort from RCGL licenses are not included in the data shown in Table 6.8. In 2002 approximately 5000 trips for shrimp were reported (DMF, unpub. data).

Regionally, shrimp trawling effort has generally been greatest in Core and Bogue sounds and associated estuaries (3,400-7,200 trips/year) (Table 6.8). Pamlico Sound and associated rivers and estuaries account for the second largest number of trawl trips per year, ranging from 2,900-5,500 trips/year. In 2000 and 2002, however, the Pamlico region accounted for slightly more trips than the Core/Bogue waters. Decreased effort in Core/Bogue sounds is not attributed to changes in shrimp management or habitat condition. In ocean waters, shrimp trawling is highly concentrated in the southern portion of the state (Onslow through Brunswick counties), primarily in the summer (approximately 2,300-3,400 trips/year) (Figure 6.6). In contrast, the annual effort in the central district (Carteret County) has ranged from 137 to 457 trips per year, and in the northern district (Virginia line through Hyde County) has ranged from 2 to 69 trips per year. Commercial shrimp trawl effort has remained relatively stable over time in the southern portion of the state.

Over 99% of crab trawling occurs in estuarine waters, while all directed flounder trawling (specially targeting flounder) occurs in ocean waters (i.e., no directed trawling for finfish is allowed in internal waters). The majority of crab trawling occurs in Pamlico Sound and adjacent estuarine rivers, followed by Core/Bogue sounds and estuaries. Flounder trawling effort occurs primarily in the northern and central portions of North Carolina's coastal waters. Effort in the northern district has varied from 14 trips in 1994 to 123 trips in 2002. In the central district, trips seem to be declining over time with a peak of 95 trips in 1996 and 19 trips in 2002 (Table 6.8). Overall, current bottom trawling effort in estuarine waters for all fishery species is greatest in Pamlico Sound and associated estuaries.

Table 6.8. Annual number of trips reported for shrimp, crab, and flounder trawls in estuarine and ocean waters [1], 1994-2002 (DMF, unpub. data).

[1] Albemarle Area: Albemarle Sound, Currituck sound, and all tributaries of Albemarle Sound.
Pamlico Area: Pamlico, Croatan, and Roanoke sounds; Pamlico, Bay, Neuse, and Pungo rivers.
Core/Bogue Area: Core and Bogue sounds; Newport, White Oak, and North rivers.
Southern Area: Masonboro, Stump, and Topsail sounds; Cape Fear, New, Shallotte, and Lockwood Folly rivers; ICW.
Northern district ocean waters: Virginia line through Hyde County.
Central district ocean waters: Carteret County.
Southern district ocean waters: Onslow County to the South Carolina line.

Water quality degradation

The condition of soft bottom is determined by the character and quality of bottom sediments and the quality of the overlying water column. Solids and organic matter in the water column eventually settle out and become a part of the soft bottom habitat. However, soft bottom sediments can also be resuspended by disturbances (e.g., storms and human activities such as dredging). The cycling of

material between the bottom and the water column was discussed previously in this chapter and in the water column chapter. In general, bottom sediments tend to act more as a sink than a source with regards to benthic-pelagic coupling. Aquatic organisms can accumulate pollutants from the sediment or the water column. Because water quality inevitably affects soft bottom (i.e., anoxia in the water column leads to increased production of hydrogen sulfide (H_2S) a gas that is toxic to aquatic life, in bottom sediments), many of the same threats to the water column are threats to soft bottom. The primary pollutants of concern to soft bottom are discussed below.

Toxic chemicals

Toxic chemicals that tend to accumulate in bottom sediments include:

- heavy metals
- polycyclic aromatic hydrocarbons (PAHs)
- petroleum hydrocarbons
- pesticides
- polychlorinated biphenyls (PCBs)
- ammonia

Of the heavy metals, arsenic, copper, cadmium, chromium, nickel, lead, zinc, tin, and mercury are among the greatest concerns. While toxins can fluctuate between the sediment and water column, concentrations of toxic chemicals tend to accumulate in sediments to several orders of greater magnitude than overlying waters (Kwon and Lee 2001). The bioavailability and transport of a chemical depends on the form of the chemical incorporated into the sediments, the feeding habits and condition of aquatic organisms, and the physical and chemical conditions of the environment. Because toxins can accumulate and persist over time, even chemicals that have been banned since 1977, such as DDT, Diedrin and TBT, continue to be found in sediments (Marburger et al. 2002). Toxic chemicals can become active in soft bottom sediment or overlying waters through several mechanisms, including resuspension from natural weather events or human activities. Toxins can also be active in surface waters , when dry sediment is hydrated from rainfall or runoff, toxic chemicals in the soils become oxidized, and heavy metals are released and transported downstream by heavy rains or water movements. Also, several studies have shown that mercury and other metals are released from peat soils subjected to intensive drainage (Evans et al. 1984; Gregary et al. 1984).

Because low concentrations of heavy metals in the water column can be easily incorporated into fine-grained sediment, chemicals can accumulate in the sediment to toxic levels and be resuspended into the water column (Riggs et al. 1991). Studies have shown that fine-grained sediments are the primary reservoir for heavy metals, particularly organic rich muds (ORM) (Riggs et al. 1991). Since organic rich muds are the most extensive sediment type in North Carolina's estuaries and since many primary nursery areas are composed of ORM, resuspension of contaminated ORM sediments in PNAs is of particular concern.

Contaminated sediments affect benthic feeding fish and invertebrates in several ways. Some toxins can inhibit or alter reproduction and development of marine and aquatic organisms, or cause mortality in some situations (Gould et al. 1994; Weis and Weis 1989). Large spills of toxic chemicals, such as pesticides or petroleum products, can result in fish kill events. In North Carolina, spills of pesticide, chlorinated water, and sewage waste were responsible for 8% of fish kill events in 2001 (DWQ 2001). Some heavy metals and pesticides cause hormone alterations that affect reproduction (Wilbur and Pentony 1999). Certain PAHs have been shown to cause mutations or cancer in fish (White and Triplett 2002). Documented effects of PAHs to flatfish include DNA damage, liver lesions, and impacts on growth and reproduction (Johnson et al. 2002).

Early life stages (embryos and larvae) of fish are most susceptible to toxins (Gould et al. 1994; Funderburk et al. 1991; Rice et al. 2001). Visible indications of heavy contamination are development of lesions, deformities, and tumors on fish or high mortality rates of larvae. Anadromous fish larvae are particularly sensitive to many toxins (Funderburk et al. 1991). In Alaskan waters, salmon eggs and larvae were killed and damaged for up to four years following long-term exposure to low concentrations of weathered crude oil, and migrating salmon fry had reduced growth rates and population reductions (Rice et al. 2001). Mollusks are known to be very sensitive to petroleum products, pesticides, and TBT, with relatively low levels of exposure affecting reproduction, tissue development, growth, and survival (Funderburk et al. 1991) (refer to shell bottom section for toxicity levels). Because macrobenthic invertebrate diversity significantly declines with increasing sediment contamination (Brown et al. 2000; Dauer and Weisberg 2000; Weis et al. 1998), food resources for benthic feeders may be limited in areas having significant contamination.

Lethal and sublethal levels of toxicity are known for some benthic aquatic species. However, most information comes from acute toxicity tests conducted in laboratory settings on standard test species. Data are lacking on chronic or sublethal toxicity levels for many important fishery species and interactions of contaminants in the field. Following oil spills, sub-lethal levels of contamination can delay population recovery due to indirect effects, and may lead to increased fish mortality where predation risk is size-dependent (Peterson et al. 2003). *More information is needed on the in situ effects of various contaminant levels, in combination with other contaminants and existing environmental stressors, to many important fish species in North Carolina.*

While the survival of some aquatic organisms is affected by toxins, other organisms survive and bioaccumulate the chemicals to toxic levels, passing them along in the food chain. Multiple studies have shown clear connections between concentrations of toxins in sediments and those in benthic feeding fish and invertebrates (Marburger et al. 2002; Kirby et al. 2001). Heavy metal contamination of sediments has been documented to result in elevated trace metal concentrations in benthic feeding striped mullet, shrimp, oysters, and flounder (Kirby et al. 2001; Livingstone 2001). Largemouth bass and catfish, stocked in a restored and flooded freshwater wetland, had high concentrations of organochlorine (chlordane, DDT, dieldrin) and internal contaminants were significantly correlated to contaminant levels in the sediment (Marburger et al. 2002). Toxic contaminants are also considered one of the most serious threats to native freshwater mussels, which are the most imperiled fauna in North America (Keller 1996).

The bioaccumulation of toxins in fish may pose a risk to human health. High levels of mercury have been found in four saltwater fish species (sharks, swordfish, tilefish, and king mackerel) and three freshwater species (bowfin, largemouth bass, and chain pickerel). Fish consumption advisories have been posted for all of these species (Div. Health Human Services website, 10/2003). The saltwater fish consumption advisory for sharks, swordfish, tilefish and king mackerel covers the entire state of North Carolina and much of the lower East Coast. The fish advisory for bowfin, largemouth bass and chain pickerel extends south and east from Interstate 85. In addition, several site-specific advisories exist. Those are listed on the DHHS website. Limits on consumption of catfish and carp due to dioxin contamination exist for Albemarle Sound, the lower portion of Roanoke River from Williamston to the mouth of Albemarle Sound, all of Welch Creek, a tributary of Roanoke River, and Walters Lake, a reservoir.

Toxic chemicals come from localized point sources as well as diffuse nonpoint sources. Point sources include industrial and municipal waste discharges. Nonpoint sources of toxins include urban runoff containing household and yard chemicals, roadways, marinas and docks, boating activity, runoff from agriculture and forestry, industrial emissions, spills from industrial shipping, and dredge spoil disposal (Wilbur and Pentony 1999). Refer to the water column section for more detailed information on the sources of toxic chemicals.

The extent of sediment contamination in North Carolina coastal waters is not well known. Sediment

sampling is not conducted by the DWQ since there are no sediment standards in the state. Studies examining sediment contamination at sites in North Carolina soft bottom have found various levels of contamination. The EPA Environmental Assessment Program surveyed 165 sites within North Carolina's sounds and rivers during 1994-1997 to evaluate condition of bottom sediments (Hackney et al. 1998). Highest contamination levels occurred in low salinity areas with low flushing and high river discharge. Benthic populations were dominated by tolerant opportunistic species and benthic communities had low species richness. Laboratory bioassays showed that sediments from many sites were toxic to biological organisms. However, because of the low sample size, frequency of sampling, and the confounding effects of hypoxia in areas sampled, results from this study may not accurately assess the condition of North Carolina sediments (C. Currin, NOAA, pers. com., 2003).

Concentrations of heavy metals in the Neuse and Pamlico estuaries have been assessed (Riggs et al. 1991; Riggs et al. 1989). In the Neuse River, surface sediments were found to contain elevated levels of several heavy metals, including zinc, copper, lead, and arsenic. Furthermore, 17 areas between New Bern and the mouth of the river were identified as "contaminated areas of concern". The contaminated sites were primarily attributed to permitted municipal and industrial treatment plant discharges. Marinas were also found to contribute substantial amounts of copper and variable amounts of zinc and lead. Non-point sources were more difficult to evaluate. In the Pamlico River, heavy metal contamination was less severe, although arsenic, cobalt, and titanium exceeded the levels found in the Neuse River. These studies suggest that sediment contamination in some estuarine areas, especially those where both organic rich mud and waste water discharges are present, may be significant and could affect fish populations and the base of their food chain. *To better determine if contaminated sediment is a significant threat to coastal fish habitat, the distribution and concentration of heavy metals and other toxic contaminants in freshwater and estuarine sediments needs to be adequately assessed and areas of greatest concern need to be identified. Continued minimization of point and nonpoint sources of toxic contaminants is vital for protecting not only soft bottom but also the other fisheries habitat.*

Nutrients

Increased nutrient loading and accumulation in bottom sediments is another concern to this habitat. The effects of nutrient enrichment are complicated by additional stressors, such as toxins or hydrological modifications, and by benthic-pelagic coupling (Riedel et al. 2003). High concentrations of organic material in bottom sediments serve as continual sources of additional nutrients to the water column, which can fuel algal blooms. In the shallow Neuse River estuary, high but variable rate of exchange of nutrients between the water column and soft bottom were noted, with soft bottom efficiently storing and providing nutrients that can fuel algal blooms that may lead to hypoxia (Luettich et al. 1999). When nutrient loading reductions occur, a decline in nutrient levels may not be observed in a water body until the nutrient supply in the sediment is depleted (Luettich et al. 1999), making management strategies difficult to evaluate in the short term. Work is currently underway to determine the contribution of resuspended nutrients from bottom sediments to phytoplankton production (<http://www.marine.unc.edu/Paerllab/research/mudboy>, 2003). *Long-term monitoring is required, in combination with management actions that reduce discharge concentrations, to determine effectiveness and future management needs.*

Soft bottoms in North Carolina's estuaries tend to store nutrients for several reasons (Peterson and Peterson 1979). Small clay sized sediment particles that are abundant in ORM adsorb nutrients readily. In addition, suspension feeding invertebrates remove nutrients and particles from the water column which later are transformed and deposited on the bottom as feces (a process known as biodeposition). These nutrients can become stored in the sediment, but later can be resuspended into the water column, maintaining nutrient concentrations at high levels in estuarine waters. The ebb and flood circulation increases the residence time of particles in estuarine waters, further retaining nutrients in the system (Peterson and Peterson 1979). Results from extensive monitoring in the Neuse River found that large quantities of nutrients were stored in the sediment. Refer to the water column section for detailed

discussion of the sources and status of nutrient enrichment in the water column.

Oxygen-depleted sediment

Adequate supply of dissolved oxygen is critical to survival of sessile benthic invertebrates and fish living on or in soft bottom habitat. In freshwater systems, low oxygen levels resulting from eutrophication has been suggested as an important source of mortality in mussels (Neves et al. 1997). In mesohaline estuaries low oxygen events occur when the water column becomes stratified for a long period, particularly during summer in areas of deeper water (Tenore 1972). If stratification persists, hypoxic events in the water column can cause changes in the physical and chemical conditions at the sediment-water interface, lead to stress or mortality of benthic organisms, and reduce species richness (Tenore 1972). In the benthic community, polychaetes tend to be most tolerant to low oxygen, followed by bivalves and then crustaceans (Diaz and Rosenberg 1995). Severe oxygen depletion in the sediment also results in release of toxic levels of sulfide into bottom waters (Luettich et al. 1999).

Mass mortality of benthic infauna due to anoxia and toxic sulfide levels has been documented in the deeper portions of the Neuse River estuary, in association with stratification of the water column in the summer (Luettich et al. 1999; Lenihan and Peterson 1998). During these events, oxygen depletion caused mass mortality of infauna such as clams and worms. Epifauna like oysters and mud crabs and some benthic fish, like blennies, also died when adequate tall refuge (oyster reefs) with oxygenated water was not available (Lenihan and Peterson 1998). More mobile benthos, such as blue crabs, left their burrows when oxygen was not available and moved to shallower or higher areas. In 1997 during a large hypoxic event in the Neuse River estuary, the abundance and biomass of *Macoma balthica* and *M. mitchelli*, the dominant benthic invertebrates and critical food sources for demersal fishes such as spot and croaker, declined by 90 - 100% over a 100 km^2 area (Buzelli et al. 2002). The areas of high benthic mortality coincided with the area estimated to have been the most severely oxygen depleted.

Low oxygen in bottom sediments can also affect the primary productivity of soft bottom and predation on the benthic community. Benthic microalgae are limited to oxygenated sediments (MacIntyre et al. 1996). During a severe anoxic event, mortality of benthic microalgae can occur, due to anaerobic sediments and the higher turbidity that often accompanies the stratification of the water column (M. Posey, UNC-W, pers. com., 2003). Predation on members of the benthic community by species such as flounder, spot, blue crabs, and croaker generally increases in the short-term since burrowing organisms tend to move into the shallowest sediment layers to avoid sulfide release and lack of oxygen in deeper sediments (Luettich et al. 1999). However, the overall reduction in prey could decrease long-term fish production (P. Peterson, UNC-CH, pers. com., 2004). Results from statistical modeling, utilizing field data from the Neuse River, indicated that benthic invertebrate mortality, resulting from intensified hypoxia events, reduced total biomass of heterotrophs (demersal predatory fish and crabs) during the summer by 51% in 1997 and 17% in 1998 (Baird et al. 2004). The decrease in available energy (fewer benthic invertebrates) greatly reduced the ecosystem's ability to transfer energy to higher trophic levels at the time of year most needed by juvenile fish (Baird et al. 2004).

When the benthic community is depleted by a low oxygen event, the pattern of recolonization of the soft bottom will affect higher trophic levels differently over time (Luettich et al. 1999). Opportunistic, fast-growing species of polychaetes and copepods will begin to recolonize the bottom first. Juvenile clams and larger polychaetes will recruit afterwards. The various successional stages may affect or benefit different benthic feeders to differing extents. For example, early successional communities composed of very small, shallow-burrowing opportunists (capitellid worms) and meiofauna may favor small species, such as penaeid shrimp and larval and juvenile croaker and red drum, but not provide food for large adult fish species. Partially recovered benthic communities consisting of polychaetes and small juvenile clams could benefit demersal species like spot, croaker and blue crabs. A fully recovered community with deep burrowing polychaetes and large clams might benefit adult spot and hogchoker but not benefit shrimp (Luettich et al. 1999).

While hypoxia and anoxia can occur naturally, they can also be attributed, in part, to anthropogenic changes in the system, including excess nutrient and organic loading from waste discharges, nonpoint runoff, streambank erosion, and sedimentation (Schueler 1997). In the Neuse River system, MODMON studies found that the sediment oxygen demand is much greater than the biological oxygen demand in the water column. Oxygen depletion in the water column was positively correlated with accumulation of organic material in the sediments (Luettich et al. 1999). Site-specific information on sediment condition is generally lacking in other areas of North Carolina. Several studies have indicated that the frequency, duration, and spatial extent of low oxygen events have increased over the years due to increasing eutrophication of coastal waters from human and animal waste discharges, greater fertilizer use, loss of wetlands, and increased atmospheric nitrogen deposition (Buzelli et al. 2002; Paerl 1985; Cooper and Brush 1991; Dyer and Orth 1994). *More information is needed to understand the consequences on the estuarine food web and to what extent anoxia is impacting the soft bottom community.* As hypoxia and anoxia of bottom sediments becomes more frequent, the quality of soft bottom habitat will deteriorate. *Efforts are needed to reduce anthropogenic nutrient loading, particularly in systems that have a history of hypoxia and anoxia.* Fish kill events that have been attributed to low oxygen can be used as an indication of these hot spot areas.

Turbidity and sedimentation

Organisms in soft bottom habitat are adapted to shifting and changing sediments. Shoreline erosion and stormwater runoff transport sediment into coastal waters, which helps maintain shallow water habitat. However, when sedimentation is excessive, there can be negative impacts. Impacts of sedimentation include (Schueler 1997):

- Physical smothering of benthic invertebrates
- Reduced survival of fish eggs
- Destruction of fish spawning areas in freshwater streams
- Elimination of sensitive species such as anadromous fish or darters
- Increase in sediment oxygen demand and depletion of oxygen
- Decline in freshwater mussels
- Reduced channel capacity, and subsequent acceleration of downstream bank erosion and flooding

The primary areas that are adversely affected by sedimentation are freshwater systems and upstream estuarine systems. The effects of sedimentation can be very gradual. Excessive deposition of sediments in a stream over time causes the depth and velocity to decrease and the width to increase. Consequently, the number and depth of riffle pools, and the temperature gradients within them, decrease. These riffle pools are important habitat for some fish species, such as minnows and darters (AFS 2003). The deposition of silt and fine sediment in gravel bottom rivers and streams fills the interstices of the gravel, and can decrease dissolved oxygen content if the organic content is high. Most North Carolina coastal rivers and streams do not consist of gravel substrate, however.

Excess sedimentation can reduce or eliminate aquatic insect larvae from stream bottoms (AFS 2003). These larvae are the basic fish food source in freshwater streams, and impacts to them can affect the productivity of associated fish species (AFS 2003). High levels of suspended sediment in an estuarine or marine habitat can greatly reduce successful settlement of larval clams and oysters, and can smother other benthic invertebrates (AFS 2003). In some areas, historic oyster bars have been completely covered with fine sediment and mud (P. Peterson, UNC-CH, pers. com., 2004). Refer to the water column section for information on habitat degradation from sedimentation and options for addressing sedimentation.

Excessive sedimentation has been cited as the major cause of freshwater mussel decline in the United States since the late 1800s (Box and Mossa 1999; Neves et al. 1997). Poor land use practices, including

construction and road building activities, agriculture, and forestry, dams, reservoirs, and channelization are among the causes cited for sedimentation (Box and Mossa 1999; Neves et al. 1997). Because freshwater mussels are dependent on specific host fish to complete their reproductive cycle, changes in resident fish populations due to dams channelization, or other habitat alterations, jeopardize survival of mussels (Neves et al. 1997). The decline in mussel populations in North Carolina is considered severe (Neves et al. 1997). Over 50% of approximately 60 native freshwater mussels are designated Endangered, Threatened, of Special Concern within the state and approximately 22 of these occur within coastal draining riverbasins (Neves et al. 1997; <http://www.ncwildlife.org>, April 2004). The Tar River spinymussel (*Elliptio steinstansana*) and dwarf wedgemussel (*Alasmidonta heterodon*) are federally and state endangered species that occur in the upper Tar and Neuse rivers, respectively (<http://www.ncwildlife.org>, April 2004). Since these species are highly sensitive to water quality and habitat degradation, freshwater mussels are often considered an excellent early biological indicator of freshwater stream condition.

Existing management measures

The majority of the management measures discussed in the water column and other habitat sections would also benefit soft bottom by reducing loading of point and non-point pollutants. Recently, several actions have been taken regarding beach nourishment and management of intertidal and subtidal ocean soft bottom habitat. The North Carolina General Assembly enacted House Bill 1840 in the 2000 Session, which required DENR to prepare a Beach Management Plan (DENR 2000b) and make recommendations on several related policy issues. This plan was to be completed by April 2001, although no funding was allocated for this task. *Completion of a beach management plan using the best scientifically based information could be helpful in directing beach nourishment activities in a manner that minimizes impacts to the soft bottom community.*

In addition, the Legislative Research Commission studied the cost, need, and feasibility of beach nourishment, and submitted a report to the 2001 Session of the General Assembly on Coastal Beach Movement, Beach Renourishment, and Storm Mitigation as mandated by the 1999 General Assembly (Legislative Research Commission 2001). The focus of this report was on economics more than environmental impacts, however. As impacts from beach nourishment are increasingly documented and the magnitude of this activity increases, the scientific community has expressed concern regarding the long-term consequences to fish habitat. An environmental forum on beach nourishment was held in April 2001 by the North Carolina Coastal Federation to compile information and knowledge of scientists on beach nourishment and associated impacts to the marine and estuarine environment. In 2000, the MFC adopted a beach nourishment policy that provides specific suggestions and guidance to agencies concerning effects of beach nourishment on fisheries stocks and the habitats on which they depend. Policies call for avoidance, minimization, and mitigation for impacts that do occur, monitoring to document pre- and post- conditions, and assessments that take cumulative impacts into account (Appendix K).

In July 2001, the USFWS designated 1,798 miles of intertidal and supratidal (dry) beaches and dunes to the mean low water (MLW) in eight states as Critical Habitat for the wintering population of piping plover (*Charadrius melodus*). Critical Habitat is defined in the Endangered Species Act as a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection (<http://endangered.fws.gov/listing/critical_habitat.pdf>). This may include suitable habitat that is not currently occupied by the species but is needed for its recovery, thereby providing more habitat protection. Federal agencies are required to consult with the USFWS to ensure that any federal actions do not adversely modify Critical Habitat functions, including areas not currently occupied by a designated species. This action, by providing protection to intertidal benthos, which plovers feed on, should also benefit benthic feeding surf fish. There are 18 designated areas in North Carolina, primarily inlet systems and adjacent shoals and spits. Refer to website (<http://plover.fws.gov>) for maps of the designated areas.

Another federal initiative that provides resource protection to ocean soft bottom habitat is the Coastal Barrier Resources Act (COBRA), that began in 1982. The COBRA Act (16 U.S.C. ээ 3501-3510) generally restricts federal spending for establishment or expansion of infrastructure (roads, wastewater systems) and disaster relief funds in high-risk coastal areas. It also prohibits federally guaranteed low-cost flood insurance from designated areas that might contribute to development on designated undeveloped barrier islands. The restrictions are intended to discourage unwise development in ecologically sensitive areas. In North Carolina, some of the areas requesting storm damage reduction projects (portions of Cape Hatteras and North Topsail Beach) are located within federally designated Coastal Barrier Resources Act (COBRA) sites (Map 6.3 a-c). A recent report to Congress estimated that the COBRA has saved taxpayers approximately $1.3 billion, and that about $200 million in disaster relief funds could be saved by 2050 (<http://www.fws.gov/cep/cbrtable.html>, 2003). This act demonstrates an innovative strategy to protect undeveloped natural resources through economic disincentives, while imposing no new regulations on how an individual may develop their land. *Funding for beach nourishment in designated COBRA areas should not be supported by state or local funds.*

6.5 SUMMARY OF SOFT BOTTOM CHAPTER

Soft bottom habitat is the unvegetated bottom sediment in all coastal systems, and includes features such as inlets, shoals, channel bottoms, intertidal ocean beaches, and cape shoals. Soft bottom plays a key role in primary productivity in shallow estuarine and marine systems. This habitat strongly influences the water column through dynamic cycling processes, storing and releasing nutrients and chemicals over time. Other ecosystem functions of soft bottom include the reduction of physically destructive storm effects on oceanfront beaches, and providing sand sources for barrier island and inlet migration. Soft bottom habitat is particularly important as a foraging area for all size ranges of bottom feeding fish and invertebrates, such as blue crabs, shrimp, flounders, striped mullet, spot, croaker, and kingfish. Burrowing mollusks (i.e., hard clams, coquina clams), flatfishes (i.e., southern flounder, hogchoker) and baitfish (i.e., striped mullet) are highly associated with shallow soft bottom, while larger benthic feeding predators (i.e., weakfish, coastal sharks, sturgeons) typically utilize deeper soft bottom areas. Valued fishery species that depend on healthy soft bottom habitat include hard clams, shrimp, blue crabs, southern flounder, Atlantic croaker, striped mullet, kingfish, and spot. Of these, the DMF stock status of Atlantic and shortnose sturgeons, southern flounder, and coastal sharks was Overfished. Striped mullet and Atlantic croaker were listed as Concern. The Atlantic sturgeon, which is classified as Overfished, has been under a fishing moratorium since 1991 but has not shown signs of recovery. Coastal inlets have been federally designated as Habitat Areas of Particular Concern for blue crab, estuarine-dependent snapper and grouper, penaeid shrimp, and red drum.

Inadequate data are available to clearly indicate the current condition of soft bottom habitat. Fortunately this habitat is relatively resistant to a changing environment. This is the most abundant submerged coastal fish habitat, and estuarine acreage of soft bottom has undoubtedly increased over time as shell bottom, SAV, and wetland habitats have declined.

Threats of greatest concern include large-scale alterations such as dredging of productive shallow bottom areas, construction of marinas and docks, bottom dredge and trawl fisheries in estuarine waters, and large-scale beach nourishment. Depletion of oxygen and toxic contamination of bottom sediments are the major water quality concerns since those conditions can cause mortality or poor recruitment of benthic invertebrates, which in turn can affect food availability for numerous benthic feeding invertebrates and fish. Therefore, minimizing dredging of productive shallow bottom, properly managing beach nourishment to maintain healthy benthic communities in the surf zone, and reductions in nutrient and toxin loading in all coastal waters are the primary management needs for soft bottom.

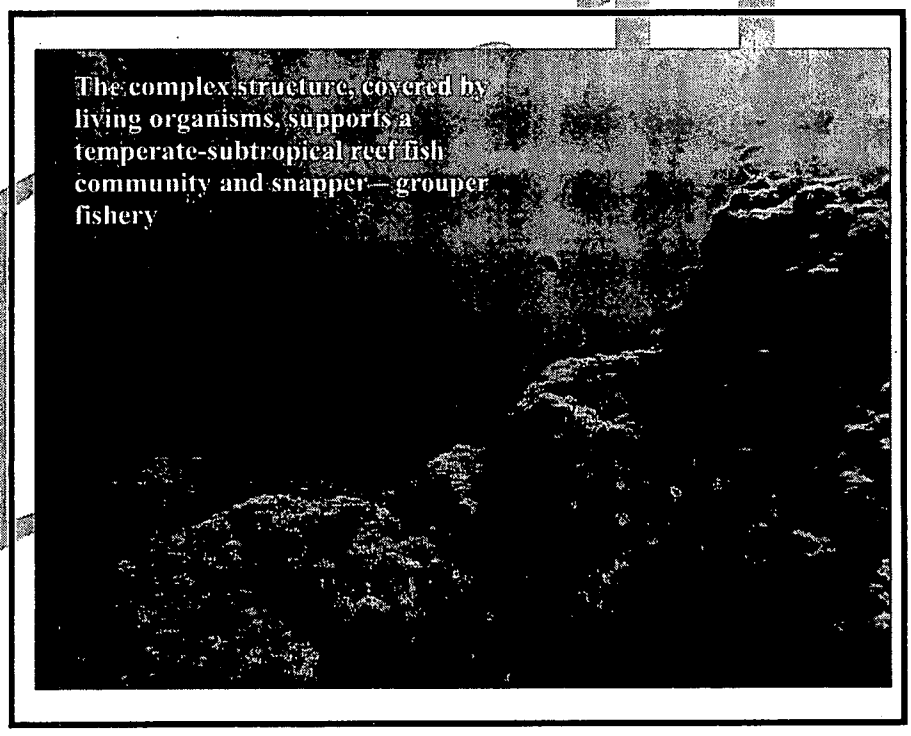
CHAPTER 7. HARD BOTTOM

7.1. DESCRIPTION AND DISTRIBUTION

Definition

Hard bottom refers to a classification of coral communities that occur in temperate, subtropical, and tropical regions that lack the coral diversity, density, and reef development of other types of coral communities (SAFMC 1998a). For the purposes of the CHPP, hard bottom habitat is defined as "exposed areas of rock or consolidated sediments, distinguished from surrounding unconsolidated sediments, which may or may not be characterized by a thin veneer of live or dead biota, generally located in the ocean rather than in the estuarine system."

Man-made structures, such as artificial reefs, wrecks, and jetties, provide additional suitable substrate for development of hard bottom communities. Artificial reefs are structures constructed or placed in waters for the purpose of enhancing fishery resources and providing opportunities for commercial and recreational fisheries. Although the purpose of artificial reef placement is primarily fishery enhancement, colonization of the structures by marine life results in establishment of hard bottom habitat. Vessels that have run aground or sunk and remain on the seafloor can also provide a base for hard bottom communities. These sites are separate from the DMF-managed artificial reef sites.



Description

Natural hard bottom varies in topographic relief from a relatively flat, smooth surface to a scarped ledge having up to 10 m of vertical, sloped, or stepped relief. The exposed areas of rock outcrop or relic reef are colonized to a varying extent by algae, sponges, soft coral, hard coral, bryozoans, polychaetes, and tunicates, which in turn support a large diversity of fish (SAFMC 1998a). Hard bottom is also referred to as "live rock" or "live bottom" because of the abundance of live plants and invertebrates that typically attach to or bore into hard substrate. Erosion of the hard substrate through the long-term actions of

colonizing organisms results in overhanging hard bottom ledges and undercut sloped scarps (Riggs et al. 1995). Rock outcrops, particularly those with low relief, can become buried and unburied by the natural processes of sand movement across the seafloor (SEAMAP-SA 2001). When hard substrate is exposed, a live bottom community may develop on the hard surfaces and persist for many years, later becoming covered by varying thicknesses of sand (SEAMAP-SA 2001). Areas of compacted or sheered mud and sediment also function as consolidated hard bottom (Riggs et al. 1995).

Artificial reefs can be constructed of many different materials. In North Carolina, surplus vessels, steel boxcars, concrete pipe, concrete rubble, boat molds, tires, and surplus military aircraft have been used for artificial reefs. In addition, concrete structures specifically designed and constructed to provide complex habitat (domes, igloos) are used by DMF. In total, artificial reefs provide roughly 2.75 million ft^2 (47 acres) of hard surface area (DMF 1995). This area is equivalent to approximately 2% of the natural hard bottom occurring in Raleigh and Onslow bays. The DMF Artificial Reef Program is responsible for deployment and maintenance of the sites, following the guidelines of the DMF Artificial Reef Master Plan (DMF 1988). In addition to the DMF's artificial reefs, the U.S. Army Corps of Engineers (COE) constructed a large artificial reef off the Cape Fear River, known as the Wilmington Offshore Fishery Enhancement Structure, using rock dredged during deepening of the Cape Fear River shipping channel. Comprised of approximately 800 barge-loads of rock and rubble piled in rows, this structure is currently being disrupted by relocation of the Cape Fear River shipping channel. The North Carolina Department of Cultural Resources, Underwater Archeology Unit, estimates there are more than 1,000 sunken vessels along the North Carolina coast dating from the days of the earliest European explorers to the present (<http://www.arch.dcr.state.nc.us/UW-LIGIT.HTM>, 2003). Documented wrecks include World War II German U-boats, gunboats, tankers, freighters, barges, and wooden and iron-hulled steamers. The abundance of shipwrecks off the North Carolina coast provides additional structure available as hard bottom habitat.

Jetties are man-made structures consisting of large boulders placed perpendicular to the shoreline, usually near inlets, for the primary purpose of stabilizing navigational channels. Because jetties emerge above the water line, they support both intertidal and subtidal hard bottom communities. Groins are similar to jetties, but are generally smaller. They may be constructed to stabilize a marina entrance or navigational channel or used as an erosion control device to trap sand and stabilize the shoreline. Community composition and fish utilization of jetties were described in Hay and Sutherland (1988) and are discussed in section 7.2, Ecological role and functions.

Habitat requirements

The primary requirement for this habitat is exposed hard substrate. Bottom water temperatures at hard bottom habitats in the ocean off North Carolina range from approximately 11 to 27° C. Salinity is generally around 35 ppt with little fluctuation. The composition of invertebrate, algal, and fish communities varies with temperature and depth. Although hard bottom is similar to other coral reef communities, the hard bottom community in warm-temperate regions such as North Carolina is physically stressed by changes in water masses and seasonal fluctuations in water temperature and light penetration (Kirby-Smith 1989). Because of this stress, hard coral and reef fish abundance and diversity in temperate hard bottom are limited and often vary by season.

Distribution

Hard bottom is the most widely distributed coral community in the South Atlantic Bight. It occurs in both warm-temperate and tropical areas, although it is less extensive in the northern end of its range (North Carolina). Along the south Atlantic states, hard bottom ranges from the shoreline and nearshore (within the state's three-mile jurisdictional limit) to beyond the continental shelf edge (>200 m deep). It tends to occur in clusters across the shelf in specific areas (SEAMAP-SA 2001). Estimates of the percent cover of hard bottom vary greatly along the south Atlantic coast between Cape Canaveral and Cape Hatteras.

From Cape Hatteras to Cape Fear, it was estimated that approximately 14% (roughly 504,095 acres) of the bottom between 27 and 101 m water depth consisted of hard bottom; between Cape Fear and Cape Canaveral, 30% (roughly 1,829,321 acres) of the seafloor was hard bottom (Parker et al. 1983). Approximately 7–10% of the hard bottom habitat is estimated to be one meter or more in relief (Parker et al. 1983).

Hard bottom mapping

In 1985, the Southeast Area Monitoring and Assessment Program—South Atlantic (SEAMAP-SA) began a large-scale initiative to identify and map all known hard bottom and coral reef areas in the South Atlantic Bight. A final report and ArcView GIS CD were completed in 1998 and updated in 2001 (SEAMAP-SA 2001). The majority of the data used to identify hard bottom was based the relative presence of indicator species in traps or trawls or on sidescan sonar records (73%). The SEAMAP Bottom Mapping Workgroup identified 177 South Atlantic Bight reef species that indicate reef habitat. The remaining data came from video and diver observations. The majority of identified sites was located in federal waters off North Carolina (> three nautical miles (nm) from shore). Because of the ephemeral nature of low-relief hard bottoms (uncovered and covered by storm-induced shifting sands) and the difficulty of distinguishing soft bottom from low-relief hard bottom using seismic data, the amount of hard bottom habitat identified in this program was most likely an underestimate (SEAMAP-SA 2001).

Hard bottom and artificial reef sites identified by SEAMAP in both state and federal waters are shown in Map 7.1, along with some of the known wrecks. Hard bottom outcrops are most concentrated in Onslow and Long bays. In federal waters, concentrations occur offshore between Shallotte Inlet and the Cape Fear River. In Onslow Bay, hard bottom is most concentrated from Frying Pan Shoals north to Masonboro Inlet, from New Topsail Inlet to Brown's Inlet, and from Bogue Inlet east to Cape Lookout Shoals. In Raleigh Bay, there are two concentrations of hard bottom – one east of Lookout Shoals and another south of Diamond Shoals. Within North Carolina state territorial waters, using point data, the SEAMAP database identified 19 natural hard bottom sites and 16 possible hard bottom sites. In addition, line data from trawls identified 29 hard bottom sites and 59 possible sites.[1]

A follow-up study compiling hard bottom locations in the nearshore ocean waters of North Carolina identified additional sites not included in the SEAMAP-SA database (Map 7.1, Table 7.1) (Moser and Taylor 1995). The study relied on surveys of researchers, dive professionals, and fishermen. Some of these sites may be duplicates of those identified by SEAMAP-SA, due to different sources and slightly different coordinates. A total of 198 hard bottom positions was identified; some were point data, while others represented transects or areas. Over 92% of the identified hard bottom in North Carolina waters are south of Cape Lookout, particularly in the southern half of Onslow Bay and in northern Long Bay. Concentrations of hard bottom occur seaward of inlets, including Shallotte, Lockwood's Folly, New, Carolina Beach, Masonboro, New Topsail, New River and Bogue inlets. There are outcrops of moderate-to-high relief in shallow water near the shoals of Cape Fear and Cape Lookout. Moser and Taylor (1995) estimated that the majority of the bottom in state territorial waters from 1) mid-Onslow Beach to south of New Inlet and 2) the area from Yaupon Beach west to Tubbs Inlet is comprised of hard bottom that is covered with a thin layer of sand.

[1] The lengths of the trawl lines vary, and some lines may actually represent several transects of one area. Similarly, some hard bottom lines may overlap with hard bottom points.

Table 7.1 Hard bottom and possible hard bottom locations in North Carolina by coastal bay. *[Source: Point and line data identified by SEAMAP-SA (2001).]*

Bottom Type	Long Bay	Onslow Bay	Raleigh Bay	North of Hatteras	Total
Hard bottom (point)	2 (19)	14 (58)	1 (4)	2 (3)	19 (86)
Hard bottom (line)	3 (6)	25 (39)	1 (2)	0 (2)	29 (49)
Possible hard bottom (point)	1	8	3	4	16
Possible hard bottom (line)	5	37	12	5	59
Total	11 (25)	84 (97)	17 (6)	11 (5)	123 (135)

Results from Moser and Taylor (1995) in parentheses.

Twenty sites were reported as high-profile relief, defined by Moser and Taylor (1995) as vertical relief greater than two meters. Two of these sites, one off Carolina Beach and one off New River, are extensive in both area and topographic relief; these areas are particularly close to shore, making them more vulnerable to land-based, fishing, and boating-related impacts. A unique intertidal and subtidal coquina rock outcrop extends from the beach into the surf zone at Fort Fisher. This unique habitat supports a diversity of organisms such as starfish, anemones, sea urchins, crabs, octopi, and numerous fish species.

Distribution of man-made hard bottom

There are 11 artificial reefs of varying construction located in North Carolina State ocean waters, 28 in federal ocean waters (Map 7.1), and seven in estuarine waters. The estuarine artificial reefs are located in Pamlico Sound, Albemarle Sound, Neuse River, and Pamlico River. The artificial reef program periodically adds material to the 39 existing ocean sites, rather than creating new reefs. Gentile (1992) listed 46 documented wrecks in North Carolina waters south of Hatteras Inlet. The majority of the wrecks is located northeast and west of the mouth of the Cape Fear River (Map 7.1). There are many more wrecks in federal waters, with concentrations around the three cape shoals. There are also two jetty systems and three groin systems along the ocean shoreline. The groins are located on the south side of Oregon Inlet, off the former site of the Cape Hatteras Lighthouse, and at the west side of Beaufort Inlet. There is a single jetty at the west side of Cape Lookout; Masonboro Inlet has jetties on both sides–one attached to Wrightsville Beach and the other attached to Masonboro Island. The Little River Inlet, which is the state boundary between North and South Carolina, also has a dual jetty system, but both structures are located in South Carolina. There are also numerous small groins and jetty systems in estuarine waters, but these features have not been mapped.

For the purposes of this document, estuarine shell bottom (e.g., oyster reefs, beds, bars) is not categorized as hard bottom habitat. Although technically a "hard" substrate that shares some characteristics with hard bottom (e.g., three-dimensional structure), shell bottom differs in its formation, spatial distribution, function and species composition from those of oceanic hard bottom; it is classified as a distinct habitat type. In addition, shell bottom can be either inter- or subtidal, whereas hard bottom is typically subtidal (with the single exception of the exposed coquina outcrops near Fort Fisher).

7.2. ECOLOGICAL ROLE AND FUNCTIONS

Productivity

Exposed hard substrate (whether rock outcrops, jetties, artificial materials, or semi-compacted sediments) provides surface area for colonization by invertebrates and algae. Hard substrate with vertical relief or irregular surface areas provides more complex habitat, allowing a greater variety of species to coexist (Wenner et al. 1984). This "live bottom" structure, in turn, provides a source of abundant food and protective cover for numerous fishes. These areas may be quite small and isolated and have been considered oases of productivity surrounded by less productive unconsolidated ocean bottom (SAFMC 1998a). The extent and diversity of colonization vary among sites due to topography, habitat diversity,

currents, light availability, and location on the shelf. Studies that have documented the composition and diversity of the communities on hard bottom in North Carolina include MacIntyre and Pilkey (1969), Schneider (1976), Peckol and Searles (1984), Kirby-Smith (1989), and COE (1992). Most of the locations examined in these studies were located beyond the three-mile state boundary.

The dominant colonizing organisms on hard bottom in North Carolina are macroalgae (Peckol and Searles 1984), ranging from 10 to 70% of the biotic cover, and varying among seasons and years. Perennial and crustose brown and red algae were the dominant algal forms, including *Lobophora variegata*, *Lithophyllum subtenellum*, *Zonaria tournefortii*, and *Gracilaria mammillaris*. In nearshore waters (< one nm from shore), between Rich Inlet and Brown's Inlet, large amounts of seaweed grow on and between hard bottom areas during the summer. The algae consist of several types and species, including the brown alga, *Sargassum filipendula* and *Dictyopteris membranacea,* and the red algae, *Halymenia* sp. and *Gracilaria* sp. (DMF 2001). Sargassum *(S. filipendula)* is common in nearshore and offshore waters, and on jetties. Hay and Sutherland (1988) documented several other species on jetties. Roughly 150 species of macroalgae were identified on hard bottom in North Carolina; the majority was red algae (Rhodophyta) (Schneider 1976). Onslow Bay had a higher diversity of species, which was attributed to more available hard substrate (Schneider 1976). The shallow inshore flora consisted of a large component of northern-distributed species, while offshore areas supported more tropical flora. Offshore areas had the greatest abundance of macroalgae, due to the high proportion of suitable substrate, greater relief on the shelf break, and mild water temperatures throughout the year. Of the offshore species, 66% were at their northern limit of distribution in Onslow Bay, and 2% were at their known southern distributional limit (Schneider 1976). The latter include *Arthrocladia villosa*, *Gigartina stellata*, and *Polysiphonia harveyi*. The presence of macroalgae from the shoreline to beyond the shelf break indicates that light and nutrient availability do not limit primary production on hard bottom off North Carolina (Cahoon and Cooke 1992).

Community structure

Non-mobile, attached invertebrates accounted for 10% or less of the biotic cover on hard bottom off North Carolina (Peckol and Searles 1984). The most abundant non-mobile invertebrates were the soft corals, *Titanideum frauenfeldii* and *Telesto fruticulosa,* and the hard coral, *Oculina arbuscula.* Sea urchins (*Arbacia punctulata* and *Lytechinus variegatus*) were the most common mobile invertebrates. Species composition of invertebrates occurring at hard bottom sites in South Carolina and Georgia were studied by Wenner et al. (1984). Study results using dredge and trawl samples showed that sponges, bryozoans, corals and anemones[2] dominated the large macroinvertebrate collection in terms of numbers and species diversity during all seasons. Sponges were the most important invertebrate group overall on the inner shelf, comprising 60–78% of the total biomass. Tunicates, anthozoans, and mollusks also contributed substantially (Wenner et al. 1984). Species characteristic of the inner shelf sites included the sponges, *Homaxinella waltonsmithi, Spheciospongia vesparium, Cliona caribbaea*, and *Halichondria bowerbanki*; the echinoderms, variegated urchin (*Lytechinus variegatus*), purple sea urchin (*Arbacia punctuata*), *Encope michelini*, and *Ocnus pygmaeus*; the bryozoan, *Membranipora tenuis*; and the decapod crustacean, *Synalpheus minus*. Grab samples of small invertebrates showed that polychaetes were the most diverse and abundant group, followed by mollusks, and amphipods[3] (Wenner et al. 1984).

Kirby-Smith (1989) studied hard bottom communities at nearshore and offshore reefs in North Carolina. Community structure varied with season, depth, and distance from the shelf edge. Diversity and abundance of invertebrates were greater in the spring and fall than in winter and summer, attributed to spring and fall plankton blooms. The inner shelf sites, in approximately 16–27 m water depths, had somewhat lower diversity than mid- or outer shelf sites. Mollusks, followed by polychaetes, and then

[2] sponges (89 Porifera taxa), bryozoans (91 Bryozoa taxa) and corals and anemones (70 Cnidaria taxa)

[3] polychaetes (285 species, 72% of total individuals); mollusks (251 species, 4.3% of total individuals); and amphipods (100 species, 13% of total individuals)

amphipods were dominant in the number of observed species.

Due to cooler water temperatures and greater temperature fluctuations, the species composition of hard bottom communities in nearshore waters is less tropical in nature compared to that farther offshore or south of North Carolina (Kirby-Smith 1989). Furthermore, at natural and artificial reefs in Onslow Bay, seaweed species outcompeted a hard coral (*Oculina arbuscula*), limiting its growth and recruitment and largely restricting its distribution to deeper, poorly lit habitats via competitive exclusion (Miller and Hay 1996). Because of these conditions, hard bottom in North Carolina's state territorial sea is colonized by hard and soft corals to a lesser extent than offshore or more southern areas. Two species of reef building corals that have been documented on North Carolina hard bottom are *Solenastrea hyades* and *Siderastrea siderea*. These species occurred on rock outcrops at depths of 20 to 26 m in Onslow Bay approximately 32 km offshore (Macintyre and Pilkey 1969). Other species of coral reported for North and South Carolina include the hard corals, ivory bush coral (*Oculina arbuscula*), *Oculina varicosa*, *Astrangia danae, Phyllangia americana, Balanophyllia floridana*, and the soft corals, sea whip (*Leptogorgia virgulata*), *Telesto* spp., *Lophogorgia* spp., *Titanideum frauenfeldii,* and *Muricea pendula* (Hay and Sutherland 1988; Wenner et al. 1984).

Ecosystem enhancement

In addition to providing habitat for an abundance of reef organisms and fish, hard bottoms, through bioerosion, are a source of sand production for sediment-starved sections of the continental shelf, such as Onslow and Long bays. Riggs et al. (1995) described three primary groups of bioeroders: rock boring bivalves, burrowing shrimp, and macroalgae. These animals and plants tend to occur in or on hard bottom of different hardnesses and slopes. Some species, like the rock boring bivalve *Jouanettia quillingi* and burrowing shrimp *Upogebia* sp., occur on muddy sandstones, while macroalgae tend to colonize Pleistocene limestones. The larvae of rock boring bivalves erode rock by excavating a hole chemically (through secretion of acid) or mechanically (through abrasion from their hard shell). Over time, multiple tunnels from clams eventually weaken the rock until chunks break off, leaving a fresh rock surface for more clam larvae to settle on and bore into. Macroalgae erode rock when their roots (holdfasts) are torn off the rock surface by storms and strong water currents, carrying away small pieces of rock. The decomposition of calcareous macroalgae plant material also produces sediment. Rates of sediment production from bioerosion increase with increasing softness of rock substrate, varying from 5.5 kg/m^2/yr on vertical and sloped Miocene mudstone hard bottom, to 0.4 kg/m^2/yr on vertical and sloped Pleistocene limestone, and 0.03 kg/m^2/yr on flat Plio-Pleistocene limestone. These processes also enhance the structural complexity of the hard bottom outcrops, which promotes diversity of fish habitat within the reef (Riggs et al. 1995).

Fish utilization of natural hard bottom

Because of their structural complexity, more permanent nature, and high functional diversity, hard bottom areas of relatively high relief are particularly important to a variety of fish and invertebrate species. Fish comprise a major portion of the animal biomass on hard bottom, and they are an important component of the overall trophic structure (Jaap 1984). Numerous studies have examined fish assemblages on natural and artificial reef habitats in North Carolina (Huntsman and Manooch 1978; Miller and Richards 1980; Grimes et al. 1982; Lindquist et al. 1989; Potts and Hulbert 1994; Parker and Dixon 1998). With the exception of Hay and Sutherland (1988), who described fish utilization at jetties in North Carolina, all of these studies, including those at the inner shelf, were conducted seaward of state territorial waters. *Fish studies specific to nearshore hard bottom (within state territorial waters) are needed to better understand the dependence of fish species on this habitat.*

Natural hard bottoms off the Carolina coasts support large populations of offshore reef fish, temperate, and coastal pelagic species. In one study along the North and South Carolina coasts, 47 tropical and subtropical resident reef fish species were found on inshore hard bottom (<18 m water depth), and almost

twice as many occurred further offshore (18–110 m water depth). The fauna of hard bottom is characterized by wrasses, damselfish, snappers, grunts, parrotfish, and sea basses. Inshore hard bottom communities support large numbers of more temperate fish species, such as black sea bass (*Centropristis striata*), spottail pinfish (*Diplodus holbrookii*), and estuarine-dependent migratory species (Huntsman and Manooch 1978). A list of species reported for North and South Carolina inshore hard bottom is provided in Table 7.2.

Water temperature and topography are the most important factors in determining use of habitat by warm-temperate and tropical hard bottom species (Wenner et al. 1984; SAFMC 1998a). Temperatures less than 12° C may result in the death of some tropical fish and invertebrate species. Lindquist et al. (1989) reported 32 species at inner shelf hard bottom sites in North Carolina, approximately five miles from shore. Commonly occurring and numerically abundant species for both natural and artificial reefs were, in order of decreasing abundance:

- round scad (Decapterus punctatus)
- tomtate (Haemulon aurolineatum)
- spottail pinfish (*Diplodus holbrookii*)
- black sea bass (Centropristis striata)
- slippery dick (Halichoeres bivittatus)

Other common species included scup (*Stenotomus chrysops*), juvenile grunts, pigfish (*Orthopristis chrysoptera*), cubbyu (*Equetus umbrosus*), and belted sandfish (*Serranus subligarius*). Fish composition varied due to seasonal inshore migrations of tropical and subtropical species, fishing pressure, and microhabitat differences.

Draft

Table 7.2. Fishes occurring at inshore hard bottom in North Carolina and South Carolina coastal waters. *[Sources: Grimes et al. 1982; Powell and Robins 1998; DMF, unpub. data]*

Family	Scientific name	Common name
Carcharhinidae	*Carcharhinus falciformis*	Silky shark
Muraenidae	*Gymnothorax nigromarginatus*	Blackedge moray
Ophichthidae	*Ophichthus ocellatus*	Palespotted eel
Engraulidae	*Anchoa* sp.	Anchovy
Synodontidae	*Synodus foetens*	Inshore lizardfish
	Trachinocephalus myops	Snakefish
Batrachoididae	*Opsanus pardus*	Leopard toadfish
Antennaridae	*Antennarius ocellatus*	Ocellated frogfish
Gadidae	*Urophycis earlii*	Carolina hake
Ophidiidae	*Rissola marginata*	Striped cusk-eel
Sygnathidae	*Hippocampus erectus*	Lined seahorse
	Sygnathus sp.	Pipefish
Serranidae	*Centropristis ocyurus*	Bank sea bass
	C. striata	Black sea bass
	Dermatolepis inermis	Marbled grouper
	Diplectrum formosum	Sand perch
	Epinephelus adscensionis	Rock hind
	E. drummondhayi	Speckled hind
	E. morio	Red grouper
	E. fulva	Coney
	E. guttatus	Red hind
	Mycteroperca microlepis	Gag
	M. phenax	Scamp
	M. venenosa	Yellowfin grouper
	Petrometopon cruenatatum	Graysby
	Serranus subligarius	Belted sandfish
Grammistidae	*Rypticus saponaceous*	Greater soapfish
Priacanthidae	*Pristigenys alta*	Short bigeye
	Priacanthus creuntatus	Glasseye snapper
Apogonidae	*Apogon pseudomaculatus*	Twospot cardinalfish
Pomatomidae	*Pomatomus saltatrix*	Bluefish
Carangidae	*Alectis crinitus*	African pompano
	Caranx ruber	Bar jack
Lutjanidae	*Lutjanus analis*	Mutton snapper
	L. campechanus	Red snapper
	L. griseus	Gray snapper
	Decapterus punctatus	Round scad
Haemulidae	*Haemulon aurolinearum*	Tomtate
	H. plumieri	White grunt
	Orthpristis chrysoptera	Pigfish
Sparidae	*Diplodus holbrookii*	Spottail pinfish
	Archosargus probatocephalus	Sheepshead
	Calamus leucosteus	Whitebone porgy
	Stenotomus chrysops	Scup
Sciaenidae	*Equetus umbrosus*	Cubbyu
	Cynoscion regalis	Weakfish
Labridae	*Haliochores bivittatus*	Slippery dick
Ephippidae	*Chaetodipterus faber*	Atlantic spadefish
Clinidae	*Paraclinus* sp.	Blennies
Gobiidae	*Ioglossus calliurus*	Blue goby
Bothidae	*Paralichthys dentatus*	Summer flounder
	Paralichthys lethostigma	Southern flounder

In general, most reef fish are carnivores (Jaap 1984). Benthic invertebrates are therefore very important as energy assimilators and food sources for reef fish (Jaap 1984). A partial list of the most important fish species that utilize hard bottom in North Carolina's state territorial waters and the function the habitat provides is given in Table 7.3. Several of the reef fish species are overfished or there is concern about their viability as a fishery resource (DMF 2003).

Table 7.3. Habitat utilization, stock status, and use of important fish species that occupy hard bottom areas in North Carolina's nearshore ocean waters.

Species	Functions[1]					Fishery[2]	Stock status[3]
	Refuge	Spawning	Nursery	Foraging	Corridor

Refuge and foraging

Hard bottom provides protective cover and foraging areas for an abundance of organisms, supporting high fish productivity. Nearshore hard bottom habitats can support over thirty times as many individuals per transect as natural sand habitats (Lindeman 1997). Consequently, natural reefs can sustain greater fish

stocks (270 to 5,279 kg/ha) compared to non-reef open shelf bottom (6.3 to 46.3 kg/ha) (Huntsman 1979). In general, natural and artificial reefs support similar fish species assemblages (Ambrose and Swarbrick 1989). The abundance of fish on hard bottom and artificial reefs is related to the amount and type of structural complexity of the reef (Potts and Hulbert 1994; Carr and Hixon 1997). Rocky structures that have more available complex space resources consistently supported a more abundant and diverse resident fish community than less complex structures. In addition, multiple small hard bottom areas surrounded by sand habitat supported greater fish abundance and diversity than one large area of equal material, suggesting the importance of habitat variety to overall ecosystem quality (Bohnsack et al. 1994; Auster and Langton 1999). This research suggests that artificial refugia would be beneficial for enhancement of fish productivity and ecosystem value. An artificial refugia site is an artificial reef that is designated as a no-take area, to provide unfished habitat to aid in stock recovery, conduct research, and test effectiveness of enforcement. *Construction of artificial refugia (no-take artificial reefs) or designation of existing artificial reefs as refugia (no-take, Marine Protected Areas) should be considered to enhance fisheries productivity.*

Spawning

Hard bottom provides not only refuge and foraging areas, but also spawning areas. Most reef fish spawn in aggregations in the water column above the reef, and the eggs remain planktonic during development (Jaap 1984). The timing of egg release is often triggered by dusk, night, or the tides, probably to reduce risk from predation. Nearshore hard bottom has been identified as a spawning site for some reef species. Species known to spawn on nearshore hard bottom include black sea bass (*Centropristis striata*) and sand perch (*Diplectrum formosum*) between January and June (Powell and Robins 1998). Sheepshead (*Archosargus probatocephalus*), Atlantic spadefish (*Chaetodipterus faber*), seaweed blenny (*Parablennius marmoreus*), inshore lizardfish (*Synodus foetens*), and several species of damselfish, wrasses, and gobies (*Loglossus calliurus* and others) are also thought to spawn on inshore hard bottom (F. Rohde, DMF, pers. com., 2001). *More research is needed concerning spawning on, and recruitment to, nearshore hard bottom to understand the importance of this habitat and document trends in fish utilization.*

Nursery

Nearshore and inner shelf hard bottom areas serve as important settlement and nursery habitat for immigrating larvae of many important fisheries species. Powell and Robbins (1998) collected larvae from 22 reef-associated families adjacent to hard bottom habitat in Onslow Bay. Planehead filefish, *Monacanthus hispidus*; the blenny, *Parablennius marmoreus*; the goby, *Loglossus calliurus*; tomtate; white grunt; snappers including vermilion snapper, *Rhomboplites aurorubens*; black sea bass; bank sea bass; sand perch; spottail pinfish; and whitebone porgy were commonly collected. These species are thought to have been spawned in Onslow Bay in somewhat deeper water and recruited locally to nearshore hard bottom (Powell and Robins 1998). Additional species that are not generally reef-associated were also collected adjacent to hard bottom, including estuarine-dependent and oceanic species. It is unclear how planktonic larvae recruit to hard bottom habitat, except that recruitment is dependent on water circulation patterns transporting larvae to suitable habitat (Jaap 1984). Hard bottom habitat with vertical relief provides a variety of microhabitats, allowing a diversity of fish to recruit to the structure. Higher food availability in structure-rich hard bottoms, as well as properly managed artificial reefs, may result in increased growth rates, as well as increased survival.

Nearshore hard bottom also serves as intermediate nursery habitat for late juveniles emigrating out of the estuaries (Lindeman and Snyder 1999). In North Carolina, this group of fishes includes black sea bass, gag, red grouper, sheepshead, Atlantic spadefish, bank sea bass, and gray snapper, which are estuarine-dependent as early juveniles, moving offshore to hard bottom habitat as older juveniles. Juvenile red snapper and mutton snapper have also been documented in North Carolina's estuaries to a lesser extent (DMF, unpub. data). Species migrating offshore benefit from structure-rich hard bottom by using it for

refuge from predators and foraging on the high abundance of invertebrates and macroalgae. Lindeman and Snyder (1999) found that over 80% of the individual fish at hard bottom sites on the southeast coast of Florida were early life stages. The study documented more than 20 species of newly settled stages, including several species of grunts and snappers. In North Carolina, the patchy distribution and limited extent of hard bottom suggest that habitat availability may limit survival of early stages of reef fish, giving available hard bottom habitat particularly high value (P. Parker, NMFS, pers. com., 2002).

Fish utilization of man-made structures

The composition and density of fish at artificial reefs tend to be similar to those at natural hard bottom sites when occurring in similar environmental conditions (Potts and Hulbert 1994; Bohnsack et al. 1994; Huntsman and Manooch 1978; Miller and Richards 1980). Studies comparing fish utilization of shipwrecks and artificial reefs of various designs found that all structures supported similar species composition (Stephan and Lindquist 1989). Species composition, relative abundance, and catch-per-unit-effort (CPUE) on artificial reef sites are documented periodically by DMF (DMF 1998; DMF 2002). In 1997, an assessment of the effectiveness of differently constructed artificial reefs found species assemblages to be similar on reefs composed of concrete pipes, cans, or domes. However, the assessment also found that CPUE was 71 – 85% greater on natural reefs than nearby artificial reefs (DMF 1996), possibly because natural hard bottom habitat is inherently more complex than artificial structures.

DEMERSAL SPECIES	PELAGIC SPECIES
INSHORE REEFS (< 30 M DEPTH)	**INSHORE REEFS (< 30 M DEPTH)**
▪ Pinfish	▪ Amberjacks
▪ Pigfish	▪ Barracuda
▪ Black sea bass	▪ Bluefish
▪ Longspine porgy	▪ Bonito
▪ Whitebone porgy	▪ Cobia
▪ Tomtate	▪ King mackerel
▪ Tautog	
▪ Atlantic spadefish	**OFFSHORE REEFS (> 30 M DEPTH)**
▪ Sheepshead	▪ Dolphin
▪ Weakfish	▪ Sailfish
▪ Flounders	▪ Wahoo
▪ Spot	▪ Yellowfin tuna
▪ Atlantic croaker

▪ White grunt	
OFFSHORE REEFS (> 30 M DEPTH)	
▪ Groupers	
▪ Porgies	
▪ Triggerfish	
▪ Snappers	

Jetties provide some of the same habitat functions for fishery resources that natural hard bottoms and artificial reefs provide. The hard surface and irregular relief of the rocks provide shelter and food for the colonized plants and animals, which in turn, serve as prey for higher order invertebrates and fishes. Hay and Sutherland (1988) described fish composition at jetties in North Carolina and South Carolina as a subset of those fish found on offshore hard bottoms and estuarine oyster reefs. The majority of fish moved to deeper water in the winter, gradually returning to inshore habitats as waters warmed in spring. The abundance of *Sparidae* species, such as pinfish, spottail pinfish, and sheepshead, was positively correlated with vegetative cover on the hard bottom. Hay and Sutherland (1988) categorized five general fish groups:

- Small cryptic resident fish, such as blennies and gobies;
- Numerically dominant species that migrate offshore in colder months, such as pinfish, spottail pinfish, black sea bass, and pigfish;

- Predatory pelagic species, such as bluefish, and Spanish and king mackerels;
- Fish attracted to jetties during their northerly migration in spring or southerly migration in fall, such as smooth dogfish (*Mustelus canis*); and
- Tropical species that occur as strays during warmer months, such as butterflyfishes (Chaetodontidae) and sergeant majors (*Abudefduf saxatilis*).

Although jetties provide habitat for some fish, the species that utilize them do not require jetties for survival since they are attracted from other existing natural habitats, such as hard bottom and estuarine oyster reefs. Because of impacts of these artificial structures on intertidal beach and water column functions[4], oceanfront jetties should not be considered as a habitat enhancement tool.

7.3. STATUS AND TRENDS

Status of hard bottom habitat

The condition of this habitat is of particular importance to estuarine-dependent snapper-grouper species that utilize North Carolina's shallow hard bottom habitat as "way stations" or protective stopping points as they emigrate offshore to deeper hard bottom. Protection of the shallow hard bottom habitat in state territorial waters is essential for successful protection of the estuarine-dependent snapper-grouper species and the associated fisheries that primarily occur on hard bottom in federal waters. The offshore snapper-grouper fishery is of great importance to North Carolina's commercial and recreational fisheries because of the market value of the fish, the number of recreational participants, and the associated businesses it supports. The snapper-grouper fishery had an annual market value of $3.6 million between 1992 and 2001 (DMF, unpub. data). For the years 1997–2001, DMF and NMFS records show 10,817 trips annually by private and charter boats and another 1,049 by headboats.

Nearshore reefs, although adversely impacted to various degrees by man, are in good condition overall (SAFMC 1998b). Good information exists on the distribution of hard bottom (Moser and Taylor 1995; SEAMAP-SA 2001). However, there is very little information available to evaluate the status and trends of hard bottom habitat in North Carolina state territorial waters. Anecdotal information from fishermen and local residents in New Hanover County suggests that nearshore hard bottom sites in the 1960s and earlier are now completely covered in sand, and that the abundance of fish along the shore and nearshore areas is much reduced.

Status of associated fishery stocks

Reef fish harvested commercially or recreationally are managed collectively as the reef fish complex or Snapper-Grouper management unit. There are 73 species in this complex, including snappers, groupers, sea bass, porgies, triggerfishes, grunts, jacks, and others. Only a portion of these species is found on North Carolina's nearshore hard bottoms. Information is available on the status of many reef fish species through federal, state, and interstate stock assessments. Fishery-dependent data are collected on reef fish by DMF's Offshore Live Bottom Fishery Program (DMF biological database program 438/448). Fishery-independent status and trends data on reef fish are also available for a portion of North Carolina from the Marine Resources Monitoring, Assessment, and Prediction Program (MARMAP) conducted by the South Carolina Department of Natural Resources. This program has conducted standardized groundfish (bottom fish) surveys since 1973 utilizing a variety of fishing gears. Since 1983, surveys have been conducted using fish traps and long lines from Cape Lookout south to Ft. Pierce, Florida. Sampling occurs on mid-shelf live bottom and shelf-edge reef habitats in water from 16 m to more than 92 m deep. Species composition, fish length, and fish weight are recorded to determine community structure, biomass estimates, distribution, and relative abundance of the more abundant species. In addition, CPUE is calculated for vermilion snapper, red porgy, white grunt, gray triggerfish, and black sea bass (SCDNR,

[4] see Water Column (2.0) and Soft Bottom (6.0) chapters

unpub. data). Although sampling occurs seaward of state waters, this program provides valuable information for state and federal stock assessments of reef fish, including species that utilize nearshore hard bottom and estuarine waters in North Carolina.

Most major South Atlantic reef fish stocks are considered fully utilized or over-utilized (NMFS 2002). Of 73 managed species in the South Atlantic Snapper-Grouper management unit, including black sea bass, 14 species were classified as Overfished in 2001 by the NMFS, nine were not Overfished, and 50 were Unknown (NMFS 2002).[5] Red porgy, speckled hind, red snapper, and snowy grouper are a few of the reef species classified as Overfished that occur in North Carolina.

In North Carolina, the reef fish complex as a whole was classified as "concern" by DMF in 2002 (DMF 2003). For stock status of individual reef species, DMF defers to SAFMC (included in Table 7.3). Of the ten fishery species listed in Table 7.3 that are highly associated with inshore hard bottom in North Carolina, nine stocks have been evaluated and eight of these have been given a stock status by DMF or SAFMC. Half of the stocks were reported as overfished (red porgy, sheepshead, tautog, and black sea bass south of Hatteras), while the other half were viable (gag, tomtate, white grunt, black sea bass north of Hatteras) (Figure 7.1). Gag was upgraded by DMF in 2002 from the overfished category to viable. Black sea bass north of Cape Hatteras was upgraded from overfished to viable, based on the Northeast Fishery Science Center spring survey. Black sea bass south of Cape Hatteras was downgraded to overfished based on the SAFMC stock assessment, which indicated low spawning stock biomass and heavy fishing exploitation. Approximately 74% of black sea bass landed in North Carolina are caught south of Hatteras.

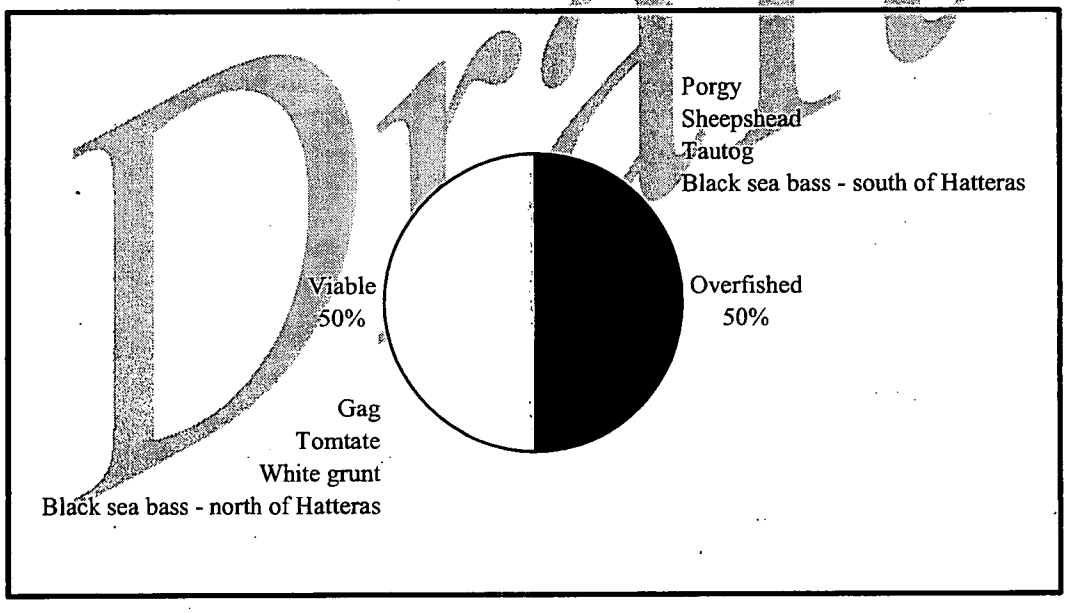

Figure 7.1. Percent of hard bottom associated fish stocks classified as Overfished or Viable in the 2003 DMF Stock Status Report, which includes SAFMC stock assessments of some species in the snapper-grouper complex. No species were reported as Concern or Recovering.

[5] Overfished is defined as "a stock size was below a prescribed biomass threshold" (NMFS 2002) and Unknown is defined as "no recent assessment was conducted or insufficient information about this stock exists to make a determination" (NMFS 2003).

Although most of the overfished species are caught primarily in federal waters, many are highly dependent on the shallow hard bottom habitat in state waters as primary and secondary nursery areas. The status of gag and black sea bass is particularly important because they are highly dependent on nearshore hard bottom and estuarine habitats as primary and secondary nursery areas and for providing migratory corridors as species move offshore as individuals age. The apparent vulnerability of reef species to overfishing is attributed to their long lives, slow growth, ease of capture, large size, and delayed sexual maturity. *The MFC should consider designating inshore hard bottoms (within state territorial seas) as Strategic Habitat Areas because of their importance as secondary nursery habitats and migratory corridors for black sea bass, gag, and other reef fish species.*

Because of concern for the overfished status of major stocks of the snapper-grouper complex and failure of those stocks to adequately recover despite extensive changes in fishing regulations, the SAFMC is considering establishment of Marine Protected Areas (MPAs) in the south Atlantic area. The primary purposes for MPA designation by the Council would be to protect important known grouper spawning aggregations and prevent overfishing, particularly for deepwater species. One deepwater site is currently being considered in federal waters off North Carolina in Onslow Bay, east of Cape Fear. A shallow water site near Cape Lookout has been proposed as an artificial refugia location. An artificial refugia site is an artificial reef that is designated as a no-take area, to provide unfished habitat to aid in stock recovery, to conduct research, and to test effectiveness of enforcement. *Within this area, program sponsors should construct numerous small complex sites surrounded by open areas to mimic natural nearshore hard bottoms and maximize habitat utilization.*

Overfished stocks can be particularly vulnerable to changes in the quantity or quality of habitat. While some research in Florida has indicated that habitat is not limiting and reef fish population is controlled primarily by recruitment success (Bohnsack 1996; Grossman et al. 1997), these studies may not be applicable to North Carolina where hard bottom is much less abundant. In North Carolina, there appears to be a direct relationship between the amount of hard bottom and the number of reef fish. Of the three bays in North Carolina, Onslow Bay has more hard bottom than Long Bay or Raleigh Bay and also has the greatest amount of reef fish (P. Parker, NMFS, pers. com., 2002). This relationship implies that increased habitat quantity would result in more or larger populations of reef fish. *Field experiments using a Before-After-Control-Impact Paired Series (BACIPS) design may be able to compare differences in fish abundance between undisturbed reefs (control sites) and areas with recently-added artificial structure (experimental sites) (Osenberg et al. 2002).*

Hard bottom restoration

Artificial reefs can potentially enhance fish production by increasing foraging, spawning, and refuge habitat (Grossman et al. 1997). However, there is some concern among fishery scientists that the structures may only concentrate available biomass rather than increase regional productivity (Carr and Hixon 1997). Artificial reefs are most effective at increasing production where reef habitat is limiting, when fishing effort is low, and when a large stock reservoir exists (Bohnsack 1996; Grossman et al. 1997). However, the results of studies attempting to determine if habitat is limiting are mixed. Although coral-eating fishes have been shown to decrease in abundance with decreasing live coral coverage, a similar relationship with fish-eating fishes, such as snappers and groupers, has not been observed (Grossman et al. 1997). The latter group is the more common type of reef fish in North Carolina and the primary target of anglers.

Artificial reefs must be properly designed, sited, and managed to successfully increase production of benthic (bottom-dwelling organisms) biomass and fish populations (DMF 1988). If habitat is limiting, artificial reefs that are not marked for fishing exploitation could serve as artificial refugia, providing beneficial habitat functions that could enhance local populations of reef fishes. Also, small complex structures that mimic natural hard bottom may be better for overall recruitment and enhance juvenile habitat and survival, while larger structures may be better for attracting large predators and enhancing

fishing (Bohnsack et al. 1994). One ongoing problem that the DMF has experienced with artificial reefs is the failure of some designs to remain assembled and in position. Early reefs composed of tires have broken apart during storms, and the tires have washed up on beaches and obstructed commercial fishing trawls. More recent artificial reefs constructed of concrete and pipes appear to remain in position as designed (DMF 1995). The DMF Artificial Reef Master Plan provides recommendations for design and siting of artificial reefs (DMF 1988). Some of the recommendations that pertain to habitat enhancement include:

- Materials used should not be toxic to the environment;
- Materials used must be stable and durable;
- Materials used should provide the degree of habitat complexity and profile appropriate for the targeted reef species;
- Artificial reefs should be designed to increase surface area and interstitial space by addition of rock, concrete or other suitable materials to barges and stripped vessels that lack structural complexity;
- Trolling alleys, reef clusters, and reef sanctuaries should be incorporated into reef complex designs;
- Artificial reefs should not be sited where natural hard bottom exists, in high-energy environments, or where traditional commercial fishing activities occur;
- Enhancement of existing artificial reef sites should be a higher priority than construction of new artificial reef sites;
- If artificial reefs are used to replace natural reef habitat that has been damaged or destroyed, they should be designed and constructed to provide proven biologically productive habitat.

High numerical abundance of fish may not necessarily be associated with increased production, survivorship, or species richness. The attraction-production debate regarding artificial reef fish assemblages is not yet resolved (Bohnsack 1989; Pickering and Whitmarsh 1996; Carr and Hixon 1997; Rilov and Benayahu 2000). *Additional research is needed to determine if and to what extent artificial reefs in North Carolina simply concentrate available fish or effectively increase fish biomass.*

7.4. THREATS AND MANAGEMENT NEEDS

Dredging and beach nourishment

In evaluating habitat condition for the snapper-grouper fishery, SAFMC concluded that dredging near or on hard bottom is potentially the most damaging physical human activity to this habitat (SAFMC 1998b). Dredging can be associated with creation or modification to navigational channels, or removal of sediment for beach nourishment projects. Dredging impacts to hard bottom habitat include the following (SAFMC 1998b):

- Dislocation of corals or colonized rock (live rock) and cuts through live tissue that leads to infection or mortality;
- Sedimentation that stresses corals and other sessile invertebrates, causing mortality if the deposited sediment can not be displaced, which in turn may also displace reef fishes;
- Elevated turbidity for extended periods may continue to stress hard bottom organisms, potentially decreasing survival over time;
- Movement of fill material from beaches by waves and currents can result in increased turbidity at and sedimentation on nearby hard bottom sites.

At beach nourishment projects in Florida, added sand was transported offshore from the beach by cross-shelf currents, covering hard bottom habitat (Marsh and Turbeville 1981; Lindeman and Snyder 1999). Studies off Wrightsville Beach and Atlantic Beach demonstrated how sediment was transported from the nourished beaches across the shoreface in southeastern and central North Carolina waters (Thieler et al. 1995; Thieler et al. 1998; Reed and Wells 2000). Hard bottom was observed to be buried by nourishment

sands in the Wrightsville Beach area (R. Thieler, USGS, pers. com., 2001). Commercial fishermen in the Wrightsville Beach area, where beach nourishment has been conducted regularly since the 1960s, reported that nearshore hard bottom areas that were once productive fishing areas are now covered in sand (public comment at SAFMC public meeting on MPAs, Wrightsville Beach, 2001; B. Cleary, UNC-W, pers. com., 2001). These areas are no longer fished due to poor yield. In Florida, Lindeman and Snyder (1999) observed dramatic decreases in numerical abundance of fish species and individuals following the burial of hard bottom habitat via sand transported from an augmented beach. The cumulative number of species detected 12 months prior to and 15 months after site burial decreased by nearly one order of magnitude, from 54 to eight species, respectively (Lindeman and Snyder 1999). The average number of individual fish recorded per transect also declined, from 38 (pre-burial) to less than one (post-burial) (Lindeman and Snyder 1999).

Dredging large navigation channels through ocean bottom is limited to the entrance channels leading to North Carolina's state ports in Wilmington on the Cape Fear River and in Morehead City on the Morehead City Channel. The dredged channels in the ocean lead into the Cape Fear and Beaufort inlets, respectively. Hard bottom is located in close proximity to the Wilmington channel. In 2002, the navigation channel was rerouted as part of a project to deepen the river channel and port and create a new offshore dredge material disposal site. The proposed route was altered to avoid dredging through hard bottom (F. Rohde, DMF, pers. com., 2002). Dredging and stabilization of other inlets can also potentially impact hard bottom when these activities occur close to shore, such as at New River, Masonboro, or Shallotte inlets. Turbidity and sedimentation associated with dredging may also have indirect effects on hard bottom in the vicinity of dredge sites.

In North Carolina, the frequency and magnitude of beach nourishment has increased over time.[6] If all requested and proposed projects are eventually authorized and conducted, approximately 155 miles (48% of ocean shoreline) would be affected and potentially degraded, excluding the beaches nourished periodically from channel and inlet dredging. All of the existing projects and the majority of the newly authorized projects are located south of Cape Lookout where hard bottom is most abundant, especially in the nearshore area. *The transport of sand from nourished beaches over time should be monitored. Future research should attempt to determine if the probability or extent of burial are affected by sand volume, type, or grain size, by the time-of-year of project initiation, or by the distance between nourished beach and hard bottom. A DENR Beach Management Plan should be developed and implemented which includes specific guidelines to minimize impacts to hard bottom from nourishment projects.*

Fishing and diving

Commercial fishing

Bottom longlines, dredges, fish traps, and bottom trawls can cause rapid and extensive physical damage to living and non-living components of hard bottom (SAFMC 1998b). In a comparative analysis of benthic fishing activities, the largest relative declines in benthic species richness and total numbers of individuals were associated with intertidal dredging (Collie et al. 2000). Fishing gear dragged across the bottom causes direct damage and mortality by breaking attached benthic organisms, such as sponges, anemones, and corals, or outcrop structures from the seafloor. Damage is especially extensive where the bottom is uneven and there is a concentration of coral and other invertebrates. The removal of structure and attached benthic organisms decreases species diversity and reduces structural complexity of hard bottom (Watling and Norse 1998). Dragged gear also indirectly damages bottom habitat by increasing the vulnerability of injured organisms to subsequent diseases and predation, smothering invertebrates with sediment (Auster and Langton 1999), and partially or completely destroying burrows and tubes constructed by invertebrates (Watling and Norse 1998). Trawling also results in an immediate reduction of mobile benthic invertebrates (e.g., polychaetes and crabs) on and adjacent to hard bottom, reducing

[6] Refer to the soft bottom threats section for status, trends, and location of beach nourishment activity, Map 6.2.

food resources available to other reef organisms.[7]

Roller-rigged trawls are a specific type of trawl with large rubber discs that is designed to roll over hard bottom habitat without becoming entangled. A study in South Carolina on the effects of roller-rigged trawls found that 32% of the sponges, 30% of the hard corals, and 4% of the soft corals at a hard bottom site were damaged by a single tow (Van Dolah et al. 1987). Damaged individuals require years to completely regenerate to their initial, pre-disturbance sizes, due to the organisms' slow growth rates (Van Dolah et al. 1987). Another study evaluated impacts from a roller-framed shrimp trawl and found that 50% of the sponges, 80% of the hard corals, and 40% of the soft corals were damaged (Tilmant 1979). In addition, catch rates of all animal groups declined over a five-year period; fewer animals may have been available to be caught due to past trawling effort.

Of the fishing gears that can potentially damage hard bottom, longlines, dredges, and fish traps are of minimal concern because they are used little or not at all in North Carolina state waters. There is currently no active dredge fishery in North Carolina's intertidal or subtidal ocean waters. Use of bottom longlines was prohibited by federal regulations in depths of less than 50 fathoms (300 ft) throughout the South Atlantic area as part of Amendment 4 of the Snapper Grouper Fishery Management Plan in 1991 to reduce fishing mortality and habitat damage. Fish traps can cause significant damage if placed on or dragged through hard bottom. However, federal regulations (Amendment 4, Snapper-Grouper Fishery Management Plan) prohibited the use of large fish traps in 1991. Smaller sea bass pots are allowed if equipped with escape vents and biodegradable panels to release undersize fish and eliminate waste from lost pots ("ghost fishing"). Only a relatively small number of black sea bass pots is placed in state territorial waters. Between 1994 and 2000, the total number of fish pot trips in state territorial waters ranged from 40 to 94 (DMF, unpub. data). Fish pots are more commonly used in federal waters and may have a greater impact to hard bottom in those areas.

Bottom trawling is conducted in North Carolina state ocean waters extensively for shrimp and to a lesser extent for flounder. Shrimp trawl effort in the ocean is most concentrated in the southern district of North Carolina (Onslow, Pender, New Hanover, and Brunswick counties), where hard bottom is most abundant (Figure 7.2). Flounder trawling in the ocean occurs in the northern (Currituck, Dare, Hyde counties) and central (Carteret County) districts, primarily north of Cape Hatteras. The number of flounder trawl trips during 1994–2000 has ranged from 49 to 204 trips/year, while the number of shrimp trawl trips has ranged from 2,500 to 3,500 trips/year (DMF, unpub. data). The extent that trawls contact and damage hard bottom in North Carolina is not known. Because the irregular hard surfaces of hard bottom can tear nets and damage expensive gear, fishermen generally try to avoid those areas. Roller-rigged trawls have been prohibited by federal regulations for targeting snapper-grouper since 1989. In addition, ocean trawling is prohibited within one-half mile of the ocean shoreline from Oregon Inlet north to the Virginia border (MFC rule 15A NCAC 3J.0202). Trawling is also restricted in many other areas, as provided by MFC rules (MFC 2001). *While there is potential for damage, research is needed to determine if and to what extent hard bottom is being damaged by trawling activity in North Carolina, particularly shrimp trawls in the southern portion of the coast. The specific locations of trawl trips should be mapped. To assess potential effects of trawling, experimental trawls of predetermined duration, magnitude and frequency should be conducted in a previously untrawled hard bottom location. The MFC should consider designating nearshore ocean hard bottoms as Strategic Habitat Areas due to their importance as secondary nursery habitat and corridors for gag, black sea bass, and other fisheries resources.*

[7] Refer to Appendix L for a list of the fishing gears used in North Carolina waters and their probable habitat impacts.

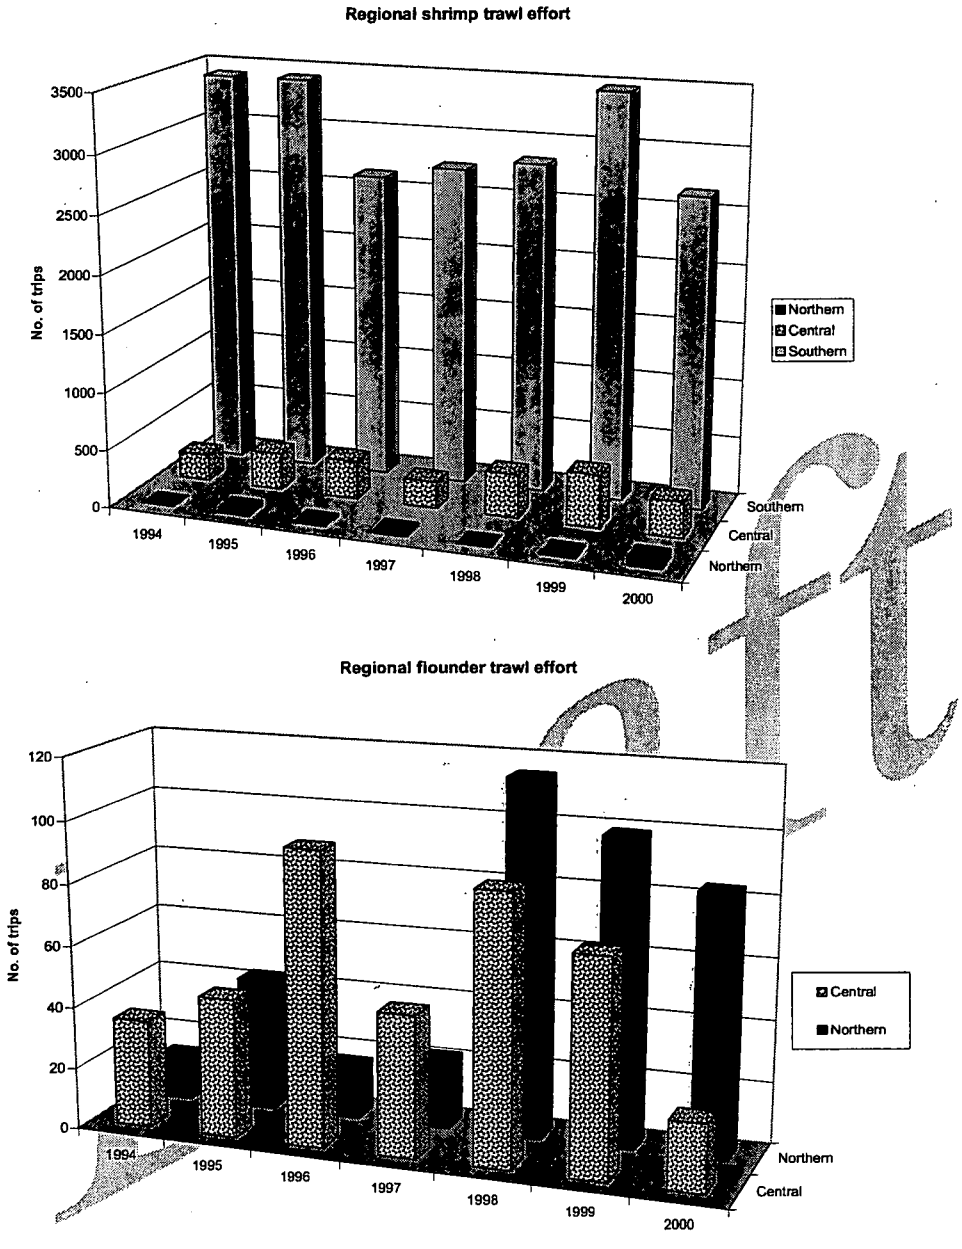

Figure 7.2. Shrimp and flounder trawl fishing effort (number of trips) in North Carolina's nearshore ocean waters (0-3 miles from shore), 1994–2000, by coastal region. *[Source: DMF, unpub. data]*

Recreational fishing

Direct impacts of hook and line gear on hard bottom habitat are considered low. Recreational fishing was identified at a NMFS conference as a major concern because of the large number of participants in the fishery (Hamilton 2000). There were more than six million sport fishing trips in coastal North Carolina in 2001, including more than 500,000 by private boats and charter boats in the ocean. Federal headboat survey data indicate that, additionally, there were more than 1,000 headboat fishing trips in North Carolina's ocean waters south of Cape Hatteras during 2001, involving about 32,000 angler-days (R.

Dixon, NMFS, pers. com., 2002). Hard bottom and artificial reef species are targeted by many recreational fishermen, and may receive concentrated use, leading to unknown cumulative impacts. Anchors and chains from recreational or commercial boats can break corals and other organisms and create lesions, leading to infection (SAFMC 1998b). In addition to habitat damage caused by anchors and chains, lost fishing gear (i.e., line, wire leaders, hooks, sinkers) and discarded rubbish (especially plastics) can entangle or be ingested by marine life, including bottom dwelling organisms. Roughly 52% of marine debris identified in U.S. waters originated from recreational vessels (UNESCO 1994). Chemical contamination from lost lead sinkers is also a concern. *Monitoring of hard bottom is needed to assess the level of impact from hook and line fishing. Educating anglers on the impacts of anchor damage, lost fishing gear and discarded litter to hard bottom habitat and associated species would be helpful in reducing those impacts.* Finally, overfishing of large reef fish predators can indirectly damage hard bottom habitat by creating an imbalance of trophic structure, reducing the quality and productivity of the habitat (NMFS 1999). *This issue is best addressed through fishery management plans, rather than the CHPP process.*

Recreational diving

Diving activities can also damage hard bottom. Divers can kick or overturn corals and live rock, which results in habitat damage. Harvest of live rock for the aquarium trade was found to cause extensive destruction and loss of hard bottom, with additional damage when chemicals were used (SAFMC 1998b). The MFC prohibits harvest or possession of coral or live rock (MFC rule 15A NCAC 3I .0116). The Carteret County area has been rated as one of the premier offshore diving areas in the United States, especially for wreck diving. Recreational spearfishing with power heads has damaged corals where diving activity was concentrated. In North Carolina, however, damage from diving activity is probably minimal due to the relatively low numbers of divers in the inshore areas.

Infrastructure

A relatively new threat to hard bottom comes from the installation or maintenance of fiber optic cables and pipelines placed across oceans and waterways. Cables are increasingly used to transmit telecommunications over long distances and pipelines are used to transport gas products. Since 1988 when the first fiber optic cable was laid across the Atlantic Ocean, an estimated 230,000 miles of oceanic cable have been installed (ASMFC 2001). Fiber optic cables are generally laid directly on the seafloor, and routed into a dredged or bored trench, conduit, or access hole where the cable comes onshore (landing site). Once the access hole or conduit is in place and buried, maintenance or placement of new cables involve dredging these holes back open. While cables are currently being placed under estuarine and inland waters as part of a combined natural gas pipeline and cable project, there are no fiber optic cables located in the ocean off North Carolina at this time (December 2002).

Environmental concerns to hard bottom associated with laying cables or pipelines identified by ASFMC (2001) and Blue Atlantic Transmission System (2003) include:

- During installation, cable "sweeping" and crushing of hard bottom communities can occur, even when pre-construction evaluations and analyses of alternative proposed routes are conducted.
- During repairs, grappling to recover and repair damaged cable has the potential to cause additional impacts to hard bottom resources. The repaired cable is generally not returned to its original location, potentially impacting additional bottom areas.
- When directional drilling (drilling a tunnel under the seafloor) for the landing sites encounters certain subsurface conditions, the pressurized fluid mud used to lubricate the drill hole can escape into the water column. The escaped fluids may cause turbidity plumes and subsequent burial or smothering of sensitive hard bottom resources, and release potentially toxic compounds.
- Sedimentation or excessive suspended sediment can cover hard bottom or impact filter feeders.
- Pipes or cables may restrict or alter invertebrate movement on the seafloor due to physical barrier of

the pipe, noise, vibrations, magnetic fields or other biochemical influences.

These cables and pipes may also pose a conflict for recreational and commercial fishing activities, as well as beach nourishment borrow areas. Permit authority for fiber optic cable corridors in the ocean is vested in the Corps of Engineers, with state review under the DCM consistency process. The ASMFC recommended that offshore corridors be pre-identified and evaluated for environmental impacts and conflicts. The ASMFC also recommended that monitoring be conducted to assess damage and recovery of habitat (ASMFC 2001). *North Carolina should coordinate with ASMFC, other states, and the communications companies to manage the placement of fiber optic cables in North Carolina offshore waters in a manner that minimizes impact to hard bottom and minimizes conflicts with existing activities.*

Water quality degradation

The quality of water at nearshore hard bottom sites is important since fisheries species are most sensitive to toxics and other pollutants during the first months of life. The effect of polluted waters on a given species depends on its life history and feeding behavior. According to the SAFMC (1998b), the primary threats to offshore water quality at hard bottom sites are oil and gas development, offshore dumping, and discharge of contaminants from river and estuarine systems.

The last active offshore oil and natural gas leases in state or federal waters off N.C. were relinquished in November 2000 (<http://www.gomr.mms.gov/homepg/offshore/atlocs/atocsfax.html>, 2003). Several companies, including Amerada Hess, Chevron, Conoco, Marathon, Mobil, Occidental Petroleum Corporation (OXY), and Shell have held interests, singly or jointly, in the Manteo Exploration Unit, a submerged area comprised of 21 lease blocks located approximately 44.8 statute miles northeast of Cape Hatteras (Vigil 1998). Currently, a federal moratorium on oil exploration and development of the eastern U.S. seaboard is in effect until 2012 (<http://dcm2.enr.state.nc.us/Facts/offshore.htm>, 2003). *However, it would be beneficial for the state to develop and implement a policy to prohibit oil and gas drilling in North Carolina's coastal waters, to ensure protection of hard bottom and water column habitats.*

Offshore dumping of dredged material occurs at designated sites in federal waters seaward of the Morehead City and Wilmington ports. A new, enlarged "Ocean Dredge Material Disposal Site" (ODMDS) is being developed by COE off the mouth of Cape Fear River in close proximity to natural hard bottom. The ship channel re-alignment goes through an artificial reef established a few years ago by COE. *Adequate monitoring should be conducted prior to creation and during use of this ODMDS to determine its effect on hard bottom habitat.*

Studies in the Mediterranean Sea examining the effect of pollution on hard bottom benthic communities found that total species richness, abundance, and diversity declined with increasing influence of multiple sources of pollution (Hong 1983) and echinoderm richness and density decreased with proximity to industrial sewage outfalls (Hermelin et al. 1981). Current state (EMC) policies prevent wastewater discharge into the Atlantic Ocean. The only exception to this restriction is the discharge off Oak Island of heated flow-through, non-contact cooling water from a nuclear power plant. *Because nearshore hard bottoms are so vulnerable to damage from physical and water quality changes, this policy should be maintained.*

Hard bottom can be degraded not only by point discharges but by outflowing estuarine and river waters. The effect of estuarine waters on hard bottom in North Carolina's ocean waters is largely unknown since little monitoring has been conducted. In 1999, UNC-W began a Coastal Ocean Monitoring Program (COMP) to assess physical, chemical, and biological properties of the Cape Fear river water plume, extending into Long Bay, and waters in Onslow Bay. Results following Hurricane Floyd found that approximately 200 mi^2 of coastal ocean waters were affected for approximately one month, in terms of turbidity and nutrient levels (<http://rover.phy.uncwil.edu/onslow/CFRPlume/>, 2004). In comparing water quality in nearshore ocean waters in Long Bay, where there is a large riverine influence, to Onslow

Bay, where there is minimal riverine influence, the Long Bay stations had four to seven times greater chlorophyll and nitrate concentrations than stations in Onslow Bay (<http://www.uncw.edu/cmsr/cormp/results.htm>, 2003). Hard bottom is concentrated in Long Bay and the south end of Onslow Bay, where riverine influence has been noted (Map 7.1c). Declines in estuarine water quality are therefore most likely to impact hard bottom in that area. *Monitoring of hard bottom should be initiated and coordinated with UNC-W or other ocean water quality monitoring programs to determine the effects of estuarine water quality, particularly nutrient and sediment loading, on hard bottom.*

Hard bottom in close proximity to shore is more vulnerable to coastal pollution from point and non-point discharge of sewage, industrial waste, and stormwater runoff than offshore hard bottom. Stormwater runoff and discharge of nutrient-rich estuarine waters can increase nutrient levels in coastal ocean waters. Problem levels of nutrients have generally not been found in North Carolina's coastal ocean waters. However, water quality sampling in the ocean waters is extremely limited.[8] Residues of the organochlorine pesticides DDT, PCB, dieldrin, and endrin have been found in gag, red grouper, black grouper, and red snapper, indicating that toxins from stormwater runoff are a potential threat to the hard bottom community (SAFMC 1998b). *Additional water and tissue sampling at hard bottom sites are needed to determine if the benthos of the hard bottom community or the surrounding waters exhibit levels that exceed designated levels of concern.*

Existing management measures

Man-made structures functioning as hard bottom have been given varying levels of designation and protection. In 1975, the wreck of the USS Monitor, a Civil War ironclad located off Cape Hatteras in federal waters, was designated as the first national marine sanctuary. Within North Carolina state territorial waters, the USS Huron, a popular wreck located just 250 yards off the beach in Dare County, was designated by the state as a historic shipwreck preserve (Map 7.1). Despite some concern regarding the effectiveness of artificial reefs, all artificial reefs, along with all natural hard bottom, have been designated by the NMFS as Essential Fish Habitat (EFH). All SAFMC-designated Artificial Reef Special Management Zones (SMZs) are also Habitat Areas of Particular Concern (HAPC) under authority of the federal Sustainable Fisheries Act of 1996 (SAFMC 1998b). Artificial reef SMZs are designated areas surrounding artificial reef sites where certain fishing restrictions or regulations may apply (DMF 1988). The purpose of the designation is to prevent extremely efficient fishing gear from being used on the sites, so that user conflicts are reduced, the resource is used in an orderly manner, biological production is optimized, fish stocks are maintained, and recreational fishing is protected (DMF 1988). There are 21 SMZs in the South Atlantic: seven off Georgia, 11 off South Carolina, one shared by Georgia and South Carolina, and two off Florida. There are no SMZs in North Carolina waters. Fishery management plans adopted by the South Atlantic Council include HAPC designations, which are then put into effect through federal regulations implemented and enforced by NMFS.

Natural hard bottom is protected through several state and federal designations. Certain hard bottom areas were designated as federal Habitat Areas of Particular Concern based on four criteria: 1) importance of ecological functions; 2) sensitivity to human degradation; 3) probability and extent of effects from development; and 4) rarity of the habitat. In North Carolina, all of the nearshore hard bottom areas, two specific offshore areas in Onslow Bay (Ten Fathom Ledge and Big Rock), and the entire shelf break have been given this designation for snapper-grouper (SAFMC 1998a). Approximately 150 reef-associated species have been documented from Ten Fathom Ledge and Big Rock (SAFMC 1998a). Inshore hard bottom (<18 m water depth) is thought to support similar fish species as those documented at Ten Fathom Ledge (P. Parker, NMFS, pers. com., 2001).

The North Carolina Natural Heritage Program inventories, catalogues, and facilitates protection of the

[8] Refer to the Water Column section 2.0 for more information on water quality.

rarest and most outstanding elements of natural diversity in the state. The program designates rare or significant plants, animals, or natural communities, which consequently merit protection or special consideration when making land use and conservation decisions. Currently, four hard bottom ledges within state territorial waters (Map 2.4) have been designated by this state program as Significant Natural Heritage Areas (SNHA) (Natural Heritage Program, unpub. data). These areas include rock outcrops off Bogue Banks (two acres), New River Inlet (1300 acres), South Topsail Island (38 acres), and Masonboro Island (50 acres). There is also one designated intertidal rock outcrop community—the Fort Fisher Coquina Rock outcrops (47 acres). These and other nearshore hard bottom areas are particularly vulnerable to impacts from on-shore land development activities. *These areas should be designated as Strategic Habitat Areas and considered for additional protection under the recent federal Executive Order 13158, which calls for strengthening and expansion of Marine Protected Areas in the United States or through additional state actions specifically designed to protect those sites.*

Several state and federal regulations provide protection for hard bottom habitat. Since 1995, DMF has prohibited directed harvest of all coral or any live rock in North Carolina state waters (MFC rule 15A NCAC 3I .0116). In addition, any live rock or coral which is harvested incidentally with any gear must be returned immediately to the waters where taken. Similar NMFS regulations exist for federal waters. There are a few areas where hard bottom is present and trawling is restricted. This includes the military prohibited and restricted areas and sea turtle sanctuary that are both located in the ocean seaward of Onslow Beach (15A NCAC 3I .0110, 15A NCAC 3I .0107).

Despite the live rock prohibition, hard bottom structure can still be damaged or killed accidentally by certain commercial and recreational fishing gear and boating equipment. Although there is potential for damage, there has been no documentation that fishing gear currently used in North Carolina is damaging hard bottom. An absence of data on past conditions and current fishing and boating effects prevents accurate identification of potential damage to nearshore hard bottom. *Monitoring of hard bottom condition in nearshore waters, as well as fish utilization of the habitat, is the first step in evaluating impacts of fishing gear or threats to that habitat.*

A series of federal regulatory actions have been taken by NMFS to protect hard bottom habitat (SAFMC 1998b). Management measures from the snapper-grouper FMP and subsequent amendments focused on prevention of overfishing through harvest and gear limitations:

- Amendment 1 (1989) addressed habitat damage through prohibition of trawling gear (roller-rigged trawls) for the harvest of species in the snapper-grouper fishery south of Cape Hatteras (SAFMC 1998b);
- Amendment 2 to this plan (1994) prohibited collection of live rock in federal waters. State rules were implemented in 1995 to be consistent with this federal regulation;
- Amendment 4 (1991) prohibited use of fish traps in federal waters, with the exception of black sea bass traps north of Cape Canaveral, Florida. Fish traps cannot be used in North Carolina ocean waters to target snapper-grouper (15A NCAC 3M .0506(s)(1)). These rules limit the potential number of traps and associated impacts to hard bottom in North Carolina. The majority of black sea bass traps is located beyond state waters. Bottom longlines are allowed in south Atlantic federal waters. Collecting corals and use of chemicals are regulated by NMFS pursuant to the 1982 SAFMC Coral Fishery Management Plan (SAFMC 1998b).

Use of Marine Protected Areas has proven effective in habitat protection and fishery enhancement in several areas of the world. A recent study of 89 marine reserves showed that fish and marine life quickly recovered when protected by establishment of marine reserves (Halpern 2003), and the protected areas repopulated adjacent waters (AAAS 2001; Roberts et al. 2001). In New Zealand, overfished snapper populations increased by 40 times within a few years of its establishment, compared to populations outside a reserve. Fish populations tripled in a St. Lucia reserve within three years. North Atlantic sea scallop populations were 14 times greater inside a reserve than outside it after five years of closure.

Estuarine waters near Cape Canaveral that were closed to fishing for over 30 years had 3–12 times greater relative fish abundance than adjacent fished areas (Roberts et al. 2001). In addition, preliminary results from establishment of several no-take reserves in the Florida Keys in 1995 indicate reduced habitat damage and improvement in some reef fish populations, particularly yellowtail snapper and spiny lobster.

Since multiple harvest and gear regulations have not appeared to adequately improve the status of reef fish species in the Snapper-Grouper fishery, and additional species have become overfished, the SAFMC has considered use of Marine Protected Areas as a possible management tool since 1992 (SAFMC 1998b; SAFMC 2001). Marine Protected Areas are considered most effective at protecting species with restricted geographical movements typical of most reef animals or where habitat is limiting (Bohnsack 1993). Creation of MPAs can be a valuable tool for the prevention of or recovery from overfishing. They also protect, and potentially improve, reef habitat previously subjected to physical damage. Finally, MPAs protect age structure, biodiversity, and genetic diversity of fish stocks within their boundaries. Based on the 1992 scoping process, input from SAFMC advisory panels and committees, and an ongoing public involvement process, the SAFMC will likely use some form of MPA's as a fishery management tool in the south Atlantic. There has been little discussion concerning establishment of reserves through state management. The MFC has the authority to establish no-take areas. The Fisheries Director may prohibit or restrict taking of fish and use of any equipment in and around any artificial reef or research sanctuary subject to some conditions (15A NCAC 3I .0109). Many areas within state waters, such as primary nursery areas, are already protected from certain fishing activities through MFC rules. For example, trawling is prohibited in over 46% of North Carolina's estuarine waters. *Hard bottom designated as Strategic Habitat Areas could be considered for incorporation into an MPA to provide protection from fishing gear impacts.*

Two federal Executive Orders issued in 1997 and 2000 also support and encourage establishment of MPAs. In 1997, Executive Order 13089 authorized establishment of a multi-agency task force to direct coral reef conservation in the United States (63 FR 32701–32703, 1998). This task force is exploring recommendations for establishment of MPAs to protect coral reef ecosystems. Establishment of MPAs is currently being considered at Gray's Reef National Marine Sanctuary in Georgia waters (SAFMC 2001). In 2000, Executive Order 13158 directed federal agencies to strengthen the management, protection, and conservation of existing marine protected areas and establish new or expanded MPAs through the creation of a scientifically-based comprehensive national system of MPAs representing diverse marine ecosystems (Federal Register 2000). The MPA executive order calls for:

- Integrated assessments of ecological linkages among MPAs;
- Biological assessment of the minimum area of "No Take" zones needed to preserve representative habitats in different geographic areas of the marine environment;
- An assessment of threats and gaps in levels of protection to natural and cultural resources;
- Practical science-based criteria and protocols for monitoring and evaluating the effectiveness of MPAs;
- Identification of emerging threats and user conflicts affecting MPAs and appropriate, practical, and equitable management solutions, including effective enforcement strategies to eliminate or reduce such threats and conflicts; and
- Assessment of the economic effects of the preferred management solutions.

The DMF should investigate the law enforcement needs necessary to implement MPAs or similar actions for the protection of hard bottom habitat and associated fisheries.

Water quality protection for hard bottom habitat may also result from Executive Order 13158. In addition to establishment of MPAs through NMFS, the order instructs the Environmental Protection Agency (EPA) to identify areas warranting additional protection from pollution and enhancement of water quality standards, and to "propose new science-based regulations, as necessary, to ensure appropriate levels of protection for the marine environment" (Federal Register 2000). The Executive Order also requires the

Department of Commerce and the Department of the Interior to consult with relevant states, and to seek expert advice and recommendations of non-federal scientists and resource managers, and other interested organizations through an advisory committee. More information on MPAs is available on the web (<http://www.mpa.gov>, 2003).

7.5 Summary of Hard Bottom chapter

Hard bottom is valuable to fish because it provides structural complexity for foraging and refuge in marine waters. The presence of ocean hard bottom, along with appropriate water temperatures, allows for the existence of a temperate-to-subtropical reef fish community and a snapper-grouper fishery in North Carolina. Many economically important species and many non-fishery species spawn on nearshore hard bottoms, including black sea bass, Atlantic spadefish, sheepshead, tomtate, white grunt, pinfish, pigfish, damselfish, blennies, sand perch, and inshore lizardfish. Nearshore hard bottoms within North Carolina's ocean waters also serve as important nursery areas for these species as well as provide important secondary nursery habitat for estuarine-dependent fish, such as gag, and black sea bass, as the fish move between estuarine areas and offshore reef areas. All nearshore hard bottoms have been federally designated as Habitat Areas of Particular Concern for the snapper-grouper complex.

Although the current distribution of hard bottom habitat has been mapped, little is known about the biological condition of specific hard bottom sites or how it is changed over time. Wrecks and artificial reefs are beneficial since they add to the total amount of hard structure available to marine organisms and may reduce fishing pressure on natural reefs.

Because of the lack of baseline information on the biological functioning of nearshore hard bottom, the primary management needs for this habitat are continued research and monitoring to determine specific functional importance, determination of status and trends, and protection of existing hard bottom habitats from degradation or destruction. Threats to nearshore hard bottom in North Carolina include beach nourishment, channel dredging, bottom-disturbing fishing gear, and water quality degradation. Channel dredging can directly remove hard bottom habitat or increase turbidity to damaging levels. Sand transported from nourished beaches can cover up hard bottom structure. Bottom-disturbing fishing gear and related equipment, such as bottom trawls and boat anchors, can uproot coral and damage the structure of hard bottom. Excess nutrients, sediments, or toxins can impact growth or survival of the invertebrates living on hard bottom structure. Water-quality degradation to hard bottom originates from nonpoint sources, such as oil and gas from boating activity, oil spills, and nutrient, sediment, or toxin loading from estuarine and riverine discharges. The quality of estuarine waters discharging into marine waters may have the largest overall effect on hard bottom, and can be addressed through the management needs discussed in the other estuarine habitat sections.

CHAPTER 8. STRATEGIC HABITAT AREAS

While recognizing that all fish habitat is important, scientific data show that certain areas contribute disproportionately more to the viability of fishery and forage stocks, and populations of protected species. These areas of high importance should be the primary focus of habitat protection efforts. While the locations of many Strategic Habitat Areas (SHAs) in North Carolina are currently unverified, some are known (i.e., Primary Nursery Areas). Basic criteria for their location are presented in this chapter. This chapter also provides guidance for the identification, delineation, and designation processes. Location and delineation of these areas will be addressed in the eleven Management Unit plans following adoption of this Coastal Habitat Protection Plan.

8.1. DEFINITION

In 1998, the CRC, EMC, and MFC approved the following definition for Strategic Habitat Areas (SHAs):

"Specific locations of individual fish habitats or systems of fish habitats that have been identified to provide exceptional habitat functions or that are particularly at risk due to imminent threats, vulnerability, or rarity. These may include areas previously delineated by other state or federal agencies (AECs, HAPCs, ORWs, for example), or others as deemed necessary in an approved CHPP. Strategic Habitat Areas allow for site-specific management measures to be recommended."

As noted in the SHA definition, management measures will be site-specific based on the fish population dependence on the habitat and the threats to habitat function. Some measures may be broader reaching than others due to the extent of SHAs in a particular Management Unit. As SHAs are identified, each commission and agency involved with activities impacting those areas will determine appropriate regulatory and non-regulatory actions necessary to protect these sites.

8.2. SYSTEM RELATIONSHIPS

In order to locate and delineate SHAs, the relationships among habitats must be considered. While all fish habitats are of ecological value to fish, numerous studies from a variety of areas show that certain spatial relationships among habitats maximize their ecological value to species in those habitats. For example, the overall abundance and biomass of finfish and other animals in tidal freshwater and estuarine creeks are enhanced by proximity of SAV beds to the marsh edge and depth of adjacent creeks (Rozas and Odum 1987a; Ellis 1995; Irlandi and Crawford 1997). Open-water zooplankton are more vulnerable to predation in close proximity to SAV beds providing refuge for small planktivorous fish than zooplankton occurring well away from such areas (SAFMC 1998). In a Texas estuary, densities of small invertebrates (worms, shellfish, insects) in soft bottom are highest adjacent to emergent salt marsh vegetation in the spring (Rozas and Zimmerman 2000). Species using rocky outcrops in North Carolina marine systems were supported by benthic production from adjacent soft-bottom habitat (Posey and Ambrose 1994). Another example of the synergistic effect of habitat diversity is the co-occurrence of oyster reefs and SAV. In turbid areas with reduced SAV coverage, addition or enhancement of oyster reef habitat facilitates filtration of suspended particles from the water column, enhancing light penetration and improving conditions for SAV. Expansion of SAV habitat can lead to increased production of many fishes and invertebrates dependent on that habitat. These studies show how individual habitats can have a greater value to fish production as part of a system or complex of habitats than as isolated sites.

While delineating complexes of related bottom features is important, it is only part of Strategic Habitat Area delineation. Water circulation patterns play a crucial role in larval settlement and post-larval migration to nursery areas. Maintaining water flow among SHAs is therefore an important aspect of SHA management. The water column surrounding bottom features is also affected by water circulation patterns and land use/land cover characteristics affecting the source of that water. Habitat fragmentation

is a well-recognized problem affecting terrestrial wildlife populations (Saunders et al. 1991). In aquatic systems, Turner et al. (1999) found that SAV patch isolation had a significant influence on benthic community composition, suggesting that habitat fragmentation degrades aquatic systems as well as terrestrial systems. *Therefore, consideration should be given to reducing habitat fragmentation in the process of SHA designation.*

8.3. EXISTING HABITAT DESIGNATION AND PROTECTION PROGRAMS

There are no designated Strategic Habitat Areas in North Carolina at this time. However, several different approaches are used in North Carolina to identify, delineate, and designate ecologically important habitat areas. At the federal level, the Magnuson-Stevens Fishery Conservation and Management Act Reauthorization of 1996 [the Sustainable Fisheries Act (SFA)] requires the National Marine Fisheries Service (NMFS) to amend federal Fishery Management Plans (FMPs) to include provisions for protection of "Essential Fish Habitat" (EFH), defined as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." In North Carolina, salt marshes, oyster reefs, and seagrass beds are designated EFH for red drum and penaeid shrimp, species managed cooperatively by state and federal authorities. Similar to CHPP Strategic Habitat Areas, federal "Habitat Areas of Particular Concern" (HAPCs) are designated for areas of EFH that are particularly important for managed species or species complexes (SAFMC 1998). North Carolina Primary Nursery Areas, first designated by the MFC in 1977, are similar in concept to HAPCs. However, the NMFS has designated very few HAPCs (none in North Carolina), while the MFC/DMF and WRC have designated tens of thousands of acres as nursery areas in North Carolina (see below). The state designations are well accepted by the various state and federal regulatory and permitting agencies, as well as by the public.

While the concept of HAPC is similar to that of CHPP Strategic Habitat Areas, there are some important differences. First, measures protecting HAPC are focused on federally funded activities. The scope of HAPC protection is also specific to individual species or groups of similar species and, therefore, does not take a watershed-based approach. For oceanic species managed by the federal government (i.e., tunas), this approach presents no obstacle, but for anadromous (i.e., American shad) and estuarine-dependent (i.e., southern flounder) species, which are of primary importance in North Carolina, the watershed approach best captures the nature of threats and impacts, as well as opportunities for restoration, enhancement, and preservation. Finally, the federal FMPs and their implementing rules do not apply to fishery species managed primarily under state authorities (i.e., oysters, spot).

The MFC and WRC have designated nursery areas since 1977 and 1990, respectively, based on field sampling. Approximately 162,000 acres of Coastal Fishing Waters are currently designated by the MFC as Primary, Secondary, and Special Secondary Nursery Areas. About 10,000 acres of Inland Fishing Waters in the coastal area are designated as Inland Primary Nursery Areas, as well as the following areas of the four main rivers draining to North Carolina's coast:

- Roanoke River, U.S. 258 bridge to Roanoke Rapids Dam (35.5 stream miles, 57.1 km)
- Tar-Pamlico River, railroad bridge at Washington to Rocky Mount Mill Dam (90.2 stream miles, 145.2 km)
- Neuse River, Pitchkettle Creek to Milburnie Dam (160.6 stream miles, 258.4 km)
- Cape Fear River, Lock and Dam #1 to Buckhorn Dam (126.7 stream miles, 203.9 km).

Strategic Habitat Areas are not the same as MFC-defined "Critical habitat areas" [MFC Rule 15A NCAC 3I .0101(20)]. Strategic Habitat Areas may include critical habitat areas, but all critical habitat areas may not be SHAs. The term "Strategic Habitat Areas" is also used to avoid confusion with the term "Critical Habitat" used in the federal Endangered Species Act. There are currently no specific protections for MFC-designated Critical habitat areas within EMC or CRC rules. There are, however, specific protections for designated nursery areas included in the rules of all three commissions. For example, a MFC rule [15A NCAC 3N .0104] prohibits use of trawls, dredges, long haul and swipe seines, and

mechanical shellfishing gears in Primary Nursery Areas (PNAs). Once an area has been designated as a PNA by the MFC, the area also comes under protection of existing CRC rules [15A NCAC 07H .0208] and EMC rules [EMC rule 15A NCAC 02B .0301(c)] that protect physical and water quality parameters of PNAs as a class.

Four classes of Critical habitat areas were defined by a MFC rule in the early 1990s [MFC Rule 15A NCAC 3I (20) – submerged aquatic vegetation, shellfish producing areas, anadromous fish spawning areas, and anadromous fish nursery areas], but no specific areas have yet been designated under that rule. The DMF is currently delineating anadromous fish spawning areas based on sampling conducted from the early 1970s to the present for presentation to the MFC. Although neither CRC nor EMC rules offer any specific protection for anadromous fish spawning or nursery areas, regulatory protections exist for other critical habitat areas, such as submerged aquatic vegetation and shellfish producing areas. Beds of submerged aquatic vegetation are protected from the direct impacts of dredging and trawling (in some locations, MFC rule 15A NCAC 3J .0104), and open shellfish harvesting areas are protected from new marina pollution and wastewater discharges [CRC rule 15A NCAC 07H.0208(5)(E)]. (More information regarding protection of fish habitat types is provided in Chapters 2.0 – 7.0). The piecemeal protection of individual habitat types fails to provide the holistic approach needed to protect entire systems of interdependent habitat. Designation and protection of Strategic Habitat Areas are meant to remedy this problem.

8.4. LOCATION AND DESIGNATION PROCESS

Strategic Habitat Areas will be delineated and recommended for designation in CHPP Management Unit plans. To protect these areas, the CRC, EMC, and MFC would enact appropriate management measures following the Administrative Procedures Act (G.S. 150B) for rulemaking. Recommendations for designation of SHAs will be developed based on existing DMF procedures for identifying PNAs and similar procedures by the other commissions and agencies. Government agencies or private parties may suggest potential areas. The process for identifying and designating SHAs should include the following tasks:

- ***Gather data and information to locate potential Strategic Habitat Areas*** by completing and maintaining habitat mapping (including seagrass, shell bottom, and other bottom types) using the most appropriate technology, monitoring the status of those habitats, and assessing the effects of land use and human activities on those habitats. Data on specific habitat areas (such as small watersheds, bays, or creek segments), fish populations and other natural resources, and potential threats in or near those specific habitat areas, will be compiled, including assessment of linkages between habitats and fisheries resources. Staff will evaluate indicators of biological or ecosystem health and integrity; distribution, status, and trends of the habitat; and threats to habitat quality and quantity.
- ***Identify Strategic Habitat Areas using ecologically based criteria*** developed from information gathered in step 1. The checklist outlined in section 8.5 should be utilized in identifying SHAs.
- ***Develop a spatial database for each proposed SHA.*** The boundaries of each SHA will be mapped and entered into a DENR Geographic Information System (GIS) database. The spatial database will also include habitat types, fish populations and other natural resources, existing protected areas (state, federal and local agencies' designated areas), and potential threats, as well as supporting research and sampling information.
- ***Present recommended Strategic Habitat Areas for designation by the appropriate commission.*** These recommendations will be part of the report associated with the proposed SHA.

Once an area is designated, existing rules and voluntary initiatives pertinent to that area should be compared to potential threats in order to identify any gaps in protecting its current strategic functions. This evaluation could lead to new rules to protect the area, or modifications of existing management

activities (i.e., enforcement, education, land acquisition).

8.5. STRATEGIC HABITAT AREA CHECKLIST

1. The area provides exceptional habitat function for coastal fisheries resources and/or related forage species. The coastal fisheries and forage species and stocks to be considered include the following:
    a. All coastal fisheries species for which North Carolina, interstate, or federal FMPs have been adopted by the MFC, WRC, Atlantic States Marine Fisheries Commission (ASMFC), South Atlantic Fishery Management Council (SAFMC), or Mid-Atlantic Fishery Management Council (MAFMC),
    b. Other species that support important commercial and recreational fisheries in coastal North Carolina,
    c. Forage species important in the diets of the above species
2. The area is documented by specific data or scientific studies as highly important for spawning, nursery, foraging, corridor, or refuge functions.
3. Qualitative information indicates the area is highly important for spawning, nursery, foraging, corridor, or refuge functions.
4. The area is documented by specific data or literature as highly important based on
    a. High and consistent species abundance
    b. High and consistent species diversity
5. The area has been documented to provide important functions for state or federally listed protected aquatic animal or plant species.
6. The area is particularly vulnerable to human impacts or is rare (i.e., uncommon, limited geographic range).
7. The area is at particular risk due to demonstrable threats, as indicated by local development patterns, land use plans, or other applicable information.
8. The area is within an existing state, federal, or local government aquatic area designated to provide some level of protection against degradation or loss (designating authority in parentheses):
    a. Primary nursery areas (MFC)
    b. Critical habitat area (MFC)
    c. Inland primary nursery areas (WRC)
    d. Crab spawning sanctuaries (MFC)
    e. Outstanding Resource Waters (EMC)
    f. Wetlands of exceptional functional significance (DCM)
    g. Habitat areas of particular concern (NMFS)
    h. Significant natural heritage areas (Natural Heritage Program)
    i. Sea turtle sanctuaries (MFC)
    j. North Carolina coastal reserves (CRC)
    k. National estuarine research reserves (NMFS)
9. Marine protected areas (NMFS)
10. The site is within an area set aside for natural resource management or protection (designating authority in parentheses):
    a. State parks, natural and scenic rivers (North Carolina General Assembly)
    b. National parks and seashores (United States Congress)
    c. National wildlife refuges (United States Congress)
    d. National forests (United States Congress)
    e. State game lands (WRC)

CHAPTER 9. MANAGEMENT RECOMMENDATIONS

9.1 INTRODUCTION

The discussions of the six major habitat types in the preceding chapters demonstrate the importance of coastal fish habitats, threats to those habitats, and the need to take actions to achieve the stated goal of the Coastal Habitat Protection Plan as provided by the North Carolina General Assembly: "long-term enhancement of coastal fisheries associated with each coastal habitat." This chapter provides management recommendations based on scientific studies cited in chapters 2.0 – 7.0, deliberations of the Environmental Management, Coastal Resources, and Marine Fisheries commissions, and citizen input from two series of well-attended public meetings (20 in all) held during the summers of 2003 and 2004.

The public cited coastal development as the issue most needing immediate attention, followed by enforcement of statutes, rules, and permit conditions, and then environmental education and research. Threats associated with development included polluted stormwater runoff, sewage discharges, and wetland filling. Meeting attendees agreed that existing laws and rules might be sufficient for habitat protection, but that they are not adequately enforced largely due to insufficient staffing and resources. Educating the public about the importance of coastal habitats and the threats they face was repeatedly mentioned as being critical for successful habitat protection and enhancement.

9.2 THREATS

The CHPP law specifically requires identification of "existing and potential threats to the habitats" and "actions to protect and restore the habitats." (G. S. 143B-279.8) Threats to coastal fish habitat come from many sources and usually affect more than one habitat. Table 9.1 provides a listing and evaluation of the principle threats to the six types of coastal fish habitats identified previously in this report. Development, agriculture, forestry, transportation, channel dredging, and marinas and docks pose the greatest threats. The water column and shell bottom are the most threatened habitats (shell bottom because there is so little of it, and the water column because there are so many pollution sources). All habitats are subject to multiple threats.

Draft

Table 9.1. . Evaluation of specific threats to coastal fish habitat based on hydrologic, physical, and water quality alterations. Darker shading indicates greater impact[1].

ACTIVITY TYPE	THREAT / ACTIVITY	Coastal Fish Habitats					
		Water column	Shell bottom	SAV	Wetlands	Soft bottom	Hard bottom
AGRICULTURE/ AQUACULTURE RELATED	Animal operations						
	Aquaculture (incl. Discharges, intro spp.)						
	Cropland						
	Forestry						
WATER CONTROL	Dams						
	Water withdrawal						
DEVELOPMENT RELATED	Urban/suburban construction activities						
	Urban stormwater runoff (impervious surface)						
	On-site wastewater disposal						
	Permitted industrial wastewater discharges						
	Permitted domestic wastewater discharges						
	Waste disposal (landfills, ocean dumping)						
	Fiber optic cables/utility pipelines						
	Estuarine shoreline stabilization						
	Ocean shoreline hardening						
	Ocean beach nourishment						
TRANSPORTATION RELATED	Impervious roadways						
	Culverts, bridges, and fill (physical blockages)						
FISHING RELATED	Bottom trawl						
	Clam trawl (clam kicking)						
	Toothless dredge (bay scallop)						
	Toothed dredge (crab and oyster)						
	Long haul seines						
	Pots (crab)						
	Rakes, tongs						
	Rod and reel						
NAVIGATION RELATED	Marinas and docks - construction, assoc. NPS						
	Ports (incl. introduced spp. via ballast water)						
	Boating activity						
	Channel and inlet dredging						
	Dredge material disposal (on submerged land)						
MINING RELATED	Phosphate and other minerals						
	Log salvage						
	Oil and gas exploration/drilling						
OTHER	Sea level rise						
	Storm events						
	Disease						
	Introduced or nuisance species						
	Marine debris/litter						

[1]Impact ranking Black - severe; Dark gray - moderate; Light gray - minor; White - none, unknown or potential

9.3 RECOMMENDATIONS

The CHPP development process identified hundreds of management needs, as shown in chapters 2.0 – 7.0. The members of the three Commissions reviewed the issues, along with suggested management actions to address those needs. The Commissions selected four general goals and a series of recommended actions to reach each goal, as shown below. Potential funding sources to support the recommendations were also suggested. In addition to these specific management recommendations, numerous research needs were noted, as shown in Appendix M. The goals, recommendations, and possible funding sources shown below are not listed in any kind of priority order. (Numbers at the end of each recommendation refer to that action as shown in Table 9.2.)

GOAL 1. IMPROVE EFFECTIVENESS OF EXISTING RULES AND PROGRAMS PROTECTING COASTAL FISH HABITATS

Every year, an average of more than 100 acres of Outstanding Resource Waters (the highest quality waters in North Carolina) are closed permanently to shellfish harvest, and miles of previously unaltered estuarine shoreline are artificially hardened with vertical shoreline stabilization structures. Thousands of acres of farmland and forests are uprooted, developed, and paved annually, and nutrient-contaminated Public Trust waters suffer from low oxygen events and fish kills. Existing rules and Table 9.1.Evaluation of specific threats to coastal fish habitats based on hydrologic, physical, and water quality alterations. Darker shading indicates greater impact[1].
programs have had only limited success in protecting and enhancing coastal fish habitat and fisheries resources. The following non-regulatory actions must be taken for existing management strategies to be effective:

- Enhance enforcement of, and compliance with, Coastal Resources Commission (CRC), Environmental Management Commission (EMC), and Marine Fisheries Commission (MFC) rules and permit conditions (#16).
- Coordinate and enhance water quality, physical habitat, and fisheries resource monitoring (including data management) from headwaters to the nearshore ocean (#18).
- Enhance and expand educational outreach on the value of fish habitat, threats from human activities, effects of non-native species, and reasons for management actions (#15).
- Coordinate rulemaking and enforcement among regulatory commissions and agencies (#17).

GOAL 2. IDENTIFY, DESIGNATE, AND PROTECT STRATEGIC HABITAT AREAS

Growing resident and visitor populations in coastal North Carolina will further stress productive coastal habitats and fisheries resources through expansion of support services and infrastructure. Inland development degrades the water quantity and quality of streams that flow to the coastal sounds, as do increased boating and some fishing activities. Certain areas are especially important to fish production, and others are particularly vulnerable to these threats. Greater protection for these "Strategic Habitat Areas" must be a high priority in order to maintain a healthy coastal ecosystem. The following regulatory and non-regulatory management actions should be implemented:

- Gather information to identify Strategic Habitat Areas by
    a) Coordinating, completing, and maintaining habitat mapping (including seagrass, shell bottom, and other bottom types) using the most appropriate technology (#1).
    b) Monitoring the status of those habitats (#1).
    c) Assessing effects of land use and human activities on those habitats (#1).
- Identify and designate Strategic Habitat Areas using ecologically based criteria (#2).
- Analyze existing rules and enact measures needed to protect Strategic Habitat Areas (#2).
- Improve programs for conservation (including voluntary actions) and acquisition of areas supporting Strategic Habitat Areas (#2).

GOAL 3. ENHANCE HABITAT AND PROTECT IT FROM PHYSICAL IMPACTS

Studies estimate that up to 50% of North Carolina's original wetlands have been destroyed since colonial times. Development continues to cause degradation and permanent loss of coastal and non-coastal wetlands. Significant negative impacts to wetlands may occur through a combination of larger projects that require state and federal permits and numerous small, unrecorded actions. Regardless of magnitude, each impact contributes to the cumulative loss of habitat functions and biological productivity. Shell bottoms (oyster reefs) in coastal North Carolina were decimated by uncontrolled fishing methods more than a century ago, and later by construction of the Atlantic Intracoastal Waterway in the 1930s. Since that time, hurricanes, mechanical harvest methods, small scale dredging and filling projects, and diseases and parasites have continued to reduce remaining shellfish bottoms, particularly subtidal oyster beds in the Pamlico Sound system, and impede establishment of new shell bottoms. Submerged aquatic vegetation (sea grass, SAV) in low salinity areas, such as Albemarle Sound and western Pamlico Sound, has all but disappeared. Submerged aquatic vegetation is highly vulnerable to physical disturbances, as well as to water quality degradation, especially turbidity. Strong management actions are necessary to reverse historic and current habitat losses and restore wetlands, shellfish beds, and SAV. The following regulatory and non-regulatory measures are recommended:

- Greatly expand habitat restoration, including:
  a) Creation of subtidal oyster reef no-take sanctuaries (#7).
  b) Re-establishment of riparian wetlands and stream hydrology (#7).
- Prepare and implement a coast wide beach and inlet management plan that requires ecologically based guidelines for minimization of impacts to fish habitats, while addressing socio-economic concerns (#3).
- Protect Submerged Aquatic Vegetation (SAV), shell bottom, and hard bottom areas from fishing gear impacts through improved enforcement, establishment of protective buffers around habitats, and further restriction of mechanical shellfish harvesting (#5).
- Protect fisheries resource habitat by revising estuarine and public trust shoreline stabilization rules using best available scientific information, considering estuarine erosion rates, and development and promotion of incentives for alternatives to vertical shoreline stabilization measures (#4).
- Protect and enhance habitat for anadromous fishes by:
  a) Incorporating the water quality and quantity needs of fish in surface water use planning and rule making (#6).
  b) Eliminating obstructions to fish movements, such as dams, locks, and road fills (#6).

GOAL 4. ENHANCE AND PROTECT WATER QUALITY

Because all fish habitats are connected through the water column, maintaining and restoring water quality is the basic component of habitat protection and enhancement. Runoff from developed lands (structures, parking lots, roads, residential yards), agricultural fields and facilities, and intensively managed forests carries excess nutrients into surface waters, which can lead to algae blooms that reduce water clarity and lower dissolved oxygen in the water column. Turbidity from runoff can suppress SAV growth, cause low oxygen events leading to fish kills, and cause mortality of organisms in the bottom community, including oysters. Excess sediment clouds the water, reduces SAV growth and survival, fills in creeks and small water bodies with silt, and degrades spawning and nursery habitats. Heavy metals and pesticides transported into the water with storm water can accumulate in the bottom sediments and organisms. Through the food chain, such pollutants may contaminate fish, affecting their survival and growth, and making them unsafe for human consumption. Runoff also carries fecal material to surface waters after rain events, requiring closure of tens of thousands of acres of shellfishing waters to harvest to protect human health.

Spills and other failures of municipal and on-site wastewater treatment facilities and infrastructure often

send sewage pollution downstream, contributing to algae blooms, and causing shellfishing closures and restrictions on swimming in public waters. Some coastal towns dispose of stormwater on the ocean beaches, while others drain it to the ocean or estuaries. These discharges degrade water quality, leading to shellfishing closures and notifications warning of possible public health dangers from contact with contaminated water. These warnings have a detrimental effect on tourism. Marinas also degrade water quality and restrict use of Public Trust waters via mandatory shellfish harvest closures. Large-scale animal farming expanded rapidly in eastern North Carolina in the 1990s and management of hog waste became a major environmental problem. Current methods generally used for hog waste management can greatly increase nutrient loading to adjacent waters through excessive spraying on fields, aerial deposition, and spills. The following regulatory and non-regulatory management measures are necessary to address a diversity of point and non-point pollution sources:

Point sources

- Reduce point source pollution by:
  a) Enhancing inspections of sewage treatment facilities, collection infrastructure, and land disposal sites (#8).
  b) Providing incentives for upgrading all types of wastewater systems (#8).
- Amend rules to prohibit ocean wastewater discharges (#9).
- Prohibit new or expanded stormwater outfalls to coastal beaches and to coastal shellfishing waters (EMC surface water classifications SA and SB) and continue to phase-out existing outfalls by implementing alternative stormwater management strategies (#10).

Non-point sources

- Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through voluntary actions, Best Management Practices (BMPs) and incentives, including:
  a) Improved methods for reducing sediment pollution from construction sites, agriculture, and forestry (#12).
  b) Increased on-site infiltration (#12).
  c) Documentation and monitoring of small but cumulative impacts to wetlands and streams resulting from un-permitted/un-mitigated activities (#12).
  d) Incentives for low impact development (#12).
  e) Enhanced inspections of onsite wastewater treatment facilities (#8).
  f) Increased water re-use and recycling (#12).
- Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through rule making, including:
  a) Larger vegetated buffers (#11);
  b) More stringent impervious surface limits (#11);
  c) Expansion of Areas of Environmental Concern (AECs) upstream and landward (#11);
  d) Establishment of setbacks along estuarine and public trust shorelines (#11);
- Develop and implement a comprehensive coastal marina and dock management plan and policy to prevent closures of shellfish harvest waters and cumulative impacts to fish habitats (#14).
- Reduce non-point source pollution from animal operations by the following actions:
  a) Continue the moratorium on new/expanded swine operations until alternative waste treatment technology is implemented (#13).
  b) Use a greater percentage of agricultural conservation funds to phase-out or re-locate concentrated animal operations in sensitive areas (#13).
  c) Mandate the phase-out of waste lagoons by a specific deadline (#13).
  d) Use improved siting criteria to protect fish habitats (#13).

9.4. POSSIBLE FUNDING SOURCES

Draft

Implementation of the above recommendations will involve new program activities and revised priorities for existing programs within DENR and other agencies. Significant new funding is essential to expand and improve enforcement and compliance monitoring to fully implement existing laws and rules. Coordinating and expanding DENR biological, physical, and chemical monitoring and data management within the eight coastal river basins will provide local and state environmental managers and regulatory commissions, as well as the development, agriculture, and forestry communities, with data and analyses necessary to make informed decisions, and to evaluate the effects of those decisions. Implementation of coordinated interagency management requires a significant infusion of personnel, equipment, and operations monies. These funds must be considered as an investment in greatly enhanced environmental productivity that will benefit all citizens and provide important dividends over the long-term.

- Request expansion funds from the North Carolina General Assembly.
- Dedicate funds collected through sale and renewal of a Coastal Recreational Fishing License to manage coastal fish habitats.
- Dedicate funds collected through sale and renewal of a Coastal Recreational Fishing License to environmental education and outreach.
- Incorporate CHPP recommendations into North Carolina Clean Water Management Trust Fund priorities.
- Establish severance fees for commercial extraction of natural resources from coastal lands and waters and utilize such funds to enhance, protect, restore, and manage coastal fisheries resource habitats.
- Support protection, enhancement, restoration, and management of coastal fish habitats by establishing a Coastal Fish Habitat Protection Fund supported by impact fees on development in the vicinity of coastal fish habitats.
- Work with the DENR Ecosystem Enhancement Program to implement coastal habitat restoration projects.
- Develop partnerships to restore and protect coastal fish habitats through private and federal programs, such as the FishAmerica Foundation, Restore America's Estuaries, NOAA Restoration Center, and the U.S. Fish and Wildlife Service.

Draft

Table 9.2 Recommended actions to protect, enhance, restore, and manage habitats important for North Carolina's coastal fisheries resources.

Reference numbers	Recommended actions to protect, enhance, restore and manage coastal fish habitats	Responsible commission or agency [Lead group(s) in bold]	Require rule making?
1	Evaluate potential Strategic Habitat Areas by a) coordinating, completing, and maintaining habitat mapping (including seagrass, shell bottom, and other bottom types) using the most appropriate technology, b) monitoring the status of those habitats, and c) assessing effects of land use and human activities on those habitats.	**MFC/DMF**, CRC/DCM, DENR	No
2	Identify and designate Strategic Habitat Areas using ecologically based criteria, analyze existing rules and enact measures needed to protect Strategic Habitat Areas, and improve programs for conservation (including voluntary actions) and acquisition of areas supporting Strategic Habitat Areas.	**DENR**, CRC, EMC, MFC, WRC	Yes
3	Prepare and implement a coast wide beach and inlet management plan that requires ecologically based guidelines for minimization of impacts to fish habitat, while addressing socio-economic concerns.	**CRC/DCM**, EMC/DWQ, MFC/DMF, DWR, WRC, DENR	Yes
4	Protect fish habitat by revising estuarine and public trust shoreline stabilization rules using best available information, considering estuarine erosion rates, and the development and promotion of incentives for use of alternatives to vertical shoreline stabilization measures.	**CRC/DCM**	Yes
5	Protect Submerged Aquatic Vegetation (SAV), shell bottom, and hard bottom areas from fishing gear effects through improved enforcement, establishment of protective buffers around habitats, and further restriction of mechanical shellfish harvesting.	**MFC/DMF**	Yes

Reference numbers	Recommended actions to protect, enhance, restore and manage coastal fish habitats	Responsible commission or agency [Lead group(s) in bold]	Require rule making?
6	Protect and enhance habitat for anadromous fishes by a) incorporating the water quality and quantity needs of fish in surface water use planning and rule making, and b) eliminating obstructions to fish movements, such as dams, locks and road fills.	**DENR**, EMC, DWQ, DWR, WRC, DMF,	Yes
7	Greatly expand habitat restoration, including a) creation of subtidal oyster reef no-take sanctuaries and, b) re-establishment of riparian wetlands and stream hydrology.	**DMF**, EEP	No
8	Reduce point source pollution from human sewage by a) increasing inspections of sewage treatment facilities, collection infrastructure, land disposal sites, and onsite wastewater treatment facilities, and b) providing incentives for upgrading all types of wastewater treatment systems.	**EMC**, DWQ, CHS, DEH	No
9	Adopt or modify rules or statutes to prohibit ocean wastewater discharges.	EMC	Yes
10	Prohibit new or expanded stormwater outfalls to coastal beaches and to coastal shellfishing waters (EMC surface water classifications SA and SB), and continue to phase-out existing outfalls by implementing alternative stormwater management strategies.	**EMC**, DWQ, CRC, DCM, CHS, DEH	Yes
11	Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through rule making, including a) larger vegetated buffers, b) more stringent impervious surface limits, c) expansion of Areas of Environmental Concern (AECs) upstream and landward, and d) establishment of setbacks along estuarine and public trust shorelines.	**EMC**, **CRC**, DWQ, DCM, SCC, DLR	Yes

Reference numbers	Recommended actions to protect, enhance, restore and manage coastal fish habitats	Responsible commission or agency [Lead group(s) in bold]	Require rule making?
12	Improve land-based strategies to reduce non-point pollution and minimize cumulative losses to wetlands and streams through voluntary actions, Best Management Practices (BMPs), and incentives, including a) improved methods to reduce sediment pollution from construction sites, agriculture, and forestry, b) increased on-site infiltration of stormwater, c) documentation and monitoring of small but cumulative impacts to wetlands and streams resulting from un-permitted/un-mitigated activities, d) incentives for low-impact development, and e) increased water re-use and recycling.	**DENR**, EMC, CRC, DWQ, DCM, SCC, DLR, S&WCC, DS&WC, Dept. of Agriculture & Consumer Services, DFR	No
13	Reduce non-point source pollution from concentrated animal operations by the following actions: a) continue the moratorium on new/expanded swine operations until alternative waste treatment technology is implemented, b) use a greater percentage of agricultural conservation funds to phase-out concentrated animal operations in sensitive areas and relocate operations from sensitive areas, c) mandate the phase-out of waste lagoons by a specific deadline, and d) use improved siting criteria to protect fish habitat.	**General Assembly**, **DENR**, EMC, DWQ, S&WCC, DS&WC, Dept. of Agriculture & Consumer Services	Yes
14	Develop and implement a comprehensive coastal marina and dock management plan and policy to prevent closures of shellfish harvest waters and minimize cumulative impacts on fish habitat.	**CRC/DCM**, EMC, DWQ, DMF, WRC	Yes
15	Enhance and expand educational outreach on the value of fish habitat, threats from human activities, effects of non-native species, and the reasons for management measures.	**DENR**	No
16	Expand enforcement of, and compliance with, Coastal Resources Commission (CRC), Environmental Management Commission (EMC), and Marine Fisheries Commission (MFC) rules and permit conditions.	**CRC/DCM**, **EMC/DWQ**, **MFC/DMF**, CHS, SCC, WRC, DFR, DLR, S&WCC	No

Reference numbers	Recommended actions to protect, enhance, restore and manage coastal fish habitats	Responsible commission or agency [Lead group(s) in bold]	Require rule making?
17	Coordinate rulemaking and enforcement among regulatory commissions and agencies.	**EMC, CRC, MFC, DENR, WRC**	No
18	Coordinate and enhance water quality, physical habitat, and fisheries resource monitoring (including data management) from headwaters to the nearshore ocean.	**DENR**, DMF, DWQ, DCM, WRC	No

Appendix A:
State, federal, and interstate programs affecting Coastal Fish Habitat in North Carolina

Public Trust Doctrine- Implemented as part of North Carolina's constitution; applied in management of North Carolina's coastal lands, surface waters, and the resources in those waters. The doctrine states that "public trust lands, waters, and living resources in a State are held by the State in trust for the benefit of all the people, and establishes the right of the public to fully enjoy public trust lands, waters, and living resources for a wide variety of recognized public uses. The doctrine also sets limitations on the States, the public, and private owners, as well as establishing the responsibilities of the States when managing these public trust assets" (Coastal States Organization, Inc. 1997:1).

North Carolina General Assembly - Enacts statutes affecting all of North Carolina. State laws and rules implementing those laws cannot over rule federal laws. However, state actions can be more restrictive than federal rules for environmental protection.

North Carolina Fisheries Reform Act of 1997 (FRA) - Includes a provision [G.S. 143B-279.8] for preparation of a Coastal Habitat Protection Plans (CHPPs) by the N.C. Department of Environment and Natural Resources, with adoption and implementation by three regulatory commissions and their administrative agencies.

Magnuson-Stevens Fisheries Conservation and Management Act of 1976 - The basic law giving the federal government fisheries management authority in the ocean. The reauthorization law (in 1996) is known as the Sustainable Fisheries Act (SFA), which established the basis for federal designation of "Essential Fish Habitat" (EFH).

National Marine Fisheries Service (NMFS) - The agency in the National Oceanic and Atmospheric Administration (NOAA) charged with principal responsibilities for management of the Nation's fisheries and fish habitat in the oceans beyond individual states' jurisdictions. Federal fishery management plans must include provisions for the protection of Essential Fish Habitat (EFH) from negative impacts from federally funded activities.

Coastal Resources Commission (CRC) - One of three North Carolina regulatory commissions that must adopt CHPPs and implement their recommendations. The CRC enacts rules to manage development and land disturbing activities along estuarine and ocean shorelines, shoreline stabilization, alteration of submerged bottoms and coastal wetlands and marina construction. The Division of Coastal Management (DCM), an agency of the N.C. Department of Environment and Natural Resources, implements CRC rules.

Environmental Management Commission (EMC) - One of North Carolina regulatory commissions that must adopt CHPPs and implement their recommendations. The EMC has wide-ranging authority over activities affecting water quality statewide. Rules adopted by the EMC govern point and nonpoint discharges, wastewater management, alteration of non-coastal wetlands, and stormwater management. Several different DENR agencies implement EMC rules, including the divisions of Water Quality (DWQ), Air Quality (DAQ), Water Resources (DWR), and Land Resources (DLR) of the N.C. Department of Environment and Natural Resources.

Marine Fisheries Commission (MFC) - One of three North Carolina regulatory commissions that must adopt CHPPs and implement their recommendations. The MFC manages commercial and recreational fishing practices in coastal waters through rules implemented by the Division of Marine Fisheries (DMF), and agency of the N.C. Department of Environment and Natural Resources.

Intercommission Review Committee (IRC) - A committee of two members from each of the three regulatory commissions (EMC, CRC, MFC), who reviewed the CHPP and developed the management recommendations.

Division of Marine Fisheries (DMF) - DENR agency that implements MFC rules affecting commercial and recreational fishing practices in coastal waters, including rules governing effects of fishing practices on fish habitats. The DMF also conducts extensive monitoring and research programs concerning fish stocks, landings statistics, licensing, and enforcement, and prepares and implements state fishery management plans.

Division of Water Quality (DWQ) - One of the DENR agencies that implements rules of the Environmental Management Commission to govern point and nonpoint discharges into surface waters, wastewater management, alteration of non-coastal wetlands, and stormwater management. The DWQ conducts an extensive statewide water quality-monitoring program, manages permit programs for wetlands impacts and wastewater discharges, and prepares and implements basinwide management plans.

Division of Air Quality (DAQ) - One of the DENR agencies that implements rules of Environmental Management Commission to govern discharges of particulates and gases into the atmosphere. The DAQ operates a statewide network to monitor air quality.

Division of Water Resources (DWR) - One of the DENR agencies that implements rules of Environmental Management Commission pertaining to use of water resources and water supply. The DWR manages state grant programs for water resource development projects, such as navigation and ocean beach nourishment.

Division of Land Resources (DLR) - The DLR administers rules adopted by Sedimentation Control Commission to control sediment transport from land development, as well as rules of the N.C. Mining Commission. The DLR administers the State's dam safety program, and also includes the N.C. Geological Survey and the N.C. Geodetic Survey.

Division of Coastal Management (DCM) - DENR agency that implements rules adopted by the CRC to manage development and land disturbing activities along estuarine and ocean shorelines, shoreline stabilization, alteration of submerged bottoms and coastal wetlands and marina construction through permit programs. The DCM also sponsors and conducts research and analysis concerning coastal erosion and wetlands mapping.

The North Carolina Wildlife Resources Commission (WRC) - The state agency charged with management of inland fisheries, hunting, and management of wildlife, birds, and protected species. The WRC has over most anadromous fish spawning areas in coastal rivers and creeks. The WRC conducts fisheries research on a statewide basis.

Appendix C: Land cover descriptions (from DWQ Basinwide Planning documents)

Natural Resources Inventory land cover type	Land cover descriptions
Cultivated cropland	Harvestable crops including row crops, small-grain and hay crops, nursery and orchard crops, and other specialty crops.
Uncultivated crop	Summer fallow or other cropland not planted.
Pastureland	Includes land that has a vegetative cover of grasses, legumes and/or forbs, regardless of whether or not it is being grazed by livestock.
Forest land	Land at least 10% stocked by single-stemmed trees of any size which will be at least 4 meters at maturity, and land bearing evidence of natural regeneration of tree cover. The minimum area for classification of forestland is 1 acre, and the area must be at least 1,000 feet wide.
Urban and built-up	Includes airports, playgrounds with permanent structures, cemetaries, public administration sites, commercial sites, railroad yards, construction sites, residences, golf courses, sanitary landfills, industrial sites, sewage treatment plants, institutional sites, water control structure spillways and parking lots. Including highways, railroads and other transportation facilities if surrounded by other urban and built-up areas. Tracts of less than 10 acres that are completely surrounded by urban and built-up lands.
Other	Rural transportation: Consists of all highways, roads, railroads and associated right-of-ways outside urban and built-up areas; private roads to farmsteads; logging roads; and other private roads (but not field lanes).
	Small water areas: Waterbodies less than 40 acres; streams less than 0.5 miles wide.
	Minor land: Lands that do not fall into one of the other categories.

Appendix D: Land Cover by Management Unit shown as acreage and percentage of total by river basin. [Sources: Natural Resource Conservation Service (NRCS) and National Resource Inventory (NRI) reports. See Maps 1.2 and 2.17 for spatial reference.]

USGS hydrologic unit (CHPP MU)	Year	Landcover types						
		Cultivated crop	Uncultivated crop	Pasture	Forest	Urban/built-up	Other land cover[1]	Total

Appendix F: Acronyms (Part 1) and Definitions (Part 2)

Part 1: Acronyms

Acronym	Meaning
A	One of the three primary surface water classifications established by the N.C. Environmental Management Commission
AAAS	American Association for the Advancement of Science
ACOE	U.S. Army Corps of Engineers (see "COE" and "USACOE" below)
ADCP	Acoustic Doppler Current Profiling
AEC	Area of Environmental Concern as established by the Coastal Resources Commission under the Coastal Area Management Act (CAMA)
AFS	American Fisheries Society
AIWW	Atlantic Intracoastal Waterway (see "ICW" below)
APES	Albemarle-Pamlico Estuarine System
ASMFC	Atlantic States Marine Fisheries Commission
B	One of the three primary surface water classifications established by the N.C. Environmental Management Commission
BACIPS	Before-After-Control-Impact Paired Series
BEACH	Beaches Environmental Assessment and Coastal Health Act of 2000
BMPs	Best Management Practices
BOD	Biological Oxygen Demand
BRACO	North Carolina Blue Ribbon Advisory Council on Oysters
C	One of the three primary surface water classifications established by the N.C. Environmental Management Commission
CAAE	Center for Applied Aquatic Ecology at North Carolina State University
CAMA	North Carolina Coastal Area Management Act
CBF	Chesapeake Bay Foundation, Inc.
CCA	Copper, chromium, and arsenic used together as a wood preservative
C-CAP	Coastal Change Analysis Program
CCPCA	Central Coastal Plain Capacity Use Area
cfs	Cubic feet per second
CFZ	Coastal frontal zone
CGIA	Center for Geographic Information and Analysis in DENR
CHAs	Critical Habitat Areas as defined by the MFC
CHPP	Coastal Habitat Protection Plan
CHS	North Carolina Commission for Health Services
C-MAN	Coastal-Marine Automated Network
CMSR	Center for Marine Science Research at the University of North Carolina - Wilmington
COBRA	Coastal Barrier Resources Act
COE	U.S. Army Corps of Engineers (see "ACOE" above and "USACOE" below)
CORMP	Coastal Ocean Research and Monitoring Program
CPUE	Catch per unit effort
CRC	North Carolina Coastal Resources Commission
CREP	Conservation Reserve Enhancement Program of the U.S. Department of Agriculture
CREWS	Coastal Region Evaluation of Wetland Significance, a program of the DCM
CWMTF	North Carolina Clean Water Management Trust Fund
DCM	North Carolina Division of Coastal Management in DENR
DDD	1,1-dichloro-2,2-bis(p-chlorophenyl)ethane
DDE	1,1-dichloro-2,2-bis(p-chlorophenyl)ethylene
DDT	Dichlorodiphenyltrichloroethane
DEH	North Carolina Division of Environmental Health in DENR
DEHNR	North Carolina Department of Environment, Health and Natural Resources
DENR	North Carolina Department of Environment and Natural Resources
Dermo	*Perkinus marinus*, an oyster parasite
DFR	North Carolina Division of Forest Resources in DENR
DLR	North Carolina Division of Land Resources in DENR
DMF	North Carolina Division of Marine Fisheries in DENR
DNA	Deoxyribonucleic acid
DO	Dissolved oxygen
DOT	North Carolina Department of Transportation
DSWC	North Carolina Division of Soil and Water Conservation in DENR
DWQ	North Carolina Division of Water Quality in DENR
EA	North Carolina Division of Soil and Water Conservation
ECU	East Carolina University
EEP	Nort Carolina Ecosystem Enhancement Program in DENR
EEZ	Exclusive Economic Zone
EFH	Essential Fish Habitat
EIS	Environmental Impact Statement
EMAP	Environmental Monitoring and Assessment Program
EMC	North Carolina Environmental Management Commission
EO	Executive Order
EPA	U.S. Environmental Protection Agency (see "USEPA" below)
FC	Fecal coliform bacteria
FLDEP	Florida Department of Environmental Protection
FMP	Fishery Management Plan
FPGs	Forestry Practice Guidelines
FWS	U.S. Fish & Wildlife Service
FWS	Future Water Supply

Acronym	Meaning
FY	Fiscal year
GIS	Geographic Information System
HAPC	Habitat Area(s) of Particular Concern
HB	House Bill
HQW	High Quality Water (EMC supplemental water quality classification)
HU	Hydrologic unit
ICW	Atlantic Intracoastal Waterway (see "AIWW" above)
JAI	Juvenile abundance index
LC50	Lethal concentration 50%
MAFMC	Mid-Atlantic Fishery Management Council
MARMAP	Marine Resources Monitoring, Assessment, and Prediction Program
MFC	North Carolina Marine Fisheries Commission
mgd	Million gallons per day
MHW	Mean high water
MLW	Mean low water
MMS	Minerals Management Service of the U.S. Department of the Interior
MODMON	Neuse River Estuary Modeling and Monitoring project
MPA	Marine Protected Area
MS4s	Municipal separate storm sewer systems
MSX	*Haplosporidium nelsoni*, an oyster parasite
MU	Management Unit
NAWQA	National Water Quality Assessment
NCAC	North Carolina Administrative Code
NCDEHNR	North Carolina Department of Environment, Health and Natural Resources
NCDOT	North Carolina Department of Transportation
NCGS	North Carolina General Statute
NCSU	North Carolina State University
NCWRP	North Carolina Wetlands Restoration Program
NHP	Natural Heritage Program
NM	Nautical mile
NMFS	National Marine Fisheries Service
NOAA	National Oceanic and Atmospheric Association
NPDES	National Pollution Discharge Elimination System
NRC	National Research Council
NRCS	Natural Resources Conservation Service of the U.S. Department of Agriculture
NRI	National Resource Inventory
NSW	Nutrient Sensitive Waters (EMC supplemental water quality classification)
NTA	No Trawl Areas
NTU	nephelometric turbidity unit
NWI	National Wetland Inventory
NWR	National Wildlife Refuge
ODMDS	Ocean Dredge Material Disposal Site of the U.S. Army Corps of Engineers
ORCs	???
ORM	Organic rich mud
ORW	Outstanding Resource Water (EMC supplemental water quality classification)
PAHs	Polycyclic aromatic hydrocarbons
PCBs	Polychlorinated biphenyls
PNA	Primary Nursery Area as designated by the MFC
ppm	Parts per million
ppt	Parts per thousand
RO	Reverse osmosis, a method for purifying water
SA	One of the three primary surface water classifications for coastal waters established by the N.C. Environmental Management Commission
SAFMC	South Atlantic Fishery Management Council
SAV	Submerged aquatic vegetation
SB	One of the three primary surface water classifications for coastal waters established by the N.C. Environmental Management Commission
SB	Senate Bill
SBFMP	Striped Bass Fishery Management Plan
SC	One of the three primary surface water classifications for coastal waters established by the N.C. Environmental Management Commission
SCC	North Carolina Sedimentation Control Commission
SCDHEC	South Carolina Department of Health and Environmental Control
SCMRD	South Carolina Marine Resources Division
SEAMAP	Southeast Area Monitoring and Assessment Program
SEAMAP-SA	Southeast Area Monitoring and Assessment Program - South Atlantic
SECC	Sedimentation and Erosion Control Commission
SMZ	Federal Artificial Reef Special Management Zone
SMZ	Streamside Management Zone
SNA	Secondary Nursery Area as designated by the MFC
SNHA	Significant Natural Heritage Area
SOC	Schedule of Compliance
SSMAs	Shellfish/Seed Management Areas of the DMF
SSR	Stock Status Report of the DMF

Acronym	Meaning
STORET	Storage and Retrieval System (a data management system)
SW	Swamp waters (EMC supplemental water quality classification)
TBT	Tributyltin, a major component formerly in antifouling paints, now outlawed
TL	Total length
TR	Trout waters (EMC supplemental water quality classification)
TRC	Total residual chlorine
TSS	Total suspended solids
UM	Ulcerative mycosis, a penetrating skin infection of fishes
UNC	University of North Carolina
UNC-IMS	University of North Carolina - Institute of Marine Science
UNC-W	University of North Carolina - Wilmington
USACOE	United States Army Corps of Engineers (see "ACOE" and "COE" above)
USC	United States Code
USCG	United States Coast Guard
USDA	United States Department of Agriculture
USEPA	United States Environmental Protection Agency (see "EPA" above)
USFWS	United States Fish & Wildlife Service of the U.S. Department of the Interior
USGS	United States Geological Survey of the U.S. Department of the Interior
UV	Ultraviolet light
WRC	North Carolina Wildlife Resources Commission
WRP	Wetland Restoration Program of the Ecosystem Enhancement Program of DENR
WS	Water Supply (EMC supplemental water quality classification)

Part 2: Definitions

Term	Description
Accretion/accrete	
Adsorption	
Aerenchyma	Specialized thin-walled cells with large air spaces between them to provide buoyancy and support in an aquatic environment (5 – SAV)
Anadromous	Fish species that migrate from the ocean to fresh water streams, lakes, and wetlands to spawn
Anaerobic/reducing	
Anoxia	Absence of oxygen
Anthropogenic	Human-like or caused by humans
Baseflow	
Benthic	Associated with the bottom under a water body
Benthic-pelagic coupling	The influence of the benthic community and sediments on the water column, and in turn, the influence of the water column on the benthic community and sediments, through integrated events and processes such as resuspension, nutrient cycling, settlement, and absorption
Biomass	
Biotic interactions	
Buffer	A vegetated transitional zone between upland areas and aquatic habitats, which functions as a filter of surface water runoff
Catadromous	Fish species that migrate from fresh waters through to spawning areas in the ocean
Catch per unit effort	Amount of fish (numbers or weight) caught by a standard amount of fishing, such as pounds per trip
Compensatory mitigation	
Critical habitat area	Habitat areas that are vital for spawning, early growth and development, and/or the entire life cycleof marine and estuarine fish species (MFC rule 15A NCAC 31 .0101 (20) defines critical habitat areas generally, along with specific definitions for submerged aquatic vegetation, shellfish beds, anadromous fish spawning areas, and anadromous fish nursery areas.)
Strategic Habitat Areas (SHAs)	Specific locations of individual fish habitats or systems of fish habitats that have been identified to provide exceptional habitat functions or that are particularly at risk due to imminent threats, vulnerability, or rarity.
Demersal	Fish species that live primarily on or near the bottom
Denitrification	
Desiccation	
Detritus	Fragments of plant material occurring in the water during the process of decomposition by bacteria and fungi
Detritivores	
Drowned river system	
Dystrophic	Slow flowing streams in the coastal plain, with extensive swamps, bottomland hardwood forest, and marshes in their floodplains; often acidic from high inputs of dissolved organic matter
Embayment	
Emergent vegetation	
Energy regimes	
Epibenthic	
Epibiota	
Estuary	A dynamic coastal water body in which fresh water from rivers and creeks mixes with ocean waters
Estuarine and ocean waters	All the waters of the Atlantic Ocean within the seaward boundary of North Carolina and all the bays, sounds, rivers, and tributaries thereto seaward of the dividing line between coastal fishing waters and inland fishing waters
Euphotic zone	Portion of the water column in which light penetrates sufficiently to allow photosynthesis
Eutrophication	Process of enrichment of a water body with excessive nutrients to the extent that abnormal algae blooms occur and community structure changes
Evapotranspiration	
Extirpation	
Functional equivalence	
Hard bottom habitat	Exposed areas of rock or consolidated sediments, distinguished from surrounding unconsolidated sediments, which may or may not be characterized by a thin veneer of live or dead biota, generally located in the ocean rather than in the estuarine system

Term	Description
Herbivory	
Heterogeneity	
Hydrodynamic conditions	
Hydrogeomorphology	
Hydric soils	
Hypoxia	Condition in which the level of dissolved oxygen in the water column is below that necessary to fully support normal biological functions, resulting in stress for the natural community
Ichthyoplankton	Fish eggs and larvae that drift with the currents near the water's surface
Impoundment	
Interbasin transfers	Artificial movement of water from one river basin to another, generally through pipelines or canals
Inundation	
Isobath	Lines on a map or graph connecting points with the same water depth
Light attenuation	
Light availability	
Macroalgae	Large algae easily visible to the naked eye, such as sea lettuce and kelp
Macrofauna	
Macrophyte	Plant large enough to be visible to the naked eye
Marine systems	Open ocean waters overlying the continental shelf and its associated high-energy coastline where salinities exceed 30 ppt
Meiofauna	Microscopic animals that live in the upper layers of sediment
Meroplankton	Organisms that spend only part of their life cycle in the plankton
Mesohaline	Moderate salinity waters (5-18 ppt)
Nekton	Free-swimming organisms that live in the water column
Oligohaline	Low salinity waters (0.5-5 ppt)
Peat blocks	
Pelagic	Fish species that live primarily up in the water column
Phytobenthic	Refers to microscopic plants that live on the bottom
Phytoplankton	
Plankton	Small organisms that live in the water column, generally near the surface, including eggs, larvae, and adults; they may float with the currents, or have some control over their movements
Polyhaline	High salinity waters (18-30 ppt)
Porewater	
Propagules	A plant seed or spore
Primary production	
Public trust waters	All navigable waters within state jurisdiction and the lands thereunder, below the mean high water line or mean water level
Recruitment	
Rhizomes	Underground plant stem that can give rise to a new plant above the surface
Riparian wetlands	
Sciaenids	Family of fishes that includes the drums and croakers
Sedimentation	
Secondary production	
Sessile	
Silviculture	The branch of forestry dealing with the development and care of forests
Siltation	Process of filling a water body with sediments
Sinks	
slough	
Submersion regime	
Subsidence	
Substrate	
Surface incident light	
Temporal abundance	
Tidal amplitude	Vertical distance between the high and low points of lunar tides
Total suspended solids	
Trophic position	
Trunk estuaries	Coast-perpendicular, drowned river estuaries
Turbidity	Reduced water clarity caused by sediment or other particulates suspended in the water column
Unconsolidated substrate	
Vegetated swales	Very wide ditches with sloping banks constructed to gradually convey storm water to surface waters
Water clarity	A measure of the depth to which light penetrates the water column
Wetlands	
Wind fetch	
Zoogeographical	Related to the geographic distribution of animals

Appendix G: Existing state and federal agency programs that may affect water quality

(From Estuarine Shoreline Protection Stakeholders Report 1999)

Program type	Organization	Program/Policy/Act	Affected Impact	Authority	Geographic Jurisdiction	Issue Permits /Rules	Enforcement	Review Permits	Planning	Technical Assistance	Monitor	Research	Education	Start Year	Reference
Federal Government	Council on Environmental Quality	National Environmental Policy Act	F,N, S,T	S	N	X			X	X				1972	Policy for environmental review of federal projects
	Environmental Protection Agency	Clean Air Act	T,N	S	N	X	X	X	X	X	X	X	X	1970	Regulates air pollution
		Clean Water Act	F,S, N,T	S	N	X	X	X	X	X	X	X	X	1977	Regulates water pollution, provides funds to states for implementation
		Insect, Fungi, & Rodenticide Act	T	S	N	X	X			X	X	X	X	1972	Regulates chemical applications
		Off. Wetlnds, Oceans&Watersheds	F,S, N,T	S,R	N	X	X	X	X	X	X	X	X	1977	Wetland ocean and watershed protection & education
		Oil Pollution Act	T	S	N	X	X		X	X	X	X	X	1990	Mandates more stringent oil spill prevention, response; clean up fund
		Pollution Prevention Act	T	S	N			X	X	X	X		X	1990	Assists industry in pollution prevention measures
		Safe Drinking Water Act	F,S, N,T	S	N	X	X			X	X	?	X	1974	Protects quality of drinking water
	Nat. Oceanic & Atmospheric Adm.	Coastal Non-point Source Prog.	F,N, S,T	S	N				X	X	X			1990	Coordinated state approach to coastal non-point source pollution

* = Federally mandated state program

Geographic jurisdiction
C = 20 coastal counties
S = Statewide
N = National

Affected impacts
F = Fecal coliforms
S = Sediment
N = Nutrient
T = Toxics
Q = Water quality/flow

Appendix H: Status and trends in flow regulation

The status and trends in regulation of flow for North Carolina's coastal rivers are summarized below (adapted from DMF 2002a).

Chowan River Basin

Dams

- One hydropower dam on the Meherrin River in Emporia, Virginia, has effectively blocked anadromous fish movement for over 90 years. For more information, please see the web site (<http://www.sdafs.org/meetings/98sdafs/clupeids/simmonds.htm>). In 1990, a fish elevator or lift was constructed at the Emporia Dam to facilitate migration of American shad and river herring upstream. For more information, please see the web site (<http://www.dgif.state.va.us/fishing/lakes/emporia_reservoir/index.html>). The lift's effectiveness is unknown due to small sample size of tagged individuals recaptured. For information, please see the following web site (<http://www.sdafs.org/meetings/98sdafs/clupeids/simmonds.htm>).
- The lowermost dam on the Nottoway River is the Baskerville Mill Dam, which restricts the historical migratory range of striped bass in that river.

Surface water withdrawal

- There is one municipal intake for Norfolk, Virginia, from Blackwater River; the remainder are only for agriculture. Because small agricultural withdrawals do not need a permit, they are not accounted for in the total water withdrawals.

Roanoke River Basin

Dams

- There are several large dams upstream of Roanoke Rapids, including the Lake Gaston Dam, John H. Kerr Dam, Hyco Dam, Mayo Dam, Smith Mountain Lake Dam, Leesville Dam, Philpott Lake Dam, Avalon Dam and Pinnacles Dam (DWQ 2001c; Pearsall et al. [no date]; <www.rrba.org/facts.htm>). Completed in 1952 and operated by the U.S. Army Corps of Engineers (COE), the Kerr Dam created the largest reservoir in the system, covering approximately 48,900 ac (19,789 hectares) (<http://epec.saw.usace.army.mil/kerrdesc.txt>). The Roanoke Rapids Dam is the lowermost dam on the main stem of the river, and there are no power plants downstream of its location. Numerous small municipal water supply dams and old mill dams exist on the river's tributary streams.

The Roanoke River Water Flow Committee

- The Committee, including state and federal government representatives, academics, local officials and residents, and corporate interests, was established in 1988 to address flow issues. A new flow regime was developed and implemented during striped bass spawning periods, which, along with state fishery management efforts, has resulted in greatly improved juvenile striped bass recruitment (Manooch and Rulifson 1989). However, outside of the striped bass spawning period (April 1–June 15), flows remain altered by hydropower peaking operations. New FERC license for Gaston and Roanoke Rapids dams will expand the spawning period into March.

Surface water withdrawal

- There are 26 registered water withdrawals in the North Carolina portion of the basin. Of these, 16 are surface water withdrawals (DWQ 2001c).
- Water supply demand is expected to increase greatly within the basin, and other basins are also considering the river as a potential water supply source. Withdrawal for power

plant use accounts for the majority of the water volume removed, although most is eventually returned to the system.

Tar-Pamlico River Basin

Dams

- Tar River Dam/ Reservoir controls downstream releases; the reservoir is water supply for the city of Rocky Mount.
- Rocky Mount Mills Dam, a hydropower facility, is the lowermost dam on the Tar River. It is an obstruction to migrating striped bass, American shad, hickory shad, and blueback herring during the spring spawning season (Collier and Odom 1989) (Map 2.11).

Surface water withdrawal

- There are several municipal surface water withdrawals (including Enfield, Greenville, Louisburg, Rocky Mount, Tarboro) and numerous agricultural withdrawals.
- Of the 60 water withdrawals registered in the basin (39 agricultural, 21 non-agricultural), 51 are surface water withdrawals (DWQ 2003).
- Surface water withdrawals are projected to increase because of demand and because the basin is partially located within the Central Coastal Plain Capacity Use Area (CCPCUA). Ground water use within the CCPCUA, so demand for surface water as a replacement source will grow.

Neuse River Basin

Dams

- Removal of Quaker Neck Dam in 1998 opened access to 74 additional miles of upstream river habitat for migrating anadromous fish each spring.
- Milburnie Dam, a small hydropower facility near Raleigh, is now the lowermost dam on the Neuse River (Map 2-11).
- Falls Dam/Reservoir is managed by the COE for flood control, municipal water supply, water quality enhancement downstream, and recreation. Currently, discussions are underway between WRC and COE to stabilize downstream flows to benefit spawning by anadromous species in the Neuse River.

Surface water withdrawal

- There are numerous agricultural and municipal water supply withdrawals from the main stem of the river, as well as from many of its tributaries, including the cities of Durham, Raleigh, Smithfield (in addition to a separate intake for Johnston County), Goldsboro, and Wilson.
- Surface water withdrawals are projected to increase due to demand. The CCPCA rules will also affect portions of this river basin, including Carteret, Craven, Jones, Lenoir, Pamlico, Pitt, Wayne, and Wilson counties. As of 2003, an application was in process for withdrawal of 60 million gallons per day from the Neuse River in Lenoir County to replace existing ground water supplies.
- Of the 176 registered water withdrawals in the Neuse River basin, excluding 78 public water systems, 51 are surface water withdrawals (DWQ 2002).

Cape Fear River Basin

Dams

- The three COE Lock and Dams, constructed for navigation between 1915 and 1934 (Moser et al. 2000), are the lowermost obstructions to fish passage. However, in 1997,

efforts to improve anadromous fish passage were made at Lock #1, including the use of fish-locking cycles or lockage to facilitate fish migration during the spawning period and the construction of a steppass Denil fishway (Moser et al. 2000). Sonic tracking of American shad revealed varying proportions (ranging from 18% in 1997 to 63% in 1998) of successful upstream passage of tagged individuals during Lock # 1 operation (Moser et al. 2000). By way of comparison, passage efficiency of adult shad was relatively lower at the fishway (Moser et al. 2000). In general, efficiency of fish passage was improved by a) increasing the frequency of lockage events per day, b) extending lockage duration to include more of the spawning season, and c) encouraging fish entrance into the lock via attractant flows (Moser et al. 2000). Buckhorn Dam is the lowermost complete barrier to fish migration. Striped bass tagged by DMF in the lower Cape Fear River near Wilmington have been recaptured just below this obstruction. Although the hydropower facility at the Buckhorn Dam no longer operates, the dam continues to provide a pool for cooling water for a nearby coal-fired power plant.

- B. Everett Jordan Dam/Reservoir is located well upstream of the lock and dam system. It provides water for Holly Springs, Apex, Cary, Durham, Morrisville, and Chatham, Orange, and Wake counties. (<www.ncwater.org/ReportsandPublications>).

Surface water withdrawal

- There are numerous municipal water withdrawals, and they are the largest threat to instream flow in the Cape Fear river basin.
- In 1999, there were 57 registered water withdrawals in the basin (DWQ 2000c).
- Surface water withdrawals are projected to increase 39% by 2010, excluding new permitted withdrawals. Municipalities dependent on water withdrawals include Cary, Apex, Orange County, Wake County – Research Triangle Park, Fayetteville, Fort Bragg, Wilmington, and the lower Cape Fear Water and Sewer Authority.

Draft

Appendix I: Effects of environmental pollutants on fish early life stages [exp. = exposure; from Weis and Weis (1989), Key et al. (2000)]

Chemicals	Effect on fish			Water quality standards (ug/l)	
	Test organism	Test	Results	Salt-water aquatic life	Fresh-water aquatic life
Benzo[a] Pyrene (B[a]P)					
Methylmercury	Mummichog	unspecified exp.	Abnormal cell division of embryos		
Chlorine					
Chlorine, total residual	Striped bass	0.07 mg/l exp.	3.5% of embryos hatched and malformation of surviving hatchlings	na	17 (AL)
		0.01 mg/l exp.	23% of embryos hatched		
		0.15 mg/l exp.	Embryo mortality noted in combination with temperature change of 2°C.		
	Spotted seatrout	unspecified exp.	Greater resistance of embryos than larvae		
	Striped bass, white perch, blueback herring, silversides	0.3 mg/l exp.	Lethal to embryos		
Herbicides					
Atrazine	Channel catfish	0.4 mg/l exp.	Embryo deformities		na
Diquat	Mummichog	0.01-10mg/l exp.	Fry neurologically impaired after embryo exposed		
Trifluraline	Sheepshead minnow	unspecified exp.	Embryo deformities		
PCBs					
Aroclor 1016	Sheepshead minnow	>32 ug/l exp.	Total mortality of embryos and fry		
Aroclor 1242	Fathead minnow	<5.4 ug/l exp.	No effect on embryos		
Aroclor 1254	Sheepshead minnow	10 ug/l exp.	Reduced survival rate of embryos		
		>0.1 ug/l exp.	Reduced fry survival		
		0.14 ug/l exp.	Adult exposure and reduced survival of embryos and fry		
Pesticides					
Aldicarb (Temik)	Fathead minnow	<320 ug/l exp.	No effect		
	Fathead minnow	156 ug/l exp.	100% larvae mortality in 30-day test		
Carbaryl (Sevin)	Silversides	10 ug/l exp.	Embryo malformations		
	Killifish	10 ug/l exp.	Arrested embryo development, embryos transferred to clear water after continous exp. had abnormalities		

Chemicals	Effect on fish			Water quality standards (ug/l)	
	Test organism	Test	Results	Salt-water aquatic life	Fresh-water aquatic life
DDT	Killifish	1mg/l exp.	Hatchlings with tail deformities	0.001	0.001
		0.1 ug/l exp.	Slowed development of embryos		
	Silversides	25 ug/l exp.	Embryo malformations		
	Yellow perch	unspecified exp.	No fin ray asymmetry		
Dieldrin	Winter flounder	>1.74 ng/g eggs	Eggs not fertilized	0.0002	0.002
		39 ug/l exp.	50% mortality		
Endrin	Sheepshead minnow	0.31 ug/l	Embryo stunting, some mortality, and lower fertility of adults	0.002	0.002
Fenoprop (Kuron)	Bluegill	>10 ug/l exp.	100% mortality of hatchlings		
Fenvalerate	Sheepshead minnow	3.9 ug/l exp.	Reduced hatchling survival		
	Fathead minnow	0.43 ug/l exp.	Unspecified negative effect on larvae		
Fonofos	Fathead minnow	<80 ug/l exp.	No effect		
		33 ug/l exp.	100% larvae mortality in 30-day test		
Kelthane (Dicophol)	Fathead minnow	125 ug/l exp.	Delayed and reduced hatching, survivors deformed and died		
		39 ug/l exp.	50% mortality		
Kepone	Sheepshead minnow	1.9 ug/l exp.	16% arrested development of embryos		
	Fathead minnow	0.31ug/l exp.	Reducing hatching success		
Lindane	*Caranx*	unspecified exp.	Premature hatching and fry deformaties	0.004	0.01
Malathion	Silversides	10 ug/l exp.	Embryo malformations		
Methoxychlor	Winter flounder	>1.74 ng/g eggs	Eggs not fertilized	0.03	0.03
		39 ug/l exp.	50% mortality		
Mirex	Fathead minnow	2,3,7 ug/l exp.	Increased viability of hatchlings	0.001	0.001
		13,34 ug/l exp.	No effect		
Parathion	Mummichog	10 ug/l exp.	Arrested embryo development, 50% of embryos exposed for 3 days and returned to clean water had malformations	0.178	0.013
	Mummichog	1 ug/l exp.	Few malformations after 3 day exp.		
Permethrin	Sheepshead minnow	22 ug/l exp.	Reduced hatchling survival		
		2.2 ug/l exp.	Reduced hatchling size		
Permethrin biomist	Gambusia	25,114 mg/l	48 h LC_{50}		

Chemicals	Effect on fish			Water quality standards (ug/l)	
	Test organism	Test	Results	Salt-water aquatic life	Fresh-water aquatic life
Permethrin-Permanone	Gambusia	0.0027 mg/l	48 h LC_{50}		
Pyrethroids	Sheepshead minnow	0.06 ug/l exp.	Reduced fish weight		
Temephos	Gambusia	0.014-0.039 mg/l	48 h LC_{50}		
Petroleum hydrocarbon					
Toluene	Fathead minnow	30-45 mg/l exp.	Embryonic malformations	na	11
Water soluable fraction of No. 2 fuel oil	Mummichog	unspecified exp.	Malformation of larvae and decreased time to hatching of embryos, increased toxicity noted at suboptimal water conditions		
	Mummichogs, sheepshead minnow	12 ppm	100% mortality of hatchlings		
		6 ppm	50% mortality of hatchlings		
		1,4 ppm	Stimulated hatching		
Wood preservative					
Pentachlorophenol	Fathead minnow	128 ug/l exp.	Reduced larval survival		
		>73 ug/l exp.	Reduced growth of larvae		

Appendix J. Land protection and conservation opportunities in the North Carolina coastal river basins by eligible land types and conservation techniques (DENR 1999). Eligible land types include agricultural (A), forested (F), wetlands (W), prior converted wetlands (PCW), riparian areas (R), and residential (RES).

APPENDIX K:

NORTH CAROLINA MARINE FISHERIES COMMISSION

POLICIES FOR THE PROTECTION AND RESTORATION OF MARINE AND ESTUARINE RESOURCES FROM BEACH DREDGING AND FILLING AND LARGE-SCALE COASTAL ENGINEERING

NORTH CAROLINA MARINE FISHERIES COMMISSION HABITAT AND WATER QUALITY STANDING ADVISORY COMMITTEE: NOVEMBER 6, 2000 NORTH CAROLINA MARINE FISHERIES COMMISSION: NOVEMBER 16, 2000

Policy Context

This document establishes the policies of the North Carolina Marine Fisheries Commission (Commission) regarding protection and restoration of the state's marine and estuarine resources associated with beach dredge and fill activities, and related large-scale coastal engineering projects. The policies are designed to be consistent with the overall habitat protection policies of the Commission, adopted April 13, 1999, as amended February 17-18, 2000, as follows:

> It shall be the policy of the North Carolina Marine Fisheries Commission that the overall goal of its marine and estuarine resource protection and restoration programs is the long-term enhancement of the extent, functioning and understanding of those resources.
>
> Toward that end, in implementing the Commission's permit commenting authority pursuant to N.C.G.S. §143B-289.52(a)(9), the Chairs of the Habitat and Water Quality Standing Advisory Committee, in consultation with the Commission Chair, shall, to the fullest extent possible, ensure that state or federal permits for human activities that potentially threaten North Carolina marine and estuarine resources:
>
> (1) are conditioned on (a) the permittee's avoidance of adverse impacts to marine and estuarine resources to the maximum extent practicable; (b) the permittee's minimization of adverse impacts to those resources where avoidance is impracticable; and (c) the permittee's provision of compensatory mitigation for all reasonably foreseeable impacts to marine and estuarine resources in the form of both informational mitigation (the gathering of base-line resource data and/or prospective resource monitoring) and resource mitigation (in kind, local replacement, restoration or enhancement of impacted fish stocks or habitats); and
>
> (2) result, at a minimum, in no net loss to coastal fisheries stocks, nor functional loss to marine and estuarine habitats and ecosystems.

The findings presented below assess the marine and estuarine resources of North Carolina which are potentially threatened by activities related to the large-scale movement of sand in the coastal ocean and adjacent habitats, and the processes whereby those resources are placed at risk. The policies established in this document are designed to avoid, minimize and offset

damage caused by these activities, in accordance with the laws of the state and the general habitat policies of this Commission.

Marine and Estuarine Resources At Risk from Beach Dredge and Fill Activities

The Commission finds:

1) In general, the array of large-scale and long-term beach alteration projects currently being considered for North Carolina together constitute a real and significant threat to the marine and estuarine resources of the United States and North Carolina.

2) The cumulative effects of these projects have not been adequately assessed, including impacts on public trust marine and estuarine resources, use of public trust beaches, public access, state and federally protected species, state critical habitats and federal essential fish habitats.

3) Individual beach dredge-and-fill projects and related large-scale coastal engineering activities rarely provide adequate assessment or consideration of potential damage to fishery resources under state and federal management. Historically, emphasis has been placed on the logistics of sand procurement and movement, and economics, with environmental considerations dominated by compliance with limitations imparted by the Endangered Species Act for sea turtles, piping plovers and other listed organisms.

4) Opportunities to avoid and minimize impacts of beach dredge-and-fill activities on fishery resources, and offsets for unavoidable impacts have rarely been proposed or implemented.

5) Large-scale beach dredge and fill activities have the potential to cause impacts in four types of habitats:

   a) waters and benthic habitats near the dredging sites;
   b) waters between dredging and filling sites;
   c) waters and benthic habitats near the fill sites; and
   d) waters and benthic habitats potentially affected as sediments move subsequent to deposition in fill areas.

6) Certain nearshore habitats are particularly important to the long-term viability of North Carolina's commercial and recreational fisheries and potentially threatened by large-scale, long-term or frequent disturbance of sediments:

   a) inlets;
   b) the swash and surf zones and beach-associated bars; and
   c) underwater soft-sediment topographic features, both onshore and offshore underwater hard-substrate topographic features.

7) Large sections of North Carolina waters potentially affected by these projects, both individually and collectively, have been identified as Essential Fish Habitats (EFH) by the

South Atlantic Fishery Management Council (SAFMC) and the Mid-Atlantic Fishery Management Council (MAFMC). Affected species under federal management include:

a) summer flounder (various nearshore waters, including the surf zone and inlets; certain offshore waters);
b) bluefish (various nearshore waters, including the surf zone and inlets);
c) red drum (ocean high-salinity surf zones and unconsolidated bottoms to a depth of 50 meters);
d) several snapper and grouper species (live hard bottom from shore to 600 feet, and – for estuarine-dependent species [e.g., gag grouper and gray snapper] – unconsolidated bottoms and live hard bottoms to the 100 foot contour);
e) spiny dogfish (various coastal waters from the surf zone to 200 miles);
f) black sea bass (various nearshore waters, including unconsolidated bottom and live hard bottom to 100 feet, and hard bottoms to 600 feet);
g) penaeid shrimps (offshore habitats used for spawning and growth to maturity, and waters connecting to inshore nursery areas, including the surf zone and inlets);
h) coastal migratory pelagics (sandy shoals of capes and bars, barrier island and ocean-side waters from the surf zone to the shelf break inshore of the Gulf Stream; all coastal inlets);
i) corals of various types (hard substrates and muddy, silty bottoms from the subtidal to the shelf break);
j) calico scallops (unconsolidated bottoms northeast and southwest of Cape Lookout in 62-102 feet);
k) sargassum (wherever it occurs out to 200 miles);
l) many large and small coastal sharks, managed by the Secretary of the Department of Commerce (inlets and nearshore waters, including pupping and nursery grounds).

8) Beach dredge and fill projects also potentially threaten important fish habitats for anadromous species under federal, interstate and state management (in particular, inlets and offshore overwintering grounds), as well as essential overwintering grounds and other critical habitats for weakfish and other species managed by the Atlantic States Marine Fisheries Commission and the State of North Carolina. The SAFMC identified for anadromous and catadromous species those habitats that have been EFH if there had been a council plan (inlets and nearshore waters).

9) Many of the habitats potentially affected by these projects have been identified as Habitat Areas of Particular Concern by the SAFMC. The specific fishery management plan is provided in parentheses:

a) all nearshore hard bottom areas (SAFMC, snapper-grouper);
b) all coastal inlets (SAFMC, penaeid shrimps, red drum, and snapper-grouper);
c) near-shore spawning sites (SAFMC, penaeid shrimps, and red drum)
d) well-known seafloor features, including the Point, Ten Fathom Ledge and Big Rock (SAFMC, snapper-grouper, coastal migratory pelagics, and corals);
e) pelagic and benthic sargassum (SAFMC, snapper-grouper);

f) sandy shoals of Cape Lookout, Cape Fear, and Cape Hatteras (SAFMC, coastal migratory pelagics) and;
g) Bogue Sound and New River Estuary (SAFMC, coastal migratory pelagics).

10) Habitats likely to be affected by beach dredge and fill projects include many being recognized in North Carolina Fishery Management Plans as important for state-managed species. Many of these habitats are in the process of being recognized as Critical Habitat Areas by the Commission, in either FMPs or in Coastal Habitat Protection Plans. Examples include:

a) inlets (Blue Crab FMP, Red Drum FMP, River Herring FMP);
b) oceanic nearshore waters (Blue Crab FMP, Red Drum FMP); and
c) many others as FMPs and CHPPs are adopted over the coming years.

11) Recent work by scientists in east Florida has documented exceptionally important habitat values for nearshore, hard-bottom habitats often buried by beach dredging projects, including use by over 500 species of fishes and invertebrates, and juveniles of many reef fishes. Equivalent scientific work is just beginning off North Carolina, but life histories suggest that similar habitat use patterns will be found.

Threats to Marine and Estuarine Resources from Beach Dredge and Fill Activities

The Commission finds that beach dredge-and-fill activities and related large-scale coastal engineering projects (including inlet alteration projects) threaten the marine and estuarine resources of North Carolina through the following mechanisms:

1) Direct mortality and displacement of organisms at and near sediment dredging sites;
2) Alteration of seafloor topography and associated current and waves patterns and magnitudes at dredging areas;
3) Alteration of seafloor sediment size-frequency distributions at dredging sites, with secondary effects on benthos at those sites;
4) Elevated turbidity and deposition of fine sediments down-current from dredging sites;
5) Direct mortality and displacement of organisms at initial sediment fill sites;
6) Elevated turbidity in and near initial fill sites, especially in the surf zone, and deposition of fine sediment down-current from initial fill sites;
7) Alteration of near-shore topography and current and waves patterns and magnitudes associated with fill;
8) Movement of deposited sediment away from initial fill sites, especially onto hard bottoms;
9) Alteration of large-scale sediment budgets, sediment movement patterns and feeding and other ecological relationships, including the potential for cascading disturbance effects;
10) Alteration of large-scale movement patterns of water, with secondary effects on water quality and biota;
11) Alteration of movement patterns and successful inlet passage for larvae, post-larvae, juveniles and adults of marine and estuarine organisms;
12) Alteration of long-term shoreline migration patterns (inducing further ecological cascades with consequences that are difficult to predict); and

13) Exacerbation of transport and/or biological uptake of toxicants and other pollutants released at either dredge or fill sites.

Commission Policies for Beach Dredge and Fill Projects and Related Large Coastal Engineering Projects

The Commission establishes the following general policies related to large-scale beach dredge-and-fill and related projects, to clarify and augment the general policies already adopted on April 13, 1999:

1) Projects should fulfill the Commission's general habitat policy by avoiding, minimizing and offsetting damage to the marine and estuarine resources of North Carolina;

2) Projects should provide detailed analyses of possible impacts to each type of Essential Fish Habitat (EFH), with careful and detailed analyses of possible impacts to Habitat Areas of Particular Concern (HAPC) and Critical Habitat Areas (CHA), including short and long term, and population and ecosystem scale effects;

3) Projects should provide a full range of alternatives, along with assessments of the relative impacts of each on each type of EFH, HAPC and CHA;

4) Projects should avoid impacts on EFH, HAPCs and CHAs that are shown to be avoidable through the alternatives analysis, and minimize impacts that are not;

5) Projects should include assessments of potential unavoidable damage to marine resources, using conservative assumptions;

6) Projects should be conditioned on the avoidance of avoidable impacts, and should include compensatory mitigation for all reasonably predictable impacts to the marine and estuarine resources of North Carolina, taking into account uncertainty about these effects. Mitigation should be local, up-front and in-kind wherever possible;

7) Projects should include baseline and project-related monitoring adequate to document pre-project conditions and impacts of the projects on the marine and estuarine resources of North Carolina;

8) All assessments should be based upon the best available science, and be appropriately conservative so as to be prudent and precautionary; and

9) All assessments should take into account the cumulative impacts associated with other beach dredge-and-fill projects in North Carolina and adjacent states, and other large-scale coastal engineering projects that are ecologically related.

Draft

Appendix L. Impacts to fish habitat from commercial and recreational fishing gears used in coastal North Carolina (adapted from Moratorium Steering Committee (1996)).

Fishing method	Habitat impacts and recommendations
Bay Scallop Dredge: A fairly lightweight (not>50 lbs.) steel frame, without teeth, used in estuarine waters, and that has an attached, nylon webbing bag to accumulate the catch.	The use of patent tongs is thought to have a major effect on shellfish beds and the bottom generally. Recommend collection of information on this gear, e.g., the habitat impact experiences of other states which have or are presently allowing use of patent tongs.
Beach Seine: Net generally used to corral mullets. A beach seine can also be used on such fish as striped bass and spot. Sometimes a beach seine is used in conjunction with a "stop" net. Net usually spread round fish with a boat and then pulled to the shore. Pulling power can be by hand or by vehicle. This is one of the most historic methods of fishing.	No known habitat impacts. No recommendations at this time.
Bull Rake: A large, heavy clam rake, usually having eighteen (18) to twenty-eight (28) teeth. Handles range from ten (10) feet to forty (40) feet long.	Bull rakes have severe habitat impacts when used on oyster rocks, and can damage SAV beds. Recommend that bull rake clamming on marked oyster grounds and SAV beds be prohibited.
Butterfly Trawl: In this gear, a solid frame holds a modified trawl in the top of the water column, acting like a channel net. Its use generally requires a good tidal flow and it is normally used only at night.	Little known habitat impact. Skimmer trawls are generally okay to use in SAV beds, but should not be used in oyster grounds. Recommend that trawls be prohibited in marked oyster grounds and that the more widespread use of this gear be promoted in estuarine waters.
Cast Net: Small net thrown by hand and used to catch "schooled fish", such as mullet, and used by bait-fish dealers and individual fishermen to net bait-fish and shrimp.	No known habitat impacts. No recommendations at this time.
Channel Net: A passive gear built like a shrimp trawl that is anchored in a specific area. Channel nets are used to catch shrimp in areas with strong tidal flow, which is required to hold the net open.	No known habitat impacts. No recommendations at this time.
Clam Kickers: Generally refers to the use of the propeller of a boat to blow the mud/silt off the clams and into a trawl having a heavy steel cage or bag made of rings. The gear is chained so that it plows up the clams as it is towed behind the vessel. Often the stern of the vessel is loaded so that the propeller "wash" is directed at a downward angle.	The use of this gear has severe impacts upon SAV beds and oyster grounds. Recommend that areas that may be used by these dredges not be expanded in public trust areas. However, employment in mariculture operations to recover shellfish crops should be considered a viable use of the gear if leases are located in an area where the gear is already allowed, if adjacent leases would not be affected. Permits should be issued by the division of Marine Fisheries on a case-by-case basis. During the oyster season, legal size oysters caught incidental to clamming should be allowed to be retained.
Clam Tongs: Hand held steel "forceps", used to recover clams from any and all types of bottom. Clam tong teeth tend to be longer and more closely spaced than the teeth on oyster tongs.	Habitat impacts of oyster dredges can be significant. Historically, such dredges have been used only on bottoms that were oyster beds. Dredges can plow down any mounds of shellfish and should not be allowed for use in SAV beds. Recommend maintaining present limits on usage and that steps be taken to ensure that the gear is used with adequate consideration of its habitat impacts.
Crab Dredges: A crab dredge is much like an oyster dredge, except perhaps with longer teeth, and is used to dredge crabs from the bottom sediments during the winter months. Crab dredges are used in northern North Carolina waters from Long Shoal north.	Habitat impacts from the use of crab dredges can be significant, and the gear causes severe damage on oyster grounds or in SAV beds. Recommend that the current restrictions on the use of this gear be maintained, and that steps be taken to ensure that crab dredges are used with adequate regard to their effects on coastal fishery habitats.

Fishing/method	Habitat/Impacts and Recommendations
Crab Pot: A wire trap similar to a fish pot. This is the usual method for catching crabs in North Carolina.	Very little habitat impact. Main habitat impact is from discarded bait cartons. It is generally okay to use crab pots in SAV beds, PNAs , or oyster grounds. Anecdotal reports indicate the use of anti-fouling solution or "cleansing" solutions aboard boats or near the waters edge to treat crab pots. Also anecdotal evidence exists to indicate that zinc used in crab pots to minimize rusting may contribute to heavy metal pollution in estuarine systems. Recommend: (1) a requirement that bait boxes be returned to shore; (2) a requirement that biodegradable escape panels be used in crab pots [Note: There is work being done that indicates that "tagged" crabs left in a crab pot with no food subsequently appear in other baited pots]; (3) prohibition of the use of any anti-fouling solution aboard a vessel or within seventy-five (75) feet of the shoreline; and (4) a study of the effects of zinc used to coat crab pots in terms of estuarine pollution.
Crab Trawl: A trawl consisting of larger mesh nets made like a shrimp trawl. The basic equipment is the same as a shrimp trawl except that the bottom leading edge of the trawl is laced with several loops of heavy chain so that the crabs are "plowed" out of the bottom where they have embedded themselves.	For all bottoms, the severity of habitat impacts from the use of shrimp trawls is related to the size of the doors. Damage to oyster grounds is generally moderate to high. Studies are inconclusive on the question of whether trawling in other areas has significant habitat impacts. Recommend continuation of prohibition of trawling in marked oyster grounds. A study of the impact of trawling on different types of habitat should also be conducted.
Dip Nets/Pier Net: Hand nets that are not usually used to catch fish by themselves, but rather, are used as tools in conjunction with other fishing gears. For example, a flounder fisherman may use a dip net to scoop up a flounder that is in his net but appears ready to fall out, or a fisherman may use a pier net to bring up catches of mullet too large to lift without danger of splitting his cast net, or to lift other species to keep from breaking the line of his fishing rod. However, large dip nets are used to catch river herring and shad in coastal streams.	No known habitat impacts. No recommendations at this time.
Eel Pot: A wire trap that looks like a crab pot, but has smaller wire mesh.	No known habitat impacts. If escape panels are used, the lost pots become habitat. Okay to use in SAV beds or oyster grounds. Recommend that biodegradable escape panels be required for eel pots.
Electric Shocking: Refers to the use of mechanical devices that generate an electric current into coastal fishing waters, which stun the fish and cause them to rise to the surface. The practice of electric shocking is currently allowed only in a portion of the Cape Fear River, where it is used to catch catfish.	Habitat effects on this practice are unknown, but would seem to potentially be significant. Recommend that this practice continue to be prohibited in North Carolina.
Estuarine Gill Net: A major gear used in North Carolina's internal coastal waters that captures fish by entangling them when they swim into the net. The next is often anchored to the bottom or attached to stakes. In some fisheries, gill nets are fished by drifting with the current. A variety of mesh sizes are used to take spot, flounder, American shad, river herring, mullet, striped bass and many other species. This gear is often used by recreational fishermen.	Estuarine gill nets have negligible habitat impacts. Such gear can be safely used in PNAs, SNAs and SAV beds. Proper identification of gear owners should be emphasized, along with regular tending of the fear to avoid wastage of fish. No recommendations at this time.
Explosives: Pyrotechnic devices, such as dynamite, used to create a concussion, which causes the stunned or dead fish to rise to the surface where they are gathered. The use of explosives to fish is not legal in North Carolina	No known habitat impacts. No recommendations at this time.
Fish Pot: A wire trap having directed (one-way) openings whereby fish may enter to get to bait. Fish pots are generally used in the ocean harvesting of black sea bass. Fish pots are also used to harvest catfish in the Albemarle Sound area.	Very little habitat impact. Impact can increase in coral formations. "Lost" pots become habitat when used correctly with biodegradable panels. Pots in estuarine waters do not adversely affect oyster grounds or SAV beds. Recommend that biodegradable escape panels be required for all fish pots.
Fish Trawls/Flynets: Usually large trawl nets, generally fished in ocean waters. Fish trawls may drag on the bottom, but also may utilize "mid-water technology." Fish trawling is not allowed in inside waters in North Carolina.	No known habitat impacts, but complaints have been received of float nets being used in a manner that blocks navigation channels, and of failure to yield to boat traffic. Recommend that float netters be required to yield to boat traffic.
Float Netting: This is done when a shrimp trawler "floats" its doors so that it can act as a butterfly or channel net, usually occurring in ebb tidal flow and at night.	No known habitat impacts, but there have been complaints that these netters have failed to yield to boat traffic when working the Atlantic Intracoastal Waterway and marked channels. Recommend that the use of butterfly trawls be promoted, with a requirement that netters must yield to all boat traffic when utilizing navigation channels

Fishing method	Habitat impacts and Recommendations
Fyke Net: A usually round net having a series of throats. Tyke nets are primarily used in the upper reaches of estuaries.	No known habitat impacts. No recommendations at this time.
Gig: A spear with or without barbed points at its tip, used mostly to spear flounder at night, using underwater lights.	No known habitat impacts. No recommendations at this time.
Hand Clam Rake: A tool that usually has nine (9) teeth or less, and looks a lot like a garden rake. Most rakes have a handle, but they can consist merely of "metal fingers" that rest at the wrist and extend over the fingers. Clam rakes can be utilized to "scratch" for clams under water or for "signing" on tidal flats at low tide.	Very little habitat impact in most areas, but slight impacts occur in SAV beds. Clam rakes are difficult to use on most oyster rocks, but impact can be great when used to pull oysters into piles in order to get at the clams beneath. Recommend that: (1) no rakes be allowed in marked oyster rocks/beds {these oyster areas would be designated "clam seed management areas"}; and (2) during the normal oyster season, clams should be allowed as an unlimited, approved, incidental catch when harvesting oyster.
Hand Clamming: Refers to the clamming method wherein clammers are in the water on their hands and knees feeling for clams. Clammers typically use latex gloves as protection for their hands, but can use the "metal hands" noted under "Clam Rake", above.	Very little known habitat impact. Hand clamming in generally okay in SAV beds. Recommend that hand clamming on marked oyster grounds be prohibited except as part of the normal oyster season.
Hand Seine: Small mesh net used to catch bait. Usually pulled by hand, but sometimes a boat is used to spread the seine.	No known habitat impacts. Recommend increasing allowable hand seine sizes to thirty (30) feet.
Hook and Line: The customary "rod and reel" method of fishing, used as the "up and down" bottom rig in the reef fish fishery. "Electro-mate" reels are customarily used for rapid line retrieval.	Virtually no habitat impacts, but see comments at right on monofilament fishing line and other relevant equipment. No recommendations at present.
Hydraulic Clam Dredge: Gear generally used to harvest clams, that employs a conveyer system that can be lowered to the bottom where jets of water uncover the clams. These dredges are allowed only in "mechanical clamming" areas. The gear is also used by mariculturists to harvest shellfish crops from their public bottom leases.	The use of purse seines has no habitat impacts as the net is fished entirely within the water column. No recommendations at this time.
Long haul seine: Usually a long seine, heavily leaded (weighted) and dragged by boats in estuarine waters to catch fish.	Some damage to SAV beds may occur from the heavily leaded bottom line being dragged through the grass beds. Damage to SAV beds by the boat motor propellers may be significant in shallow waters. There is concern over the use of this gear in PNAs (where use is currently prohibited) and near oyster rocks. Recommend: (1) a study be implemented to determine the actual bottom damage and whether the damage is short-term or long-lasting; (2) all oyster grounds, PNAs, and SAV beds be permanently marked: and (3) a study be conducted into the effects of long haul seine activities in these areas.
Long-line System: Fishing lines used for top-water, underwater or bottom fishing.	Virtually no habitat impacts when used as a top-water gear. Impact of bottom gear can range from minor on sand bottoms to significant when used in live rock (coral) formations. Recommend that bottom gear should be prohibited in coral formations.
Ocean Drift Net: Usually a monofilament gill net constructed so as to be tended from the top down. Ocean drift nets generally utilize a larger mesh size than bottom fishing nets. There is very little, if any, use of this gear in the ocean off North Carolina.	No known habitat impacts. No recommendations at this time.
Ocean Sink Gill Net: These are offshore gill nets that may be heavily anchored or not, as is appropriate to the area and fishery.	Sink nets have very little habitat impact unless gear becomes entangled with live rock formations. Lost or discarded webbing can become a danger for continued fishing until webbing becomes encrusted. Recommend better, more positive identification of net owners.
Otter Trawl: A cone-shaped net fashioned in one of the many patterns of "Otter Trawls", used primarily in North Carolina to catch shrimp. The gear is pulled from behind or alongside a vessel using "doors" or "gates" to keep the trawl open. The doors are sized (18" x 36" to 40" x 120") and weighted (50 lb. to 500 lb.) in direct ratio to the size of the trawl. Trawls skim the bottom, and shrimp are made to "pop" up into the net by a "tickler" chain pulled just ahead of the bottom line. Trawl doors ride along the bottom.	
Oyster Dredge: Usually heavy, large-toothed cages towed by a vessel to recover oysters from deeper waters. Oyster dredges are currently allowed only in Pamlico Sound, with a one hundred-(100) pound weight limit.	These dredges have severe habitat impacts. Recommend that dredges continue to be prohibited in estuaries and on live bottom formations offshore [Note: This fishery is regulated under a federal FMP, and its impacts are not presently an issue in NC].

Fishing method	Habitat impacts and Recommendations
Oyster Tongs: Hand held steel "forceps", typically used while standing in a boat to recover oysters from water ranging in depth from that barely deep enough to float a boat to then 910) to twelve (12) feet.	Some habitat impact in SAV beds. Impacts on oyster beds may be negated if clam and oyster seasons are combined at some future point. Recommend that clam tongs be prohibited on marked oyster rocks except during oyster harvest season.
Patent Tongs: Very large steel "forceps" typically used to recover oysters from deep water.	The use of clam kicking has severe habitat impact on all bottoms. The gear causes severe damage to SAV beds and to oyster rocks. Recommend that gear continue to be prohibited in SAV beds and over marked oyster grounds.
Pound Net: A passive gear using netting "leads", which the fish travel along to a net "pound", where they are captured. Captured fish can be culled alive. Mesh size in the pound can be fish size selective. This gear known also as "weirs", and is one of the oldest methods of fishing. Some states have specific laws protecting weirs.	No known habitat impacts. The poles used to support the pound net leads and pound are permanent structures that can themselves become habitat, but abandoned or broken-off poles can become a hazard to navigation. No recommendations at this time.
Purse Seine: Large net used to catch menhaden. A menhaden school is surrounded by the purse et and a large weight is then dropped to close, or "purse", the bottom of the net.	
Sea Scallop Dredge: An extremely heavy steel cage similar to an oyster dredge that drags the bottom and is used in the ocean. These dredges are intended for use only on beds of scallops at sea.	Very little habitat impact. It is generally okay to use these dredges in SAV beds over a short scallop season. No recommendations at this time.
Shrimp Pot: A wire trap used as a special type of underwater trap or pot to catch shrimp.	No known habitat impacts. Okay to use in SAV beds, PNAs, or oyster grounds. No recommendations at this time.
Skimmer Trawl: A trawl net that utilizes a solid frame and a flat offshore "foot" in order to push a trawl through the water without using doors. Use of this gear is limited to areas where the depth of the water is no more than the size of the metal frame. Its use is highly successful in the "white shrimp" fishery.	The use of crab trawls has severe impacts on all bottoms, causing great damage to oyster grounds and moderate to severe damage in SAV beds. Crab trawling results in substantial sedimentation in the trawled area. Recommend that crab trawls be prohibited in marked oyster grounds. Because of heavy chain at the mouth of these trawls, there was much concern over potential damage to SAV beds. For that reason, also recommend a study of the effects of crab trawling on SAV beds.
Spear: Similar to a gig, but usually single pronged, used by underwater divers using scuba gear.	No known habitat impacts. No recommendations at this time.
Stop Net: [See "Beach Seine", above] A term used for large mesh nets that are set out of "run" perpendicular to the beach. Stop nets are not intended to catch anything themselves, given that the mesh size in these nets is from six (6) to ten (10) inches. During the night, migrating mullet (or other fishes) gather against the stop net, which they perceive as an obstruction to travel. Other species may either swim through the stop net or go around it. A beach seine is used to gather the fish "encamped" at the stop net site. A recent DMF study showed that ninety-five percent (95%) of the fish "encamped" at the stop net are mullet.	Use of this gear can seriously damage live rock formations. Recommend the continued prohibition of use in inside (internal) coastal waters. Federal rules should address the use of flynets in the EEZ.
Trammel Net: A multi-walled net usually made with two outer walls of large mesh (6" to 12" stretch or more" made of heavy gauge monofilament, and an inner wall of small mesh monofilament. A fish "pockets" itself between the walls.	Only impact is from lost or discarded nets. Recommend that better, more positive identification of net owner be required.
Trolling Gear: Fishing lines attached to a reel or directly to a boat and "trolled" through the water. Used when fishing for king mackerel, tuna, etc.	No known habitat impacts. No recommendations at this time.
Trot Line: Lines used in estuarine waters to catch crabs and fish, consisting of a long multi- or monofilament line baited at intervals, with or without hooks, used much like an ocean long-line.	No known habitat impacts. No recommendations at this time.

Appendix M: Research Options

(Currently under development)

Saltwater Fishing License

Prepared for the November 18, 2004 joint meeting of the Joint Legislative Commission on Seafood and Aquaculture and the Environmental Review Commission by Jeff Hudson, Commission Counsel.

General provisions governing Saltwater Fishing Licenses

License Requirement. It is unlawful for an individual to engage in recreational fishing in coastal fishing waters without having purchased a Saltwater Fishing License (SFL).

Exemption. An individual may engage in recreational fishing by means of recreational gear without holding a SFL if the individual is 18 years of age or younger and is currently enrolled in school and is making progress toward obtaining a high school diploma or its equivalent. **Note:** Holders of a Lifetime Resident Comprehensive Fishing License or a Lifetime Sportsman License are not exempt from the Saltwater Fishing License requirements.

Sale of Fish. An SFL does not authorize the license holder to sell fish taken under the license.

Purchase and Renewal. Any SFL may be purchased or renewed at designated offices of the Division of Marine Fisheries (Division); from the Division by mail, electronic mail, the internet, or telephone; or at locations designated by the Board of Trustees of the North Carolina Saltwater Fishing Fund.

Types of Saltwater Fishing Licenses

License Type	Fee	Duration
1-year SFL	$15.00	Valid for a period of one year from the date of issuance
2-year SFL	$30.00	Valid for a period of two years from the date of issuance
3-year SFL	$45.00	Valid for a period of three years from the date of issuance
7-day SFL	$1.00	7 day duration, but may only be purchased once per year
Subsistence SFL	No charge	Valid for a period of one year from the date of issuance
Lifetime SFL:		Lifetime duration
Younger than 6 years of age	$100.00	
6 to younger than 11 years of age	$150.00	
11 to younger than 18 years of age	$200.00	
18 years of age and older	$500.00	

North Carolina Saltwater Fishing Fund

The North Carolina Saltwater Fishing Fund (Fund) is established as a nonreverting fund in the office of the State Treasurer to receive license revenues. The State Treasurer will invest the assets of the Fund and disburse investment income only as directed by the Board of Trustees of the Fund (Board). State agencies, local governments, and nonprofit corporations whose primary purpose is conserving, preserving, or restoring the State's marine resources are eligible to apply for a grant from the Fund.

North Carolina Saltwater Fishing Fund (continued)

The Board may authorize disbursement for:

- Resource and habitat enhancement.
- Fisheries management research for specifically designated species.
- Acquisition of land that provides for the enhancement of fishery habitat or public access to coastal fishing waters.
- Purchase or construction of public beach access areas and public marinas. If the Board purchases or constructs a public marina, it may establish a boat docking fee.
- Emergency dredging for the restoration of access to public fishing areas.
- Establishment of scholarships for individuals pursuing degrees in marine sciences.
- Administrative and operating expenses of the Board (no more than 2% of the annual Fund balance or $1,250,000, whichever is greater, may be used).

The Board may not authorize disbursement for law enforcement. The Board will be composed of eleven members as follows:

- Three members, each of whom holds a saltwater fishing license (SFL), to be appointed by the Governor.
- Three members, each of whom holds a SFL, to be appointed by the Speaker of the House of Representatives.
- Three members, each of whom holds a SFL, to be appointed by the President Pro Tempore of the Senate.
- The Director of the Division or the Director's designee (*ex officio* and non-voting).
- The Chair of the Marine Fisheries Commission (MFC) or the Chair's designee (*ex officio* and non-voting).

The Chair of the Board will report to the Joint Legislative Commission on Seafood and Aquaculture by September 30 of each year on the source and amounts of monies credited to the Fund and the purpose and amount of all expenditures from the Fund during the prior fiscal year.

Miscellaneous Provisions

- The MFC shall adopt rules to define recreational gear and commercial gear.
- The MFC and the Division may not disclose personal information provided by a license applicant.
- The Board shall develop a plan for the implementation of the licensing provisions of the act and study the creation of a unified fishing license for inland and coastal fishing. The Board will report to the Joint Legislative Commission on Seafood and Aquaculture on the plan and study no later than April 15, 2005.
- Of the funds appropriated to Department of Environment and Natural Resources for the 2004-2005 fiscal year, the Division may use up to $450,000 and the Board may use up to $300,000 to implement the saltwater fishing license program. The Board shall repay all of these funds to the General Fund by July 1, 2008.

Effective Date

The licensing provisions become effective January 1, 2006. All other provisions of this act became effective August 17, 2004.

GENERAL ASSEMBLY OF NORTH CAROLINA
SESSION 2003

SESSION LAW 2004-187
HOUSE BILL 831

AN ACT TO ESTABLISH THE NORTH CAROLINA SALTWATER FISHING FUND AND LICENSE AND TO PROVIDE THAT VACANCIES MAY BE FILLED IN CERTAIN OFFICES DURING A HOLDOVER PERIOD.

Whereas, the State of North Carolina has one of the most diverse fisheries in the United States; and

Whereas, the General Assembly recognizes that for many citizens fishing is an important recreational activity and that saltwater fishing is a source of great personal enjoyment and satisfaction; and

Whereas, the General Assembly recognizes the importance of providing plentiful fishery resources to maintain and enhance tourism as a major contributor to the economy of the State; and

Whereas, the General Assembly recognizes that commercial fishermen perform an essential function by providing wholesome food for the citizens of the State, nation, and world, and thereby properly earn a livelihood; and

Whereas, the General Assembly recognizes the economic contribution and important heritage of traditional full-time and part-time commercial fishing; and

Whereas, the General Assembly recognizes the need to protect our coastal fishery resources and to balance the commercial and recreational interests through better management of these resources; and

Whereas, the General Assembly is committed to the continued viability of both recreational and commercial fishing industries in the State; and

Whereas, the General Assembly intends that the commercial fishing industry be allowed to continue to take fish by means of all methods traditionally employed in commercial fishing operations, including the use of nets and trawls, subject to federal and State law and rules adopted by the Marine Fisheries Commission pursuant to G.S. 143B-289.52; and

Whereas, the General Assembly finds that in order to protect coastal fishery resources, it is essential that the recreational as well as the commercial fishing sectors provide data on use of fishery resources for the development of scientifically valid plans to manage fishery resources; and

Whereas, the General Assembly finds that it is essential to the success of efforts to better manage fishery resources that both the recreational and commercial fishing sectors are involved in and support these efforts; Now, therefore,

The General Assembly of North Carolina enacts:

SECTION 1. Chapter 113 of the General Statutes is amended by adding a new Article to read:

"Article 14C.
"North Carolina Saltwater Fishing Fund.

"**§ 113-175. Definitions.**

As used in this Article:

(1) 'Board of Trustees' means the Board of Trustees of the Fund.

(2) 'Fund' means the North Carolina Saltwater Fishing Fund.

(3) 'Investment income' means interest earned from the investment of license revenues and the proceeds of any gifts, grants, or contributions deposited in the Fund.

(4) 'License revenues' means the net proceeds from the sale of Saltwater Fishing Licenses issued under G.S. 113-174.2. The term includes funds realized from the sale, lease, rental, or other grant of rights to real or personal property acquired or produced with license revenues and federal aid project reimbursements to the extent that license revenues originally funded the project for which the reimbursement is made.

"**§ 113-175.1. North Carolina Saltwater Fishing Fund.**

There is hereby established the North Carolina Saltwater Fishing Fund as a nonreverting fund in the office of the State Treasurer. The purpose of the Fund is to enhance the fishery resources of the State for commercial and recreational fishing. License revenues and the proceeds of any gifts, grants, and contributions to the State that are specifically designated for inclusion in the Fund shall be deposited in the Fund. The State Treasurer shall hold the Fund separate and apart from all other moneys, funds, and accounts. The State Treasurer shall invest the assets of the Fund in accordance with the provisions of G.S. 147-69.2 and G.S. 147-69.3.

"**§ 113-175.2. Board of Trustees of the North Carolina Saltwater Fishing Fund.**

(a) Board of Trustees Established. – There is hereby established the Board of Trustees of the North Carolina Saltwater Fishing Fund. The Board of Trustees shall be independent, but for administrative purposes shall be located under the Department of Environment and Natural Resources.

(b) Membership; Qualifications. – The Board of Trustees shall consist of 11 members as follows:

(1) One individual appointed by the Governor, who has purchased a current Saltwater Fishing License at the time of the appointment.

(2) One individual appointed by the Governor, who has purchased a current Saltwater Fishing License at the time of the appointment.

(3) One individual appointed by the Governor, who has purchased a current Saltwater Fishing License at the time of the appointment.

(4) One individual appointed by the General Assembly upon the recommendation of the Speaker of the House of Representatives in accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(5) One individual appointed by the General Assembly upon the recommendation of the Speaker of the House of Representatives in accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(6) One individual appointed by the General Assembly upon the recommendation of the Speaker of the House of Representatives in accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(7) One individual appointed by the General Assembly upon the recommendation of the President Pro Tempore of the Senate in accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(8) One individual appointed by the General Assembly upon the recommendation of the President Pro Tempore of the Senate in accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(9) One individual appointed by the General Assembly upon the recommendation of the President Pro Tempore of the Senate in

accordance with G.S. 120-121, who has purchased a current Saltwater Fishing License at the time of appointment.

(10) The Director of the Division of Marine Fisheries or the Director's designee shall serve as a nonvoting, ex officio member of the Board of Trustees.

(11) The Chair of the Marine Fisheries Commission, or the Chair's designee shall serve as a nonvoting, ex officio member of the Board of Trustees.

(c) Officers. – The Governor shall appoint a member of the Board of Trustees to serve as Chair. The Chair shall serve at the pleasure of the Governor. The Board of Trustees shall elect one of its members to serve as Vice-Chair. The Vice-Chair shall serve a one-year term beginning July 1 and ending June 30 of the following year. The Vice-Chair may serve any number of consecutive terms.

(d) Terms. – The term of office of members of the Board of Trustees appointed under subdivisions (1) through (9) of subsection (b) of this section is three years. A member appointed under subdivisions (1) through (9) of subsection (b) of this section may be reappointed to any number of successive three-year terms. Upon the expiration of a three-year term, a member shall continue to serve until a successor is appointed and duly qualified as provided by G.S. 128-7. The term of members appointed under subdivisions (1), (4), and (7) of subsection (b) of this section shall expire on June 30 of years evenly divisible by three. The term of members appointed under subdivisions (2), (5), and (8) of subsection (b) of this section shall expire on June 30 of years that precede by one year those years that are evenly divisible by three. The term of members appointed under subdivisions (3), (6), and (9) of subsection (b) of this section shall expire on June 30 of years that follow by one year those years that are evenly divisible by three. An individual appointed under subdivisions (1) through (9) of subsection (b) of this section must continue to have a current Saltwater Fishing License in order to remain eligible to serve on the Board of Trustees.

(e) Vacancies. – An appointment to fill a vacancy shall be for the unexpired balance of the term. If a vacancy occurs for a member subject to appointment by the General Assembly upon the recommendation of the Speaker of the House of Representatives or the President Pro Tempore of the Senate, the vacancy shall be filled in accordance with G.S. 120-122.

(f) Meetings; Frequency. – The Board of Trustees shall meet at least twice each year and may hold special meetings at the call of the Chair or a majority of the members. Six members of the Board of Trustees shall constitute a quorum for the transaction of business.

(g) Per Diem and Expenses. – The Trustees shall receive per diem and necessary travel and subsistence expenses in accordance with the provisions of G.S. 138-5. Per diem, travel, and subsistence expenses shall be paid from the Fund.

"**§ 113-175.3. Allocation of investment income of the Fund; other powers and duties.**

(a) Disbursement of Funds. – The State Treasurer shall disburse investment income only upon the written direction of the Board of Trustees.

(1) The Board of Trustees may authorize the disbursement of investment income that accrues to the Fund for:

a. Resource and habitat enhancement, including, but not limited to, creation of natural nursery areas, construction of artificial reefs, restoration and enhancement of submerged aquatic vegetation, creation and restoration of oyster habitat, and acquisition of land or an interest in land that provides for the preservation of critical fisheries habitat.

b. Grants to fund fisheries management research for specifically designated species.

c. Acquisition of land or an interest in land that provides for the enhancement of fishery habitat or public access to coastal fishing waters.

d. Purchase or construction of public beach access areas and public marinas. If the Board of Trustees purchases or constructs a public marina, it may establish a boat docking fee.

e. Emergency dredging for the restoration of access to public fishing areas.

f. Establishment of scholarships for individuals pursuing degrees in marine sciences.

g. Administrative and operating expenses of the Board of Trustees.

(2) The Board of Trustees shall not authorize the disbursement of investment income that accrues to the Fund for law enforcement purposes.

(b) Applicants. – Any of the following are eligible to apply for monies from the Fund:

(1) A State agency.

(2) A local government or other political subdivision of the State or a combination of such entities.

(3) A nonprofit corporation whose primary purpose is the conservation, preservation, or restoration of the marine resources of the State.

(c) Administrative and Operating Expenses. – No more than two percent (2%) of the annual balance of the Fund on July 1 or a total sum of one million two hundred fifty thousand dollars ($1,250,000), whichever is greater, may be used each fiscal year for administrative and operating expenses of the Board of Trustees.

(d) Acquisition of Real Property. – The Board of Trustees may acquire real property by purchase, negotiation, gift, or devise. Any acquisition of real property by the Board of Trustees must be reviewed and approved by the Council of State and the deed for the real property subject to approval of the Attorney General before the acquisition can become effective. Nothing in this section shall allow the Board of Trustees to acquire real property by eminent domain.

(e) Real Property Management. – The Board of Trustees may designate managers or managing agencies of the real property acquired under this Article.

(f) Designation of Locations for Purchase and Renewal of Licenses. – Pursuant to G.S. 113-174.2, the Board of Trustees may designate locations at which Saltwater Fishing Licenses may be purchased and renewed.

(g) The Board of Trustees may adopt rules to implement this Article.

"**§ 113-175.4. Report.**

The Chair of the Board of Trustees shall submit to the Joint Legislative Commission on Seafood and Aquaculture by September 30 of each year a report on the Fund that shall include the source and amounts of all moneys credited to the Fund and the purpose and amount of all expenditures from the Fund during the prior fiscal year."

SECTION 2. Chapter 113 of the General Statutes is amended by adding a new Article to read:

"Article 14B.

"Saltwater Fishing Licenses.

"**§ 113-174. Definitions.**

As used in this Article:

(1) 'Commission' means the Marine Fisheries Commission.

(2) 'SFL' means Saltwater Fishing License.

(3) 'Division' means the Division of Marine Fisheries in the Department of Environment and Natural Resources.

(4) 'North Carolina resident' means an individual who is a resident within the meaning of G.S. 113-130(4).

(5) 'Recreational fishing' means any activity preparatory to, during, or subsequent to the taking of any fish, the taking of which is subject to regulation by the Commission, by any means:

a. That does not constitute a commercial fishing operation as defined in G.S. 113-168.

b. Except as provided in G.S. 113-261.

"**§ 113-174.1. General provisions governing licenses.**

(a) License Purchase Required to Engage in Recreational Fishing. – It is unlawful for any individual to engage in recreational fishing in coastal fishing waters without having purchased a current license required by this Article. It is unlawful for any individual to engage in recreational fishing without complying with the provisions of this Article and rules adopted by the Commission under this Article.

(b) Sale of Fish Prohibited. – A license issued under this Article does not authorize an individual who takes or lands any species of fish under the authority of the Commission to sell, offer for sale, barter, or exchange the fish for anything of value. Except as provided in G.S. 113-168.4, it is unlawful for any individual who takes or lands any species of fish under the authority of the Commission by any means to sell, offer for sale, barter, or exchange these fish for anything of value.

(c) Assignment and Transfer Prohibited. – It is unlawful to buy, sell, lend, borrow, assign, or otherwise transfer a license issued under this Article or to attempt to buy, sell, lend, borrow, assign, or otherwise transfer a license issued under this Article.

(d) General Enforcement. – It is unlawful for any individual to engage in recreational fishing in coastal fishing waters in the State without providing the individual's name and residence address upon the request of an inspector or other law enforcement officer authorized to enforce federal or State laws, regulations, or rules relating to marine fisheries.

(e) Enforcement for Charterboats and Headboats. – An inspector or other law enforcement officer may only verify the licensure of an individual fishing from a charterboat or headboat after the charterboat or headboat has returned to shore and the individual has disembarked from the charterboat or headboat. Except as provided in G.S. 113-174.2(d), each individual on board a charterboat or headboat engaged in recreational fishing, other than crew members who do not engage in recreational fishing, must have purchased a current SFL issued pursuant to G.S. 113-174.2. An owner, operator, or crew member of a charterboat or headboat is not responsible for the licensure of a customer fishing from a charterboat or headboat.

(f) Cancellation. – The Division may cancel a license issued on the basis of false information supplied by the license applicant. A cancelled license is void from the date of issuance.

(g) Reporting Requirements. – A person licensed under this Article shall comply with the biological data sampling and survey programs of the Commission and the Division.

"**§ 113-174.2. Saltwater Fishing License.**

(a) License Required. – Except as otherwise provided in this Article, it is unlawful for any individual to engage in recreational fishing in coastal fishing waters by means of recreational gear without having purchased a current SFL issued under this section. It is unlawful for any individual fishing under a SFL to possess fish in excess of recreational possession limits.

(b) Purchase; Renewal. – Any license issued under this section may be purchased or renewed at designated offices of the Division; from the Division by mail, electronic mail, the Internet, or telephone; or at locations designated by the North Carolina Saltwater Fishing Fund Board of Trustees.

(c) Types of SFLs; Fees; Duration. – The Division shall issue the following SFLs:

(1) One-year SFL. – $15.00. This license is valid for a period of one year from the date of issuance.

(2) Two-year SFL. – $30.00. This license is valid for a period of two years from the date of issuance.

(3) Three-year SFL. – $45.00. This license is valid for a period of three years from the date of issuance.

(4) Seven-day SFL. – $1.00. This license is valid for a period of seven consecutive days. An individual may purchase this license only once in any 12-month period.

(5) Subsistence SFL. – An applicant for a license under this subdivision shall provide to the Division a certification from the Department of Health and Human Services that the individual falls below the federal poverty level. A license issued under this subdivision shall be issued without charge and is valid for a period of one year from the date of issuance.

(6) Lifetime SFL. – This license is valid for the lifetime of the licensee. The fee for the Lifetime SFL, based on the age of the prospective licensee as of the date on which the application is filed with the Division, is:

a.	Younger than six years of age	$100.00
b.	Six years of age to younger than 11 years of age	$150.00
c.	11 years of age to younger than 18 years of age	$200.00
d.	18 years of age or older	$500.00

(d) Exemptions. – An individual may engage in recreational fishing by means of recreational gear without having purchased a SFL if the individual is 18 years of age or younger and is currently enrolled in school and is making progress toward obtaining a high school diploma or its equivalent."

SECTION 3. G.S. 113-169.2 reads as rewritten:

"**§ 113-169.2. Shellfish license for North Carolina residents without a SCFL.**

(a) ~~License or Endorsement Necessary to Take or Sell Shellfish.~~ Requirement. – It is unlawful for an individual to take shellfish from the public or private grounds of the State ~~by mechanical means or in quantities greater than the personal use limits set forth in subsection (i) of this section by any means~~ as part of a commercial fishing operation without holding either a shellfish license or a shellfish endorsement of a SCFL. A North Carolina resident who seeks only to take and sell shellfish shall be eligible to obtain a shellfish license without holding a SCFL. The shellfish license authorizes the licensee to sell shellfish.

(b) Repealed by Session Laws 1998-225, s. 4.17.

(c) Fees. – Shellfish licenses shall be issued annually upon payment of a fee of twenty-five dollars ($25.00) upon proof that the license applicant is a North Carolina resident.

~~(d) License Available for Inspection. It is unlawful for any individual to take shellfish in quantities greater than the personal use limits set forth in subsection (i) of this section from the public or private grounds of the State without having ready at hand for inspection a current and valid shellfish license issued to the licensee personally and bearing the licensee's correct name and address. It is unlawful for any individual taking or possessing freshly taken shellfish to refuse to exhibit the individual's license upon the request of an officer authorized to enforce the fishing laws.~~

(e) Repealed by Session Laws 1998-225, s. 4.17.

(f) Name or Address Change. – In the event of a change in name or address or upon receipt of an erroneous shellfish license, the licensee shall, within 30 days, apply for a replacement shellfish license bearing the correct name and address. Upon a showing by the individual that the name or address change occurred within the past 30 days, the trial court or

prosecutor shall dismiss any charges brought pursuant to this subsection.

(g) Transfer Prohibited. – It is unlawful for an individual issued a shellfish license to transfer or offer to transfer the license, either temporarily or permanently, to another. It is unlawful for an individual to secure or attempt to secure a shellfish license from a source not authorized by the Commission.

(h) Exemption. – Persons under 16 years of age are exempt from the license requirements of this section if accompanied by a parent, grandparent, or guardian who is in compliance with the requirements of this section or if in possession of a parent's, ~~grandparent's~~ grandparent's, or guardian's shellfish ~~license.~~license or a parent's, grandparent's, or guardian's shellfish endorsement of a SCFL.

~~(i) Taking Shellfish Without a License for Personal Use. –~~

~~(1) A person may take shellfish for personal use without obtaining a license under this section in quantities up to:~~

~~a. One bushel of oysters per day.~~
~~b. One half bushel of scallops per day.~~
~~c. One hundred clams per day.~~
~~d. Ten conchs per day.~~
~~e. One hundred mussels per day.~~

~~(2) Two or more persons who are using a vessel to take shellfish may take shellfish for personal use without obtaining a license under this section in quantities up to:~~

~~a. Two bushels of oysters per day.~~
~~b. One bushel of scallops per day.~~
~~c. Two hundred clams per day.~~
~~d. Twenty conchs per day.~~
~~e. Two hundred mussels per day.~~"

SECTION 4. G.S. 113-173(j)(4) is repealed.

SECTION 5. G.S. 120-122 reads as rewritten:

"**§ 120-122. Vacancies in legislative appointments.**

When a vacancy ~~occurs, other than by the expiration of term,~~ occurs in any office subject to appointment by the General Assembly upon the recommendation of the Speaker of the House of Representatives, upon the recommendation of the President Pro Tempore of the Senate, or upon the recommendation of the President of the Senate, and the vacancy occurs either: (i) after election of the General Assembly but before convening of the regular session; (ii) when the General Assembly has adjourned to a date certain, which date is more than 20 days after the date of adjournment; ~~or~~ (iii) after sine die adjournment of the regular ~~session,~~ session; or (iv) when the term of office expires and a successor has not been appointed, then the Governor may appoint a person to serve until the expiration of the term or until the General Assembly fills the vacancy, whichever occurs first. The General Assembly may fill the vacancy in accordance with G.S. 120-121 during a regular or extra session. When a person is holding over in office after the expiration of the term, for the purpose of this section that office may be filled as if it were vacant. Before making an appointment, the Governor shall consult the officer who recommended the original appointment to the General Assembly (the Speaker of the House of Representatives, the President Pro Tempore of the Senate, or the President of the Senate), and ask for a written recommendation. After receiving the written recommendation, the Governor must within 30 days either appoint the person recommended or inform the officer who made the recommendation that he is rejecting the recommendation. Failure to act within 30 days as required under the provisions of the preceding sentence shall be deemed to be approval of the candidate, and the candidate shall be eligible to enter the office in as full and ample extent as if the Governor had executed the appointment. The Governor shall not appoint a person other

than the person so recommended. Any position subject to initial appointment by the General Assembly but not filled prior to sine die adjournment of the Session at which the position was created or adjournment to a date certain which date is more than 20 days after the date of adjournment of the session at which the position was created may be filled by the Governor under this section as if it were a vacancy occurring after the General Assembly had made an appointment."

SECTION 6. G.S. 113-168(1) reads as rewritten:

"(1) 'Commercial fishing operation' means any activity preparatory to, during, or subsequent to the taking of any fish, the taking of which is subject to regulation by the Commission, either with the use of commercial fishing equipment or gear, or by any means if the purpose of the taking is to obtain fish for sale. Commercial fishing operation does not include (i) the taking of fish as part of a recreational fishing tournament, unless commercial fishing equipment or gear is ~~used or~~ used, (ii) the taking of fish under a ~~RCGL.~~ RCGL, or (iii) the taking of fish as provided in G.S. 113-261."

SECTION 7. G.S. 143B-289.52(a) is amended by adding a new subdivision to read:

"(13) To adopt rules to define fishing gear as either recreational gear or commercial gear."

SECTION 8. G.S. 143B-289.52 is amended by adding a new subsection to read:

"(h) Neither the Commission nor the Department may disclose personal information provided by an applicant for a license issued under Article 14A or 14B of Chapter 113 of the General Statutes."

SECTION 9. In order to establish a schedule of staggered terms of three years for the Board of Trustees of the North Carolina Saltwater Fishing Fund, the terms of members of the Board initially filling positions established by subdivisions (1), (4), and (7) of subsection (b) of G.S. 113-175.2, as enacted by Section 1 of this act, shall begin on the date the member is appointed and duly qualified and shall expire on June 30, 2010; the terms of members of the Board initially filling positions established by subdivisions (2), (5), and (8) of subsection (b) of G.S. 113-175.2, as enacted by Section 1 of this act, shall begin on the date the member is appointed and duly qualified and shall expire on June 30, 2009; the terms of members of the Commission initially filling positions established by subdivisions (3), (6), and (9) of subsection (b) of G.S. 113-175.2, as enacted by Section 1 of this act, shall begin on the date the member is appointed and duly qualified and shall expire on June 30, 2008.

SECTION 10. Notwithstanding G.S. 113-175.3, the Board of Trustees of the North Carolina Saltwater Fishing Fund may authorize disbursement and the State Treasurer may disburse up to fifty percent (50%) of the license revenues in the North Carolina Saltwater Fishing Fund during fiscal years 2005-2006 through 2015-2016.

SECTION 11. The first report required pursuant to G.S. 113-175.4, as enacted by Section 1 of this act, is due by September 30, 2005.

SECTION 12.(a) The Board of Trustees of the North Carolina Saltwater Fishing Fund shall develop a plan for the implementation of Section 2 of this act. The plan shall provide that:

(1) Licenses may be purchased or renewed via mail, electronic mail, the Internet, or telephone.

(2) The licensing and renewal system shall be fully automated and shall allow for the purchase or renewal of licenses at any time, without delay.

(3) The licensing system shall not require individuals to hold a physical license.

(4) Verification of licensure shall be accomplished by an individual providing only the individual's name and residence address.

SECTION 12.(b) The Board of Trustees of the North Carolina Saltwater Fishing Fund shall determine a date by which the plan developed pursuant to subsection (a) of this section would be fully implemented.

SECTION 12.(c) The Board of Trustees of the North Carolina Saltwater Fishing Fund shall study issues related to the establishment of a unified recreational fishing license for recreational fishing in both the inland and coastal fishing waters of the State. The Board shall make specific findings as to whether a unified licensing system should be adopted for recreational fishing in the State and, if so, what the system should be and how it should be implemented.

SECTION 12.(d) A report on the implementation plan, the determination of the date of full implementation, and the unified fishing license study required by subsections (a), (b), and (c) of this section shall be submitted to the Joint Legislative Commission on Seafood and Aquaculture no later than April 15, 2005.

SECTION 12.(e) Notwithstanding the provisions of G.S. 113-175.2 as enacted by Section 1 of this act, the requirement that members of the Board of Trustees of the North Carolina Saltwater Fishing Fund must have purchased a current Saltwater Fishing License at the time of appointment and the requirement that members of the Board of Trustees must continue to have a current Saltwater Fishing License in order to remain eligible to serve on the Board of Trustees shall not apply until such time as the Saltwater Fishing License becomes available.

SECTION 13. There is appropriated from the General Fund to the North Carolina Saltwater Fishing Fund for fiscal year 2004-2005 up to the sum of five million dollars ($5,000,000). Notwithstanding G.S. 113-175.3, as enacted by Section 1 of this act, the Board of Trustees of the North Carolina Saltwater Fishing Fund shall use these funds to implement the provisions of this act. Notwithstanding G.S. 113-175.3, as enacted by Section 1 of this act, the Board of Trustees shall repay funds appropriated pursuant to this section to the General Fund by July 1, 2010.

SECTION 14. If any section or provision of this act is declared unconstitutional or invalid by the courts, the unconstitutional or invalid section or provision does not affect the validity of this act as a whole or any part of this act other than the part declared to be unconstitutional or invalid.

SECTION 15. Sections 2, 3, and 4 of this act become effective January 1, 2006. All other sections of this act become effective when the act becomes law.

In the General Assembly read three times and ratified this the 17th day of July, 2004.

Comments on Saltwater Fishing License Presented to Joint Meeting of ERC and JLCSA

Division of Marine Fisheries

November 18, 2004

- **Immediate Tasks to be Completed**

  - ❑ The Board of Trustees (BOT) overseeing the license revenue fund is tasked with developing an implementation plan for license sales, determining a date for full implementation, and studying a unified recreational fishing license for both fresh and salt water fishing. A report on these tasks is to be submitted to the JLCSA no later than April 15, 2005.

    Status: The Board has not yet been appointed.

    The statute is mute on staff support for the BOT, but, DMF has assumed that role for the initial stages of plan development. Clarification of the source of staff support for the future will be necessary.

    DMF is moving ahead with identifying and evaluating options for license sales. Includes cost and benefit analysis of each option.

    They are: 1) Sales through a new system developed and managed by DMF, 2) Sales through an expanded WRC system, and 3) a unified license.

- **Public Comments on Legislation**

  - ❑ DMF developed a fact sheet and a list of frequently asked questions and posted them on the division's website (copies attached).

  - ❑ Comments through email and phone calls were recorded (summary attached).

    - Need blanket license for charter boats.
    - Lifetime WRC license should apply.
    - Two licenses needed if fishing in Joint Waters.

- **Recommendations and Concerns**

  - ❑ Potential Impacts to federal Sportfish Restoration Act (SRA) Funds

    - The annual grant is based on the size of the state and the number of licensed anglers in the state.

- NC receives approximately $5 million per year.
- DMF receives approximately $1.5 million of the state's grant. $3.5 million goes to the Wildlife Resources Commission.
- The SRA requires that a state is eligible for grants only if license revenues are not diverted from primary purpose of the agency.
- Assent legislation is necessary to assure that no such diversions occur.
- Preliminary review of the SFL by the US Fish and Wildlife Service indicates that certain eligible uses of funds would be considered a diversion (copy of opinion attached). They identified the funding category of scholarships and operating expenses of the board as diversions.
- Possible solutions include amendments to the statutes governing the authority of DMF, and changes to the SFL to restrict or redefine categories of activities that can be funded with license revenues.
- The Act also requires that the cost of processing the license not exceed the license fee in order for the license sales to count towards the level of grant eligibility for the state. This will be a problem with the $1, seven day license. The fee will need to be increased to solve this problem.

❑ Enforcement Issues

- SFL will increase demands on already limited enforcement capabilities.
- DMF has prepared and submitted to DENR an expansion budget request for more officers since funds from the SFL cannot be used for enforcement.
- Uncertainties about efficiency of available technology and how lack of efficiency will affect ability to manage a paperless license system.

❑ Funding Issues

- The SFL makes no provisions for funding either the staff or technology needs of the system to sell licences. Such needs are not identified as a category of funding that can be approved by the BOT. There are $450,000 available this year for developing the implementation plan, but, no assurances after that.

- The funding category for habitat enhancement should be expanded to allow funding of research and monitoring for traditional and innovative projects

❑ Licensing Issues

- Blanket permit for charter boats and piers.

  Results of DMF survey of For Hire Permit holders (copy attached)

  Could satisfy DMF management data needs

- Requirement to be pursuing a high school education will be impractical to verify and will cause enforcement problems. Match WRC exemption by lowering age from 18 to 16 with no education requirement.

- Increase duration of short term license to either 10 or 14 days and charge at least $5. Do not restrict how many can be bought in a year.

- The subsistence license qualifying criterion needs to be examined and simplified to something more specific than the "poverty level"; such as qualifying for either Medicaid, food stamps or housing assistance.

❑ Confidentiality of licensee information

- The SFL makes personal data on recreational and commercial license holders confidential. We have many examples of how the commercial data has been shared with others to the benefit of the fishermen. Confidentiality of that data will make similar use in the future impossible and should be removed.

- This problem could be corrected by allowing release of the data only to those that have signed a confidentiality statement to use the data for specific and pre-approved purposes.

❑ Unified license

- A good idea that will require careful analysis of all the costs and benefits.

❑ Effective date of license requirement

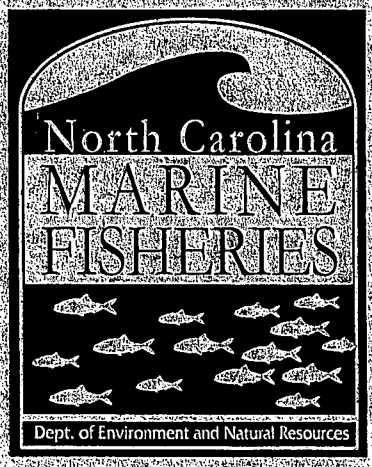
- The law specifies that the license requirements will be effective January 1, 2006. Development of the system cannot start until after the implementation plan is submitted to the JLCSA.

- The implementation plan is supposed to identify a date for full implementation of the license requirement. At this time, it is likely that the more realistic date is January 2, 2007.

North Carolina Saltwater Fishing License

License Types

- **Annual license for anyone age 18 or older, regardless of state residency - $15**
- **Seven-day license, regardless of state residency (can only be purchased once a year) - $1**
- **Subsistence license for fishermen whose annual income is below the federal poverty level – No Charge**
- **Lifetime license:** **Age 0 through Age 5 - $100**
  Age 6 through Age 10 - $150
  Age 11 through Age 17 - $200
  Age 18 and above - $500



Effective Date: Jan. 1, 2006

Requirements

The Saltwater Fishing License is an annual license allowing recreational fishermen to harvest seafood for personal consumption. The license is required for ***ANY*** type of recreational fishing activity not included under the N.C. Recreational Commercial Gear License. Seafood harvested under this license cannot be sold. Fishermen using this license will be held to the state's ***recreational size and possession limits***. This license cannot be assigned or transferred.

The license is required to recreationally fish in **Coastal Fishing Waters,** which include sounds, coastal rivers and their tributaries, out to three miles in the ocean. Recreational fishermen who catch fish in the **Exclusive Economic Zone** (3 miles – 200 miles offshore) will be required to possess this license to land fish in state waters. Fishing in **Joint Waters** (areas managed by both the Marine Fisheries and the Wildlife Resources commissions) will also require the Saltwater Fishing License.

Fishermen holding the Saltwater Fishing License are required to comply with all sampling and survey programs administered by the state Division of Marine Fisheries (DMF).

Individuals who hold a Wildlife Resources Commission Lifetime Fishing License are still required to purchase this license to recreationally fish in N.C.'s coastal and ocean waters.

Individuals 18 years and younger may fish without the license if they are currently enrolled in school and are making progress toward obtaining a high school diploma or its equivalent.

The license may be purchased or renewed at designated DMF offices; by mail, electronic mail, the Internet, or telephone; or at locations designated by the N.C. Saltwater Fishing Fund Board of Trustees. Upon request of a Marine Patrol officer, or other law enforcement officers authorized to enforce federal or state laws, regulations or rules relating to marine fisheries, the license holder must provide their name and residence address, but are not required to have the physical license in their possession.

N.C. Saltwater Fishing Fund

Proceeds from the sale of this license will go into the N.C. Saltwater Fishing Fund to be administered by an 11-member board of trustees. The board will issue grants to be used for resource and habitat enhancement, research, land acquisition to enhance fishery habitat or public access to coastal fishing waters, construction of public beach access and public marinas, emergency dredging to restore access to public fishing areas, marine science scholarships and administrative and operating expenses for the board. State and local agencies, and nonprofit organizations whose focus is conservation, preservation or restoration of marine resources, may apply for these grants.

For more information about the new Saltwater Fishing License, please visit www.ncdmf.net or call the DMF at 252-726-7021 or 1-800-682-2632 and ask for the License Office.

North Carolina's Saltwater Fishing License
Frequently Asked Questions

When will the Saltwater Fishing License be required?
The license is required beginning Jan. 1, 2006.

In what areas or waters will the license be required?
*The license is required to recreationally fish in **Coastal Fishing Waters**, which include sounds, coastal rivers and their tributaries, out to three miles in the ocean. Recreational fishermen who catch fish in the **Exclusive Economic Zone** (3 miles – 200 miles offshore) will be required to possess this license to land fish in state waters. Fishing in **Joint Waters** (areas managed by both the Marine Fisheries and the Wildlife Resources commissions) will also require the Saltwater Fishing License.*

Where can I purchase a license?
The license may be purchased or renewed at designated offices of the Division of Marine Fisheries (DMF); from the DMF by mail, electronic mail, the Internet, or telephone; or at locations designated by the North Carolina Saltwater Fishing Fund Board of Trustees.

How much will the license cost?
There are several different types of Saltwater Fishing License's available, each with different license durations and fees, see below:

*(1) **One-year license** - $15.00. This license is valid for a period of one year from the date of issuance.*

*(2) **Two-year license** - $30.00. This license is valid for a period of two years from the date of issuance.*

*(3) **Three-year license** - $45.00. This license is valid for a period of three years from the date of issuance.*

*(4) **Seven-day license** - $1.00. This license is valid for a period of seven consecutive days. An individual may purchase this license only once in any 12-month period.*

*~~(5) **Subsistence license.** - An applicant for a license under this subdivision shall provide to~~ the DMF a certification from the Department of Health and Human Services that the individual falls below the federal poverty level. A license issued under this subdivision shall be issued without charge and is valid for a period of one year from the date of issuance.*

*6) **Lifetime license** - This license is valid for the lifetime of the licensee. The fee for the Lifetime license, based on the age of the prospective licensee as of the date on which the application is filed with the DMF, is:*

a. Age 0 through Age 5 - $100
b. Age 6 through Age10 - $150
c. Age 11 through Age17 - $200
d. Age 18 and above - $500

I have a lifetime hunting and fishing license issued by the Wildlife Resources Commission; will this license cover me in coastal waters?
No, you will still need to purchase a Saltwater Fishing License.

Does everyone need a license or are there any exemptions?
There is only one exemption - an individual may engage in recreational fishing by means of recreational gear without having purchased a Saltwater Fishing License if the individual is 18 years of age or younger and is currently enrolled in school and is making progress toward obtaining a high school diploma or its equivalent.

Are licenses available for anglers who reside out of state?
Yes, they are available for everyone regardless of residency.

Are the license fees different for anglers who reside out of state?
No, they are the same.

Will I need a license to fish on a private or public pier?
Yes, in coastal waters no types of recreational fishing activities are exempt.

Will I need a license to fish on a charterboat or headboat?
Yes, in coastal waters no types of recreational fishing activities are exempt.

Will I need a license to fish from public or private shoreline?
Yes, in coastal waters no types of recreational fishing activities are exempt.

If I have a Saltwater Fishing License, can people fish on my private boat without purchasing a license?
No, they must all have a license if you are fishing in coastal waters.

Can I sell my catch if I have a Saltwater Fishing License?
No, seafood harvested under this license is for personal consumption and cannot be sold.

I have a standard commercial fishing license; do I still need a Saltwater Fishing License to go fishing for fun?
Yes.

Is the Saltwater Fishing License only required to fish with hook and line or do you need this license to use other recreational gears like gigs and castnets?
The license is required for ANY type of recreational fishing activity not included under the N.C. Recreational Commercial Gear License.

Which recreational gear use beside hook and line would require someone to purchase a Saltwater Fishing License?
Any type of recreational activity not included under the N.C. Recreational Commercial Gear License will require this license. This includes, but is not limited to spears, gigs, hook-and-line, bait-and-line, seines less than 30 feet, dip nets, landing nets, cast nets and recreational shellfish activities.

I have a Recreational Commercial Gear License (RCGL); do I still need a Saltwater Fishing License to go fishing for fun with a rod and reel?
Yes.

Do I need a Saltwater Fishing License and a RCGL to set my RCGL gear for recreational purposes?
No, only a RCGL is required to set RCGL gear.

Do I need a Saltwater Fishing License to catch shellfish recreationally?
Yes.

Which species of shellfish are included?
All types.

Do I need a Saltwater Fishing License to use a bait and line to catch crabs?
Yes.

How many crab pots can I set if I have a Saltwater Fishing License?
You may set one crab pot per Saltwater Fishing License holder. The pot has to be attached to the shore along privately owned land or to a privately owned pier and must have a buoy that is no less than five inches in diameter and no less than five inches in length. Engraved in the buoy or engraved in a metal or plastic tag attached to the buoy, must be the license holder's last name and initials and one of the following if vessel is used: owner's N.C. motor boat registration number (Wildlife Resources Commission number), or owner's U.S. vessel documentation name.

If I hold a Saltwater Fishing License can I keep all the fish and seafood I catch?
No, you will be held to the state's recreational size and possession limits.

Can I transfer my Saltwater Fishing License to a family member or other person if I'm not using it?
No, it is unlawful to buy, sell, lend, borrow, assign, or otherwise transfer a license to any other individual.

What kind of documentation do I need to prove I have a Saltwater Fishing License?
You must provide your name and residence address upon the request of a Marine Patrol officer or any other law enforcement officer authorized to enforce federal or state laws, regulations, or rules relating to marine fisheries. You do not have to have the license in your possession.

Are there any other Saltwater Fishing License requirements?
Yes, there are reporting requirements. A person licensed shall comply with the biological data sampling and survey programs of the DMF.

Where does all the Saltwater Fishing License money go?
A N.C. Saltwater Fishing Fund will be established as a nonreverting fund in the office of the state treasurer. License revenues and the proceeds of any gifts, grants, and contributions to the state specifically designated for inclusion in the N.C. Saltwater Fishing Fund shall be deposited in the fund. The state treasurer shall hold the fund separate and apart from all other moneys, funds, and accounts. The state treasurer shall invest the assets of the fund in accordance with the provisions of G.S. 147-69.2 and G.S. 147-69.3.

How will the Saltwater Fishing License money be spent?
The board of trustees may authorize the disbursement of 50 percent of the license revenues for the first ten years. After that, they may only spend the investment income that accrues from the fund.

The Fund may be used for:
a. Resource and habitat enhancement, including, but not limited to, creation of natural nursery areas, construction of artificial reefs, restoration and enhancement *of submerged aquatic vegetation, creation and restoration of oyster habitat, and acquisition of land or an interest in land that provides for the preservation of critical fisheries habitat.*

b. Grants to fund fisheries management research for specifically designated species.

c. Acquisition of land or an interest in land that provides for the enhancement of fishery habitat or public access to coastal fishing waters.

d. Purchase or construction of public beach access areas and public marinas. If the board of trustees purchases or constructs a public marina, it may establish a boat docking fee.

e. Emergency dredging for the restoration of access to public fishing areas.

f. Establishment of scholarships for individuals pursuing degrees in marine sciences.

g. Administrative and operating expenses of the board of trustees.

The board of trustees shall not authorize the disbursement of investment income that accrues to the fund for law enforcement purposes. The purpose of the fund is to enhance the fishery resources of the state for commercial and recreational fishing.

Who can apply for this money?
Any of the following are eligible to apply for monies from the fund:

(1) A state agency.
(2) A local government or other political subdivision of the state or a combination of such entities.
(3) A nonprofit corporation whose primary purpose is the conservation, preservation, or restoration of the marine resources of the state.

Who decides how the Saltwater Recreational Fund is used?
The North Carolina Saltwater Fishing Fund Board of Trustees.

How are the members of the North Carolina Saltwater Fishing Fund Board of Trustees appointed?
There will be 11 Members. The Marine Fisheries Director and Chairman of the Marine Fisheries Commission will be members along with three members appointed by the Governor, three members appointed by the Speaker of the House, and three members appointed by the Senate President ProTempore.

Will there be any additional modifications to the Saltwater Fishing License requirements prior to its implementation?
Possibly. Several members of the General Assembly expressed an interest in revisiting the license issue during the next legislative session.

Summary of Public Input/Interest in the North Carolina Saltwater Fishing License

Prepared by the N.C. Division of Marine Fisheries

During the last legislative session, consideration of the new Saltwater Fishing License received a great deal of media attention and fishermen began contacting the Division of Marine Fisheries to share their views and concerns about the potential new license. While the bill was being debated, the majority of the calls and inquiries centered on the issue of a blanket license for charter boats – many charter and headboat operators felt they needed to have a blanket license in order to effectively run their businesses.

Upon passage of the Saltwater Fishing License, the Division of Marine Fisheries developed a fact sheet containing the major points of the legislation and posted it on-line in response to the demand from the public for information about the new license. The fact sheet has been well received – to date the page has had 9,851 visitors.

Since passage of the new license, the vast majority of the calls and correspondence have focused on the question of an exemption for those individuals who have purchased a lifetime comprehensive fishing license issued by the N.C. Wildlife Resources Commission. These fishermen feel strongly that they bought a lifetime license with the understanding that their hunting and fishing requirements would be covered for the rest of their life. They now feel betrayed that the state is requiring them to buy another license to fish in coastal waters.

The next most frequently mentioned topic concerns license requirements for Joint Waters, which are waters managed by both the Marine Fisheries and the Wildlife Resources commissions. As the law is currently interpreted, fishermen will need to hold both a Freshwater License and the new Saltwater Fishing License to fish in Joint Waters. Fishermen feel this is an unfair burden and that either license should cover them in Joint Waters.

Other comments have been:

- The $500 Lifetime License is too expensive and should be the same cost as the WRC Lifetime Fishing License ($250).
- The $15 annual fee is too much.
- The $1 per week license is too little.
- The $1 license should be good for two weeks.
- Create a combined North Carolina Fishing License for both fresh and saltwater to simplify the licensing process.
- Tourism will be adversely impacted by the new license.
- A portion of revenues generated by the new license should be allocated for additional law enforcement.
- An exemption needs to be created for the disabled.
- There is no need for the license.

Memorandum

To: Regional Solicitor, DOI, Atlanta, GA

From: Acting Regional Director, Southeast Region /s/ Cynthia K. Dohner

Subject: Request for Solicitor's opinion on North Carolina Saltwater Sport fish fishing license

The General Assembly of North Carolina in session 2003 passed legislation (Session Law 2004-187) establishing a Saltwater Fishing Fund to be supported, in part, by a fishing license for saltwater sport fish (Attachment 1). The license is effective January 1, 2006, and will be administered by the Division of Marine Fisheries. Prior to this legislation the State of North Carolina has not required a fishing license for saltwater sport fishing. Both the Sport Fish Restoration Act and our program regulations found in 50 CFR 80 establish criteria that must be met before a State is eligible to participate in the Sport Fish Restoration program. We have reviewed the legislation and have identified six issues on which we would like your opinion. Five issues pertain to the potential diversion of license revenues, and the sixth issue is related to assent legislation. For your reference, a copy of North Carolina General Statutes Chapter 113, Conservation and Development, is provided as Attachment 2.

A diversion of license revenue occurs when fees paid by hunters and fishermen are used for purposes other than the administration of the State fish and wildlife agency. The administrative function and legislative duties and powers of the Division of Marine Fisheries are identified and located in North Carolina General Statutes Chapter 113, Conservation and Development, Article 15, § 113-181 (Attachment 2). Federal regulations in 50 CFR 80.4 stipulate that "Revenues from license fees paid by hunters and fishermen shall not be diverted to purposes other than administration of the State fish and wildlife agency." Subsection (b) further states "... administration of the State fish and wildlife agency include only those functions required to manage the fish and wildlife-oriented resources of the State for which the agency has authority under State law." Regulations in 50 CFR 80.4 (c) states, "A diversion of license fee revenues occurs when any portion of license revenues is used for any purpose other than the administration of the State fish and wildlife agency."

The current legislation in § 113-175.2(a) establishes a Board of Trustees of the North Carolina Saltwater Fishing Fund. The Board of Trustees shall be independent, but for administrative purposes shall be located under the Department of Environment and Natural Resources. The Board of Trustees will serve to authorize approval and disbursement of investment income from

the Salt Water Fishing Fund for seven specific purposes identified in the legislation at § 113-175.3. Administrative and operating expenses paid to the Board of Trustees for per diem, expenses, travel, etc., will be from the Salt Water Fishing Fund and will not exceed two percent of the balance of the fund on July 1 or $1,250,000 whichever is greater. The following are our specific concerns requiring the Regional Solicitors review and opinion :

Is the operation of the Board of Trustees an authorized administrative function of the Department of Environment and Natural Resources based on legislation at § 113-181?

Are the costs paid to the Board of Trustees for expenses a diversion of license revenues?

Are the seven activities The Board of Trustees has authority to disburse investment income from the Salt Water Fishing Fund authorized pursuant to legislation at § 113-181?

Based on the Organization Chart Attachment 3 and individual assent legislation found in North Carolina General Statutes Chapter 113, Conservation and Development, § 113-181 Division Marine Fisheries and § 113-307.1 Wildlife Resources Commission, we would like an opinion if the Division of Marine Fisheries and Wildlife Resources Commission are separate agencies for the purposes of diversion determination.

If it is determined that the North Carolina Division of Marine Fisheries Commission has created a diversion of funds would this impact the freshwater fisheries program of the North Carolina Wildlife Resources Commission.

Pursuant to 50 CFR 80.3 a State may participate in the benefits of the Sportfish Restoration Act only after it has passed legislation which assents to the provisions of the Acts and has passed laws for the conservation of the fish and wildlife including a prohibition against the diversion of license fees paid by hunters and sport fishermen to purposes other than administration of the fish and wildlife agency. A review of the legislation found in North Carolina General Statutes Chapter 113, Conservation and Development, § 113-181 Division of Marine Fisheries and § 113-307.1 Wildlife Resources Commission confirms each agency has individual assent legislation. However, legislation found at § 113-181 does not include a prohibition against the diversion of license fees paid by sports fisherman. Until this time a license for saltwater sport fishing has not been required in North Carolina. Our specific concern requiring the Regional Solicitors review and opinion regarding assent legislation follows:

Does the Legislature need to enact separate assent legislation for the Saltwater Fishing Fund, or is the existing assent legislation at § 113-307.1 adequate?

If you should have any questions, please contact me at 404/679-4000 or Mr. Michael L. Piccirilli at 404/679-4154.

Statement to the Joint Legislative Commission on Seafood and Aquaculture and the Environmental Review Commission on

Implementation of the Salt Water Fishing License (Article 14C, Chapter 113, NCGS) and Its Impact on the Wildlife Resources Commission by

Richard B. Hamilton, Executive Director, NCWRC
November 18, 2004

The concept of licensing fishers and hunters is well established and sound. License fees support regulatory, enforcement, research, management, and education programs of most state fish and wildlife agencies. License information provides a valuable database from which fish and wildlife managers can estimate important population and harvest information that is used to regulate and protect the resource. License fees and information from licensees have served the programs of the WRC well over the past sixty years. Licensing fishers in coastal waters is a sound and positive development that will yield important returns to our coastal resources and to the people who enjoy them.

WRC has many resources and capabilities that could enable a relatively smooth, efficient, and equitable transition and implementation of the new salt water fishing license requirement. Correct implementation of the salt water fishing license, building on the years of experience and capability of the WRC will save the State millions of dollars and considerable time in implementing this new license. The constituency of the WRC is expressing concern over the impact the new license may have upon them and their fishing activities. We have received hundreds of inquiries through our 1200 license agents, over our webpage, and directly by telephone and mail since the new license requirement was enacted this summer. These people are not against the license, but they have questions and concerns that must be addressed.

I will list the major concerns we have identified and the ones we are hearing over the probable impact the salt water fishing license will have on programs of the WRC and its licensed fishers. I will also give possible solutions to these problems to be considered as the Board of Trustees and General Assembly implements and improves the new license as provided by ratified HB 831.

- Protection of Sport Fish Restoration Funds – North Carolina receives over $5 million annually from Sport Fish Restoration Grants

administered through the USFWS. A condition of eligibility for a state to participate in this federal grant program is passage of "Assent Legislation" by the state stating that license fees will be used exclusively for administration of the fishery program and for no other purpose. Such legislation exists to protect inland fishing license revenues from diversion, but was not included in the salt water fishing license. Failure to pass this assurance jeopardizes the entire federal grant program for NC and would cause us to lose the entire $5 million every year.

- Uses of the Fund – Federal officials have reviewed ratified HB 831 and told us that they will consider NC to be in non-compliance with diversion of license fees under the new license unless some of the allowable uses are eliminated or changed. Specifically, the uses in question are dredging for boat access to fishing areas and scholarship awards. They also raised a question about the allowance of $1,250,000 per year for administration and operation of the Board of Trustees. These issues need to be addressed and agreement reached with USFWS to insure that Sport Fish Restoration Grants for NC are not lost.
- Unified Fishing License – The law directs the Board to consider the feasibility and benefits of developing a unified fishing license. WRC believes that a unified fishing license is the most equitable and practical approach to implementation of the salt water fishing license. A unified fishing license will eliminate the unnecessary burden placed upon fishers by requiring separate licenses depending upon the classification of water where they fish. The concept of a unified license can easily be implemented by creating a salt water fishing license ($15) that can be used in coastal and joint waters and by selling a privilege supplement ($5) for the regular inland fish license ($15) that will allow fishing in inland, joint, and coastal waters. Fees from the salt water license and from the supplement to the inland waters license would go to the new Salt Water Fishing Fund.
- License Structure – The license structure of the salt water fishing license should be simple for ready understanding by the public and for economy in implementation. There should be an annual license (12 months) for $15, a week license (7days) for $10, and a daily license for $5. Eliminate the two year and three year licenses because they are cumbersome and unnecessary. Inland fishing licenses should follow the same structure and fee. The structure outlined here is simple and functional and provides great flexibility to the fisher. All the fees, durations, exemptions, age limits and categories for fishing licenses should be consistent between salt water and inland water fishing licenses. For instance, the salt water

license gives an exemption for persons under 18 while the age exemption for the inland water license is 16. This is unnecessarily confusing. The categories and fees for lifetime licenses are different for salt water and inland water licenses. No reason for these differences is clear. The $1 license for 7 days should be eliminated because it costs more than $1 to issue and record a license and rules apportioning federal funds among the states do not allow counting licenses that generate no positive income for program support.

- The "subsistence fishing license" established by ratified HB 831 is a fine idea and should be applied to inland fishing as well. This change will eliminate the huge natural bait exemption in inland waters except for persons who are below the poverty level in income and who justifiably need exemption from license fees. The provision in the new salt water fishing license that protects license holders from release of private information collected when they buy a license is good and should be applied to all hunting and fishing licenses too.
- Lifetime Licenses – The greatest concern we have heard (and it has been loud and clear) is from our current lifetime license holders who insist that their lifetime license came with a promise from the State that this is the only hunting or fishing license that would ever be needed to hunt or fish in NC. We recommend that current lifetime license holders be grandfathered into the lifetime salt water license at no cost. After implementation of the unified fishing license concept, a lifetime salt water fishing license for adults could be sold ($250) with the revenue going to the salt water endowment fund. A lifetime inland fishing license for adults would be sold ($250) with an optional salt water rider for $50 which would allow fishing in salt water. The $50 fee would be deposited into the salt water endowment fund. An infant and youth lifetime salt water fishing license could also be sold at reduced prices, but the adult license should be sold for the same fee as the lifetime inland water fishing license ($250) and the age categories for both types of licenses should be the same.
- Sale of Licenses – The current law provides for sale of salt water fishing licenses through outlets authorized by the Board of Trustees. The most efficient and cost effective way to sell these new licenses is through the WRC system. This system already exists, it is known to fishers, and it is efficient and robust. We can add the new salt water fishing license in its simplified and unified form, sell 1 million of them every year, keep the records that will be accessible to DMF for research and management purposes, and transfer the revenue to the salt water fishing fund every week within a reasonable cost

and timeframe. We figure it will cost about $500,000 to add 100 agents in coastal areas, to acquire additional computer and server capacity for 1 million licenses, and to write programs for reports and updates to DMF. We can do this work in house within six months. The law should be changed to direct that sales be handled through the existing WRC system of agents and other sales media. The law should also be changed to eliminate sales by e-mail because this method is not secure and is not an acceptable business practice. All other sales media are feasible and WRC is already selling licenses in these ways.

- Effective Date – The effective date for implementation of the new salt water fishing license should be changed to July 1, 2006 to allow adequate time to establish a unified fishing license, to establish the system for distribution and accounting, and to allow time for public awareness and understanding. This day is also the beginning of a new fiscal year which has some budget and administrative advantages.

These are fairly general observations and recommendations. We are available to work on these proposals to improve the salt water fishing license and to help with implementation as may be required to make this license meaningful and successful.

We will be conducting public hearings in January to present proposed changes to the hunting and inland fishing regulations for next year. We expect thousands of sportsmen and sportswomen to attend these hearings. Many of them will have questions and comments about the salt water fishing license. If you think it would be a good idea, we could focus on this issue and report back on the nature of comments we receive. We invite any Members who might be able to attend a hearing near you to join us to get input from our public. If Preston Pate or any legislative staff would like to attend these hearings to hear comments about the salt water fishing license, they are welcome.

Thank you for this opportunity to share some of our observations with you.

Comments on Saltwater Fishing License Presented to Joint Meeting of ERC and JLCSA

Daniel Whittle
On behalf of Environmental Defense and CCA North Carolina

November 18, 2004

- Thank you. I am speaking today on behalf of my organization, Environmental Defense and its more than 10,000 members in North Carolina, and on behalf of the NC Chapter of the Coastal Conservation Association (CCA), and its 5,000 members. Our two organizations have worked together for several years to support a saltwater fishing license for NC and wish to thank all of you for passing this important legislation.

- Most recently our two groups have worked with the NC Division of Marine Fisheries in identifying important next steps.

- The Saltwater Fishing Fund and License completes work began in 1997, when the General Assembly adopted the Fisheries Reform Act to prevent overfishing and to protect fish habitat.

- The license will provide resource managers with the data they need to manage fish stocks responsibly and sustainably. The Fund will provide millions of dollars to protect fish habitat, restore fish stocks, and fund research. This Act follows on the precedent established by the successful freshwater fishing license administered by the NC Wildlife Resources Commission. Time and time again, fishermen express support for license programs where revenues generated go directly back to the resource.

- NC also joins states from coastal states from Maryland to Texas, all of which have successful saltwater fishing license programs.

- Now the hard work begins. Getting the license program up and running will take time and money and your continued support. As Preston Pate indicated, it may also require a handful of technical amendments to the legislation to ensure that the program is efficient, cost-effective and fair.

- **Environmental Defense and CCA offer the following principles and recommendations for moving forward:**

Principles

- **Principle #1—Everyone who fishes should be counted.** This is the only way to ensure that data accurately captures fishing effort. In the few exceptions where some persons are exempt from obtaining a license (e.g., juveniles), alternative mechanisms should be used to estimate the number of those anglers.

- **Principle #2—The Division of Marine Fisheries should have adequate funding to administer and enforce the license program.**

- **Principle #3—Conservation funds should be dedicated to restoring and protect fish stocks and their habitats.**

Recommendations

- **Recommendation #1**—As soon as possible, the Governor, the Speaker of the House and the President Pro Tem of the Senate should make their appointments to the Board of Trustees (BOT). Among other things, the BOT is responsible for developing a license implementation plan and assessing the feasibility of developing a unified recreational fishing license for fresh and saltwater fishing. The initial report of the BOT is due to the JLCSA on April 15, 2005.

- **Recommendation #2**—Depending on the findings of the BOT study, we would support the development of a unified license provided that data could be generated that accurately identifies those anglers that fish in saltwater. We will work closely with DMF and WRC on this issue.

- **Recommendation #3**—At this time, we do not support the use of blanket licenses for charter boats, head boats or piers. We are sympathetic to the concerns raised by these groups and support continued study of this issue to determine whether their needs can be addressed in a manner that ensures that every angler is counted. If blanket licenses are approved, sufficient fees should be applied to ensure that the Saltwater Fishing Fund does not experience a loss in revenues.

- **Recommendation #4**—North Carolina receives around $5 million dollars per year from the federal funds generated pursuant to the Sportfish Restoration Act. The General Assembly should ensure that license revenues are used in a manner that does not jeopardize the state's continued ability to receive those funds.

- **Recommendation #5**—Good enforcement is a critical component of effective fisheries management. We recommend that the law be amended to allow that some portion of license revenues can be used for law enforcement. In the meantime, we support full funding of the Division's expansion budget request for more marine patrol officers.

- **Recommendation #6**—In order to ensure that the license program is efficient, effective and customer-friendly, the Division needs adequate funding to develop and operate it. We support full funding for the program.

- **Recommendation #7**—The law provides for a seven day license for $1. This fee will not even cover the cost to process the license application. We support the Division's recommendation that this short-term license be extended to 10 days and that the fee be set at $5. There need not be a limit on how many can be bought in one year.

- **Recommendation #8**—The fee for an annual license is $15, regardless of whether you are a NC resident or from out of state. Most other states charges non-residents a higher fee (often $5 to $25 more). We recommend that the law be amended to impose a higher fee on non-residents. (SC charges residents $10 and non-residents $35 for an annual license. Every other state from Maryland to Texas, except Virginia, charges a higher fee for non-residents.)

- **Recommendation #9**—We support the Division's recommendation that data on recreational licensee be made available to the public.

- **Recommendation #10**—We support extending the effective date of the license requirements in order to provide a reasonable amount of time to get the program up and running. We agree with the Division that a realistic effective date is January 2, 2007.

JLCSA meeting November 18, 2004

Thanks to Chairs and members of the Commission

SW License-

MFC has twice endorsed ~~the~~ a Saltwater license, based on the recommendations of the MSC - urge you to compare the '04 version from legislature to the earlier models and ~~modify to reflect the~~ consider MSC recommendations.

After legislature passes and modifies the license- unless you fish in saltwater, you are through with the license. Imperative that you remember who is left to use, implement and enforce those provisions- anglers, the DMF and the MFC to some degree. Modifications must have provisions to fund DMF for implementing, administering and enforcing the program and providing services for the anglers- these are not small nor unimportant tasks. Remember that there are an estimated 2 million anglers.

- blanket licenses for piers and charter boats w/ requirements for logs to submit names of anglers to DMF- For Hire ~~survey~~ permit already in place for charter boats and piers are probably simplest fishery to sample efficiently + effectively. ID charter operations

- paperless licence is a great idea, but we must have some way to enforce compliance. Simply asking an angler to give his name and address will not suffice. Verification is dependent on instant (Satellite??) communication available to Marine Patrol- already carry guns, radios, and more.- more training and less time on the water. All anglers and hunters EVERYWHERE are used to and comfortable with carrying a license- or at least being able to prove they had one at a future time. WRC enforcement deals with this every day.

- BUT- the DMF needs money for enforcement- $$ for enforcement was recommended by the MSC and is necessary to have an effective license and insure compliance with regulations.

- MFC has not discussed, but **MY OPINION** that A $1.00 license is not a reasonable way to provide one-time users with a break. Substantial costs in administration AND tracking to prevent abuse (HOW IS THE ISSUER GOING TO KNOW THAT THE PERSON HAS PURCHASED ONE BEFORE?). $5.00 - $7.00 for a one week license is very reasonable and then no-one has to worry about whether a person has purchased a license previously.

* - effects on W-B funds - input to DMF & WRC

* - meetings - don't neglect us W of 95 lots of fun do here

suggest SW lic w/ $5.00 freshwater rider

Coastal Recreational Fishing License Survey

Final Report

North Carolina State University

John Whitehead
East Carolina University

Ron McPherson
Winston-Salem Saltwater Sport Fishing Club

with the assistance of

Jack Thigpen , UNC Sea Grant

Vernon Kelly, Coastal Carolina Community College

SALTWATER FISHING LICENSE

CHANGES NEEDED:

- Paperless license is not workable – need paper license
- Need money for Enforcement
- Need appropriately qualified people to serve as Fund Board members (ex. primarily recreational fishermen including a marine scientist, an environmentalist, a biologist, an educator, etc.)
- Increase $1.00 weekly license to $5.00 – at $1.00 no one will want to sell them
- Need a Blanket license for Charter Boats
- Grandfather the Wildlife Lifetime License to include saltwater fishing

Further input or clarification: Ron McPherson – 252-726-2762

The research on which this report is based was financed by the UNC Sea Grant Program. Contents of the publication do not necessarily reflect the views and policies of the UNC Sea Grant Program and the mention of any trade names or commercial products does not constitute their endorsement by the North Carolina Government.

August, 1999

Executive Summary

The purpose of this study is to better understand the knowledge and attitudes of coastal recreational anglers relative to a range of issues affecting North Carolina fishery resources. Information was collected through a scientific survey of a random sample from each of the following groups:

- 100 saltwater sportfishing club members (interviewed by telephone);
- 200 commercial license holders who did not have endorsements to sell (interviewed by telephone); and
- 300 point-of-contact interviews with anglers along the coast (in-person).

Particular attention is paid to the evaluation of alternative management strategies, including a coastal recreational saltwater fishing license. The results will be used to develop strategic policy recommendations and practical action that can be taken to better protect the saltwater fisheries resources of the state. A determination is also being made of public support for and willingness to pay for the license.

All respondents had fished in saltwater during the previous 12 months in North Carolina or off its coast. The average number of days spent fishing in saltwater was 30. The average number of years respondents have been fishing along the coast was 27. The majority of respondents regularly read fishing or boating magazines, but only a small percentage belonged to conservation organizations. Fishing club members were more active in both of these activities than either license holders or point-of-contact anglers. Most respondents already had freshwater fishing licenses. The fishing gear used most often were rods and reels. Other results show that: the average number of trips was t

26 per year; the average catch is 10 fish; the average distance traveled to fish is about 99 miles; and average costs per trip is $229.00. These vary for each group.

Respondents from all groups expressed general satisfaction with saltwater fishing in North Carolina. However, over half of all respondents rated saltwater fishing along the coast as fair or poor. When asked to compare fishing today with five years ago, nearly half rated it as worse; and about a third rated it about the same. Few rated fishing today as better than in the past. Of those who thought fishing was worse, the reasons mentioned most often included: over-fishing by commercial fishermen, pollution of estuaries, and excessive netting.

There is clear support for a wide variety of alternatives for managing the saltwater recreational fishery in North Carolina's coastal area. A majority of individuals from the overall sample supported each of the following:

- more research (86%);
- increased monitoring of fishery conditions (85%);
- limits on minimum size of fish (84%);
- stronger laws to prevent loss of wetlands (83%);
- educational programs (79%);
- limits on number of fish (78%);
- public money to purchase land for buffer strips (73%);
- mandatory certification in catch and release techniques (65%);
- specific allocations and closure when quotas are met (62%);
- limits on times of the year (55%);
- limits on areas (51%);
- a saltwater fishing license (50%).

There is less support for the saltwater fishing license among license holders license holders (44%) and point-of-contact anglers (42%) than among club members (80%). However, support increased significantly among all groups when respondents were told about the conditions under which the money from the license would be used. Respondents were asked later in the interview if they would purchase the Coastal Recreational Fishing License (CRFL) at *"a cost of $15.00 if the money raised would go into a dedicated fund to improve coastal recreational fishing through habitat restoration, better enforcement, expanded research, and education. The license would also help the NC Division of Marine Fisheries get an accurate count of the number of recreational anglers."* Overall, **78 percent** of all respondents would purchase the annual CRFL under these conditions. In fact, when told that additional funding might be needed to fund improved fisheries management, 46 percent said they would be willing to pay more than $15.00 for the license. In addition, over a third (37%) of those who would not purchase the annual CRFL would purchase a one-week CRFL. Overall, **84 percent** would purchase an annual or one-week license.

The annual revenue generated from the CRFL fees will be about $11 million. A more rigorous analysis of the economic benefits of improved fishing was conducted using willingness to pay data. The maximum willingness to pay for the license is an estimate of the value of the increase in the quantity and quality of trips. Results indicate that the club sample would be willing to pay almost $100 more for the annual CRFL, license holders would pay $70 and point-of-contact anglers $47. A conservative estimate of the annual benefit from the CRFL derived from the willingness to pay analysis is that anglers wold be willing to pay $23 million for improved fishing.

In summary, there is clear support for the proposed CRFL, if the money raised is used as proposed by the Moratorium Steering Committee.

ACKNOWLEDGMENTS

We would like to thank a number of people for their assistance and valuable insight. The authors gratefully acknowledge help received from:

- All the anglers who participated in the study

IV. SUMMARY AND CONCLUSIONS

Most of the respondents are avid anglers. All reported fishing in the last 12 months, with fishing club members fishing 34 days on average, license holders 26 days and point-of-contact anglers, 30 day. The average number of years respondents have fished is 27. More time is spent fishing from a boat followed by the beach and piers.

While the respondents are avid anglers, most do not belong to either conservation organizations or fishing clubs. However, the majority do regularly read fishing or boating magazines and have freshwater fishing licenses. Very few have a commercial fishing license. The fishing gear used most often is rods and reels.

The majority of respondents rated fishing today in North Carolina coastal waters as fair or poor. This was the case for all sample subgroups. When asked to compare fishing with five years ago, over half reported that fishing is worse. Most of the blame is placed on over-fishing by commercial license holders, followed by pollution of estuarine waters.

Most anglers generally support a number of different alternatives for managing the saltwater recreational fishery in North Carolina including more research, increased monitoring of fishery conditions, limits on size and number of fish caught, stronger laws to protect wetlands, educational programs and a saltwater recreational fishing license. While a majority supported a license, it ranked lowest in priority. When respondents understand that money generated for a license will be used for fisheries management, the percentage supporting a license increases significantly. Also, club members were most supportive and point-of-contact anglers least supportive of these alternatives.

The number of fishing trips taken in the past twelve months is 26, with fishing club members taking 31 and the other two groups taking 25. In all cases, most trips are one-day trips. Most fish for "anything that is biting" but fishing club members and

license holders are much more likely than point-of-contact anglers to target specific species, such as king mackerel, spot and flounder. The typical catch is 10 fish per trip.

The average number of miles traveled in a typical fishing trip is 99 miles one-way. The average total cost per trip is $229.00. Fishing club member spend more, on average, than the other two groups, due mostly to higher lodging and fuel costs.

People were told that the CRFL would be required for anyone who fishes in North Carolina coastal waters and that all the money raised who go in to a dedicated fund for habitat restoration, better enforcement, expanded research, and education. Respondents were also told that the license would help the Division of Marine Fisheries get an accurate count of the number of recreational anglers. Under these circumstances, 78 percent of the respondents would purchase the annual CRFL. Of those who would not purchase an annual license, thirty-seven percent would purchase the one-week license. Overall, 84 percent of the anglers interviewed would purchase a CRFL. Club members and point-of-contact anglers were most likely to purchase either an annual or one-week license. Clear support for the CFRL. This is true even for comparisons by region, number of times fish, and shore versus boat fishing. Of the very few not willing to buy purchase a license, the reason given for not purchasing is that the respondents do not support it or feel it is unfair.

Additional support is found when respondents are asked if they would be willing to pay more money to fund improved fisheries management. Overall, 46 percent of those willing to purchase a license, would be willing to pay a higher fee. Fishing club members are the most willing to pay higher fees. The maximum willingness to pay estimates are $90, $70, and $47 for the fishing club, license holders, and point-of-contact samples.

The annual revenue generated by the CRFL from North Carolina and out-of-state anglers would be about $11 million. The total benefits of the CRFL are $23.6 million derived from estimates of the number anglers and the willingness to pay estimate from point-of-contact anglers. The total costs of the North Carolina CRFL, the sum of lost economic benefits from those who cease to fish and from administrative costs, would be $2.65 million. An estimate of the annual benefit (net benefit=benefits - costs) of the CRFL to North Carolina is $21.05 million ($23.6 million minus $2.65 million).

Most respondents agreed:

- that the license is a good idea if used for the estuaries;
- that the money raised would help the fisheries;
- that recreational anglers need to pay to manage the fishery;
- that the license would provide managers with better information;
- that it is important to keep track of the number people fishing; and
- that the saltwater license should help just as the freshwater license has helped.

However, most disagreed that government listens to the concerns of recreational anglers.

When asked to divide each dollar raised by a license for resource enhancement, law enforcement, research, and public information, the respondents distributed the money in almost the exact proportions as recommended by the Moratorium Steering Committee. The respondents would allocate 31 cents for resource enhancement, 22 cents for law enforcement, 26 cents for research and 21 cents for education. Generally, a similar pattern prevails for each sub-group.

Respondents were asked a number of questions concerning their attitudes and behavior related to fisheries management. The majority of respondents feel that the government is doing too little to manage the fisheries in North Carolina. Fishing club

members are most likely to feel this way. Interestingly, the majority of respondents have never attended a public hearing or contacted a government agency to voice concerns about fishing. However, nearly 70 percent of club members have done so. Most have never contributed money to a fishing cause. Among fishing club members, 86 percent have contributed money. Most respondents have some or a little trust or confidence that the government will effectively protect North Carolina's fishery. Not many have a lot of trust. This pattern is similar for each group.

There appears to be clear support for the CRFL when anglers understand that the money generated from the license will be used to manage the fishery. Furthermore, there appears to be positive attitudes about the impact of a license. There is strong sentiment that the license would help the fisheries in North Carolina, that recreational anglers need to pay to help manage the fishery and would provide better information for fisheries management. In addition to supporting a recreational license, anglers are supportive of other management alternatives as well, including research, monitoring fishery conditions, limits on size and number, mandatory certification in catch and release techniques, educational programs, stronger wetland laws and so on. A much greater commitment to education will be needed to build and maintain support for fisheries management programs.

Comment on HB 831
An Act to Establish the North Carolina
Recreational Saltwater Fishing Fund and License
To the Seafood and Aquaculture Committee of the Legislature

Honorable Chairman and Honorable Members of the Committee, my name is Larry Coble. I would like to thank you for being allowed to speak to you today on this very important issue. I own and operate a charter boat in Southport, NC. I have long been in favor of a Recreational Saltwater Fishing License (RSFL) and was a participant in the meetings of the Moratorium Steering Committee meeting chaired by Bob Lucas. I was president of the Winston-Salem Saltwater Sport Fishing Club in 1998 and 1999. During this time the Club obtained funding from Sea Grant and conducted the North Carolina Coastal Recreational Fishing License Survey of 1998 (Survey of 1998). This survey showed that 84% of the individuals surveyed were in support of a RSFL with certain conditions.

While I feel that HB 831 is a great step in the right direction. I feel that in order for a RSFL to be successful there are several additional items required. The years of work by the Moratorium Steering Committee and results of the Survey of 1998 should not be ignored.

During this past year approximately 70% of the people fishing on my boat were from out of state. These included people from all walks of life, from Governor Easley's brother and nephew, to man and wife truck driving teams from Idaho hauling munitions to Sunny Point Ordnance Depot for shipment to Iraq. The latter got into town a day early and wanted to go fishing because they couldn't unload the munitions over the weekend. Based on my experiences, I have four (4) issues that I would like for you to consider in refining the intent of HB 831.

Issue I: One of the conclusions of the Moratorium Steering Committee and the Survey of 1998 was that blanket licenses should be issued to charter boats. I feel that it would be an extreme burden on me as a small business owner and operator to have to advise my customers that in order to fish on my boat they had to obtain a RSFL. A majority of my customers arrive in town late on Friday evening and the boat leaves the dock at 6:30 am the next morning. If any of you have ever been to Southport you would find it very difficult to find many places open during those hours. It would appear to be better for all concerned to just allow the boats to be licensed rather than the individuals. Marine Fisheries already has in place the mechanism to license charter boats. We currently are required to be licensed, but there is no fee charged. All that is required is for Marine Fisheries to charge a reasonable license fee. If needed, I don't think it would be too much of a burden to report to the Marine Fisheries, on some periodic basis, the number of individual going fishing on my boat. It is my opinion that this blanket license should be issued only to bona fide charter boats and not made available to the recreational boaters.

I also, feel that it will be very difficult to obtain local agents to bother with issuing a RSFL for only $1.00. It just won't be profitable or worth the time for many merchants to bother with all the record keeping that I am sure the State will require. This will make it that much more difficult for individuals to obtain a RSFL on short notice.

Issue II: Under Statute 113-174.2, I am confused concerning whether as a licensed commercial fisherman, I would be required to obtain a RSFL in order to continue fishing. The commercial fishing that is done on my boat is with rods & reels, the same as is used for recreational fishing. Some clarification appears to be needed. It is my opinion that if a person is holding a commercial license, they should not be required to obtain a RSFL, also.

Issue III: Section 12. (c) of HB 831 speaks of the Board of Trustees studying the issues related to the establishment of a unified recreational fishing license for both inland and coastal fishing waters. This issue was extensively debated in the Moratorium Steering Committee public meetings and it was strongly supported that individuals who currently hold a lifetime North Carolina Sportsman or lifetime fishing license issued by the Wildlife Resources Commission (WRC) be grandfathered into the RSFL program. I also, recommend that immediate discussion be started with WRC to develop a unified recreational fishing license.

Issue IV: Statute 113-175.2 (b) Establishes qualifications for the Board of Trustees. As a long time interested party in RSFL issue, it is felt that the qualifications of the Board members should be more defined than just having a RSFL. I agree that they should have one, but they should have other qualifications as well and these should be defined in the Statute. It is suggested that qualifications of the nine (9) Board Members be modified to include the following:

1. One at large and residing west of Hwy I-77.
2. One at large and residing between Hwy I-77 and Hwy I-95.
3. One at large and residing east of Hwy I-95.
4. One with an environmental science background.
5. One with a marine science background.
6. One charter boat owner/operator.
7. One pier owner/operator.
8. One a member in good standing of a surf fishing club.
9. One a member in good standing of a saltwater sport fishing club.

Again I would like to thank you for being allowed to make comments on these issues and hope you will consider them in your deliberations and if I can be of further assistance on this or other issue, please do not hesitate to contact me.

August 7, 1996

Mr. Maury Wolff
Marine Sport Fish Restoration Program Coordinator
Division of Marine Fisheries
P. O. Box 769
Morehead City, NC 28557

Dear Maury:

I have reviewed the Report of the License Subcommittee to the Moratorium Steering Committee. I have discussed several points with the Department of the Interior Solicitor (who is familiar with the Federal Aid program and the "diversion" concerns). The following comments are provided for your consideration as you work with the Legislators in the development of a marine recreational fishing license.

Draft Report, page 3, paragraph 3.c.

The statement "advice and consent of a Marine and Estuarine Resources Enhancement Trust Fund Board of Trustees" has potential to become an issue under the Federal Aid Rules and Regulation, section 80.4 Diversion of License Fees. What I mean is that it depends on the function of the Board of Trustees. If the Board only provides advice and consent on the budget, projects, activities, and etc. that the Secretary (Division of Marine Fisheries) presents to the Board then this activity by the Board would probably not be considered diversion. However, if the Board provides specific directions and priorities, specific projects and activities for the Secretary, then this type of activity by the Board may be considered a diversion of the license fees.

Draft Report, page 33 & 34, paragraph C.

The issue of what type and/or activities that would be included in a recreational "fishing" license is the State's decision. Also the deposit of these license fees and/or other license fees into a "Trust" fund would not create a diversion of license fees. Once the license fees were collected and deposited, the expenditure of the funds in the "Trust" funds governs the issue of a diversion. Under Section 80.4 (c) and (b), the regulation states:

> (c) A diversion of license fee revenues occurs when any portion of license revenue is used for any purpose other than the administration of the State fish and wildlife agency.

(b) For the purposes of this rule, administration of the State fish and wildlife agency includes only those functions required to manage the fish and wildlife-oriented resources of the State for which the agency has authority under State law.

Therefore, as long as the collected fees were used by the Division to manage the marine fishery resources of the State of North Carolina, the diversion of license fees would not appear to be an issue.

Draft Report, page 7, paragraph 9

Under paragraph 9, there are several types of licenses being considered. It should be pointed out that issuance of a new Coastal Recreational Fishing License will not necessarily mean that North Carolina will be able to count the total number the freshwater and saltwater license sold as the certified fishing license holders. Since an individual could hold more than one license to fish the State of North Carolina and the regulation require that individuals be counted once as a license holder, the State would need to eliminate duplication or multiple count of individuals with more than one required license. Some of the special licenses would require a review to insure that they provide a net return commensurate with the period for the fishing privileges are granted.

If I can be of additional help, please give me a call at (404) 679-4159.

Sincerely yours,

Cleophas R. Cooke, Jr.

FISH AND WILDLIFE SERVICE
1875 Century Boulevard
Atlanta, Georgia 30345

IN REPLY REFER TO:

Ms. Sandy Semans
Communications Director
North Carolina Fisheries Association, Inc.
P. O. Box 12303
New Bern, NC 28561

Dear Ms. Semans:

The following information is in response to the questions in your letter of August 15, 1996.

1. If recreational fishermen buy the proposed saltwater fishing license and they already hold a Wildlife Resource Commission license, which agency can count them toward the number of resident fishermen needed for Wallop-Breaux funding?

> In the Federal Aid Rules & Regulations section 80.10(c)(5) the paragraph states that some States may require an individual to hold more than one license to fish in the State and that such individual shall not be counted more that once as a fishing license holder. The State certifying officer is responsible for eliminating duplication or multiple counting of single individuals.
>
> The certification of license holders for the State of North Carolina is done for the entire State not by individual agencies within a State. Currently, the Director for the Wildlife Resource Commission is the certifying officer for the State of North Carolina.

2. What happens to WB funding if the number of actual fishing licenses sold are less than current estimates of fishermen used on which to base funding? Will that reduce funding?

> Funding level for any State is set by the distribution ratio that is spelled out in the Federal Aid in Sport Fish Restoration Act.
>
> > "The Secretary of the Interior shall apportion the annual appropriation among the States in the following manner: 40 per centum in the ratio which the area of each State including coastal and Great Lakes waters bears to the total area of all the States, and 60 per centum in the ratio which the number of persons holding paid licenses to fish for sport or recreation in the State bears to the number of such persons in all the States. Such apportionments shall be adjusted equitably so that no State shall receive less than one per centum nor more than five per centum of the total amount

apportioned."

3. Do "special licenses" sold for reduced rates or given away have to show a net profit or are all recreational licenses grouped together to determine "profit" status.

In the Federal Aid Rules & Regulations section 80.10(c)(2) the paragraph states that licenses which do not return net revenue to the State shall not be included. Free or give away licenses could not be counted in the certification of license holders. Licenses valid for more than one year can be counted if the license fee provides net revenue commensurate with the period for which fishing privileges are granted and a technique is used to determine whether the licensee remains a license holder in the year of certification.

4. If a fisherman buys both a commercial fishing license and a recreational license, can they still be counted for funding?

Yes, but the information in question 1, 3, and 5 applies to the holders of recreational fishing licenses.

5. How would one determine the numbers of resident saltwater fishermen under proposed "blanket" licenses to be issued to charter boats and piers in lieu of their patrons holding individual licenses?

Only individual license holders can be counted in the certification of license holders for the purpose of determine in apportionment for a State.

6. Does the enhancement of the resource, such as creating artificial habitat projects qualify as administration of the agency?

In the Federal Aid Rules & Regulations section 80.4(b) the paragraph states for the purposes of this rule, administration of the State fish and wildlife agency include only those functions required to manage the fish and wildlife-oriented resources of the State for which the agency has authority under State law. If the agency has the authority under State law to create "artificial" habitats for enhancement of resource, then this activity would be a function to manage fish and wildlife resources of the State.

7. Am I correct in understanding that "diversion of license fee revenues" under the Federal Aid Rules & Regulations, section 80.4(c and b) Diversion of License Fees, refers to expenditures of a particular fund as a whole rather than "mixing" of monies from other sources? In other words, if

commercial license revenues and recreational licenses revenues are deposited in the same account, is that acceptable as long as ALL the monies are spend for fish and wildlife administration?

The "diversion of license fee revenues" applies only to the fees imposed by the State to hunt or fish for sport or recreation and these fees can not be diverted for any purpose other than the administration of the State fish and wildlife agency.

In answering the second part of the question, if the monies in an account can maintain its original identity as to the source of the revenue then the protection from "diversion of license fee revenues" would only apply to the fees imposed by the State to fish for sport or recreation. However, if monies from several revenue sources are commingled in one account and its identity is loss then the total fund would be protected by the diversion rule.

8. Am I correct in understanding that if the revenues are placed under the direct control of a board which would decide how and where the monies are spent that this could be considered diversion of funds?

The simple answer to the question is probably **YES.** But as I stated in the letter to Mr. Wolff, the question of diversion would depend on what is the function of the Board and what role it would have in providing direction and priority of the administration of the State fish and wildlife agency.

9. How much does the NC Division of Marine Fisheries currently receive in WB funding?

The State of North Carolina received in the Federal Fiscal Year 1996 (Oct. 1, 1995 to Sept. 30, 1996) a total of $3,026,314. Within the State the funds are divided between freshwater (74%) $2,239,472 and saltwater (26%) $786,842.

10. What is the current estimate of saltwater recreational fishermen on which current funding is based?

The State of North Carolina uses the 1991 National Survey of Fishing, Hunting, and Wildlife-Associated Recreation survey conduct by the U.S. Fish and Wildlife Service and the Bureau of the Census to determine the allocation of funds to freshwater and saltwater activities. According to the attached table 989,000 fishermen (74%) fished in freshwater and 347,000 fishermen (26%) fished in saltwater.

11. If recreational saltwater licenses include gear and methods different from hook and line, do resource users who hold the license but don't use hook and line have to be eliminated from the numbers used for funding?

> Under the Federal Aid Rules & Regulations, we find in section 80.4 (a) the following " licenses issued by the State conveying to a person the privilege to pursue or take wildlife or fish." In section 80.4 (a)(1) we find "recreation fees or other charges imposed by the State to hunt or fish for sport or recreation." In section 80.10 (c)(1) we find "Trapping licenses, commercial licenses and other licenses which are not for the express purpose of permitting the holder to hunt or fish for sport or recreational shall not be included." Thus, if the State of North Carolina requires a saltwater recreational fishing license that conveys to the individual the privilege to pursue or take fish for sport or recreation, then that individual license holder could be certified within the limitation described in questions 1, 3, and 5.

Under the diversion rule, one must keep in mind that it is the State of North Carolina that goes into diversion not individual agencies within a State. So if there was a problem in one of the State fish and wildlife agencies that creates a state of diversion, the State of North Carolina would be declared in diversion and all Federal Aid funds would be withdrawn. ★★★

We have enclosed for your information a copy of the Federal Aid in Sport Fish Restoration Act and the Federal Aid Rules and Regulations. If you have any question, please contact me at 404/679-4159.

Sincerely yours,

Cleophas R. Cooke, Jr.

SOURCE: FH-2 and FH-3 data files of the 1991 National Survey of Fishing, Hunting, and Wildlife-Associated Recreation.

Notes: "Saltwater anglers" excludes those who shellfished only. The number of anglers are measured directly from the 1991 National Survey for those 16 years old and older. Ratio estimation was used to add the 6-15 year old anglers, using the ratio of 6-15 year olds to all anglers from the 1991 National Survey screening phase. "Sum - Both Categories" is the sum of tabulated freshwater and saltwater anglers. Hence, it does not represent the number of individuals who fished in their State of residence (since individuals may fish in both freshwater and saltwater), but rather the sum of all residents who fished in freshwater in their State of residence plus all residents who fished in saltwater in their State of residence.

General Assembly of North Carolina
Joint Legislative Commission on Seafood and Aquaculture
and
Environmental Review Commission
State Legislative Building
Raleigh, North Carolina

November 15, 2004

Coastal Site Visit Information
9:00 a.m. Monday, November 29, 2004
Duke University Marine Laboratory

TO: Members of the Joint Legislative Commission on Seafood and Aquaculture (JLCSA)
Members of the Environmental Review Commission (ERC)

FROM: Jeff W. Hudson, Commission Counsel, JLCSA and ERC
George F. Givens, Commission Counsel, ERC and JLCSA
Cindy J. Davis, Commission Clerk, JLCSA
Mary R. Watson, Commission Clerk, ERC

RE: Coastal Site Visit

The Joint Legislative Commission on Seafood and Aquaculture and the Environmental Review Commission will visit coastal sites in the Atlantic Beach/Morehead City/Beaufort, North Carolina area on Monday, November 29, 2004.

Please find enclosed the following information related to the site visits:

- Information on accommodations.
- The itinerary for the coastal site visits.
- A map and driving directions for the Duke University Marine Laboratory and the Sheraton Atlantic Beach Hotel.

If you have questions about the Commission meeting or other matters related to the Commission, contact Jeff Hudson or George Givens, Commission Counsels, at (919) 733-2578, Cindy Davis, JLCSA Commission Clerk, at (919) 733-5705, or Mary Watson, ERC Commission Clerk, at (919) 715-3050.

Coastal Site Visits

The Joint Legislative Commission on Seafood and Aquaculture

and

The Environmental Review Commission

November 29, 2004

Atlantic Beach/Morehead City/Beaufort, North Carolina

ACCOMMODATIONS

Rooms have been blocked off at the Sheraton Atlantic Beach Hotel, 2717 West Fort Macon Road, Atlantic Beach, North Carolina for the evening of November 28. The Sheraton Atlantic Beach Hotel will hold these rooms until November 25. After this date, room availability is not guaranteed. Oceanview rooms are available at the rate of $57.25. Contact the Reservations Department at the Sheraton Atlantic Beach Hotel for reservations at 1-800-214-0258. Please advise them that you are with the joint meeting of the Joint Legislative Commission on Seafood and Aquaculture and the Environmental Review Commission.

If you have any questions, please call:
George Givens or Jeff Hudson, Commission Counsels, at (919) 733-2578;
Cindy Davis, Commission Clerk for the Joint Legislative Commission on Seafood and Aquaculture, at (919) 733-5705; or
Mary Watson, Commission Clerk for the Environmental Review Commission, at (919) 715-3050.

ITINERARY

November 29, 2004

THE JOINT LEGISLATIVE COMMISSION ON SEAFOOD AND AQUACULTURE
AND
THE ENVIRONMENTAL REVIEW COMMISSION

VISIT TO

THE DUKE UNIVERSITY MARINE LABORATORY
135 DUKE MARINE LAB ROAD
BEAUFORT, NORTH CAROLINA

Some activities will be outdoors and will include boating.
Wear comfortable clothing, rubber-soled shoes, sunglasses, and sunscreen.
Also, bring a warm jacket along.

MORNING

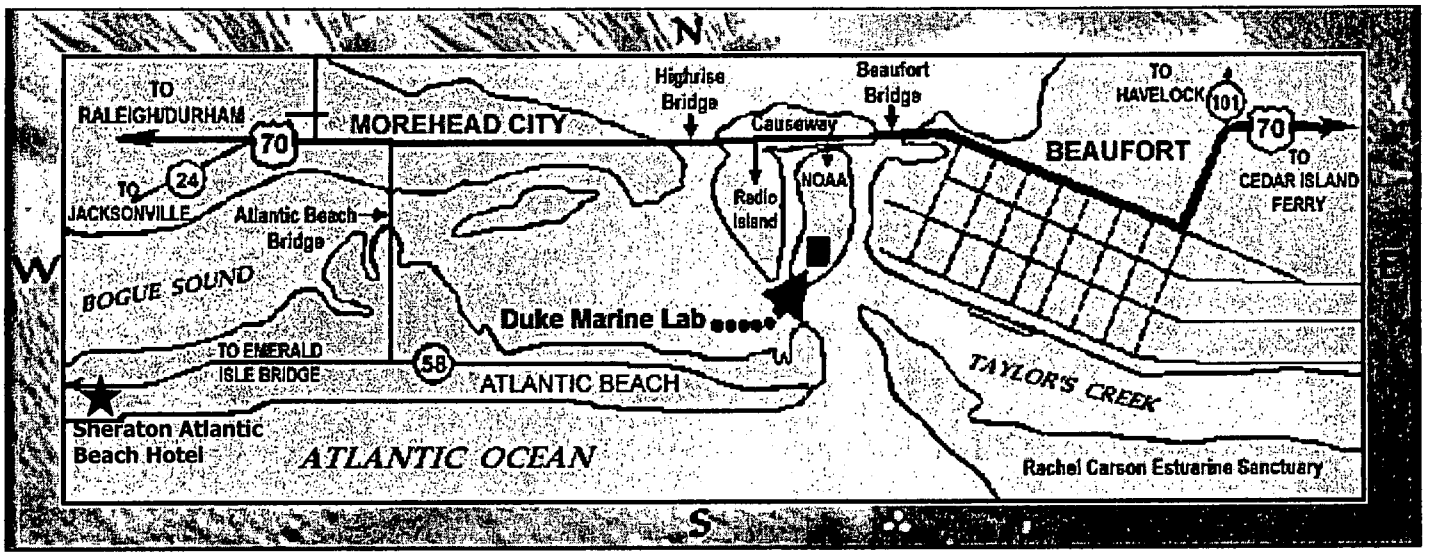
9:00 – 9:30 A.M.	Orientation – Auditorium Duke University Marine Laboratory
9:30 – 11:30 A.M.	Trawling trip aboard the *Susan Hudson, Capricorn,* and *Carolina Coast*

AFTERNOON

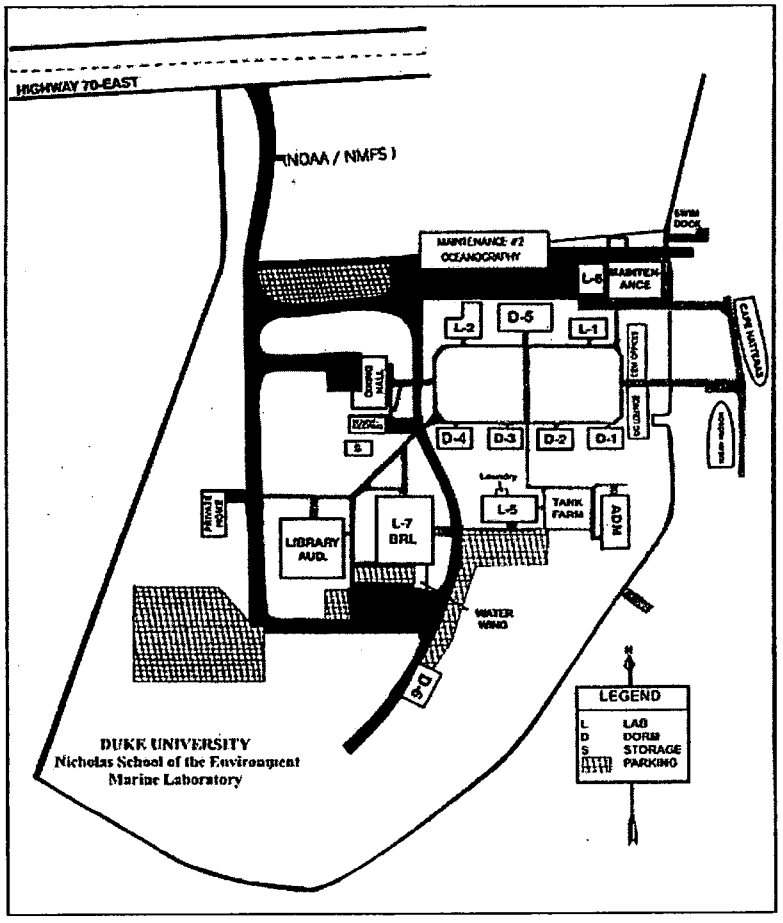
Noon – 1:30 P.M.	Lunch – Dining Hall Duke University Marine Laboratory (Lunch Provided)
1:30 P.M. – 3:30 P.M.	Boat tour of the Rachel Carson Estuarine Research Reserve

If you have any questions, please call:
George Givens or Jeff Hudson, Commission Counsels, at (919) 733-2578
Cindy Davis, Commission Clerk for the Joint Legislative Commission on Seafood and Aquaculture, at (919) 733-5705
Mary Watson, Commission Clerk for the Environmental Review Commission, at (919) 715-3050

LOCATION MAP: DUKE UNIVERSITY MARINE LAB AND SHERATON ATLANTIC BEACH HOTEL



FACILITY MAP: DUKE UNIVERSITY MARINE LAB



DRIVING DIRECTIONS TO MOREHEAD CITY

- From Raleigh, follow Interstate 40 East to Garner/Smithfield Highway 70 East Exit 306.
- Follow Highway 70 East all the way to Beaufort (through Goldsboro - be sure to take the By-pass! - Kinston, New Bern, Havelock, and Morehead City). Highway 70 East is also the main street, Arendell Street, in Morehead City.

To Duke University Marine Lab:

- Continue on Highway 70 East through Morehead City over a highrise bridge (crosses Newport River). From the base of the bridge, it is .6 miles (or second right turn) to the turn for the Duke University Marine Lab.
- Cross the railroad tracks and go straight over the very small bridge leading onto Pivers Island.
- Turn left at the third drive, or go straight to the parking lots at the back of the island.

To Sheraton Atlantic Beach Hotel:

- From Highway 70, turn right onto Atlantic Beach Bridge and cross over bridge.
- Turn right at stop light onto Fort Macon Rd. Hotel is 2 miles on the left.

DRAFT

MINUTES
ENVIRONMENTAL REVIEW COMMISSION
November 19, 2004

The Environmental Review Commission (ERC) met on Friday 19 November 2004 at 9:30 a.m. in Room 544 of the Legislative Office Building.

Representative Daniel McComas and Senator Charlie Albertson presided over the 19 November 2004 meeting. The following members were present: Senators Albertson, Dorsett, Horton, Kinnaird, Swindell and Weinstein and Representatives Fox, Gibson, Hackney, Justice, LaRoque, McComas, Weiss and Williams. Mr. George Givens, Commission Counsel, Jeffrey Hudson, Assistant Commission Counsel, Susan Iddings, Assistant Commission Counsel, Jennifer McGinnis, Assistant Commission Counsel, Tim Dodge, Research Assistant, and Mary Watson, Commission Clerk were also present.

On 5 November 2004, notice was sent to members and interested parties via e-mail and regular mail. A copy of the notice is included in the attachments to these minutes as **Exhibit A**. A copy of the visitor registration and the agenda for the meeting are included in the attachments as **Exhibits B and C**.

Representative McComas called the meeting to order and asked members to introduce themselves and tell which district they represent.

George Givens, Commission Counsel, was called on to explain the agenda.

Mr. Givens called members' attention to a large packet of information distributed to them containing several items related to today's agenda.

Mr. Givens said that he had distributed a colored map of all of the areas in the state that have some type of water quality protection program. The newest addition to this map was the Phase II stormwater. These handouts are listed as **Exhibit D**.

Mr. Givens announced that ERC would be doing coastal site visits on Monday 29 November 2004. No business meeting will be connected with these site visits.

Mr. Givens announced that the next regular business meeting is on Tuesday, 7 December 2004 at 9:30 a.m. in Room 544 and the staff public planning meeting will be held on Wednesday, 1 December 2004 at 10:00 a.m. in Room 605 of the Legislative Office Building.

Mr. Givens said that some of the items that will be included on the 7 December agenda would be reports from land resources, coastal resources, environmental health and soil and water as well as a report on wetlands.

Mr. Givens said that with regard to the January schedule, he asked members to continue to reserve the four dates of 12 January 13 January 20 January and 25 January 2005.

Mr. Givens asked visitors to sign the visitor registration sign-in sheet and asked members to sign and send forward their reimbursement forms.

Mr. Givens added that the public staff-planning meeting for this meeting was held on Tuesday, 9 November 2004 in Room 605.

Representative Gibson asked Mr. Givens if ERC would have a joint meeting with Transportation Oversight.

Mr. Givens said that ERC is charged to jointly study issues relating to underground storage tanks. Transportation Oversight had that issue on their agenda for their October meeting. ERC had a similar presentation in October.

Mr. Givens said that he has been in conversation with staff of Transportation Oversight and they are considering how best to address this issue and whether a joint meeting is appropriate.

Mr. Givens said that he has suggested 20 January 2005 for this joint meeting.

Representative McComas said that Transportation Oversight has already taken up the issue of UST's and bringing the two committees together will not take much effort.

Representative Gibson asked Representative McComas if Transportation Oversight was comfortable with where we are headed with this issue.

Representative McComas said there are some environmental issues that come into play with transportation that may be appropriate to bring up at a joint meeting.

Representative Gibson asked Mr. Givens that when the time is appropriate, he would like to have a copy of what action Transportation Oversight has taken on the issue of UST's.

Mr. Givens said that on the subject of endangered and threatened species, the staff of Transportation Oversight had looked into the possibility of an extended agenda item on this subject. He believes that a joint meeting with ERC to discuss this issue would be helpful.

Mr. Givens said there is a program sponsored by the Rural Center on 15 December 2004 at the North Raleigh Hilton from 9:00 to 4:00 p.m. on planning for the future water needs of our state.

Representative Gibson said that he had talked to several members regarding the fishing license and asked Representative McComas to have a brief discussion on the subject at today's meeting when he deemed it appropriate.

Representative McComas asked Mr. Givens to send him an e-mail message asking him to confer with the other chairs of Transportation Oversight to arrange a joint meeting.

Mr. W. Andrew Adams, Acting Chief, Onsite Wastewater Section, Division of Environmental Health, Department of Environment and Natural Resources (DENR), gave a report on the Wastewater Discharge Elimination Program (WADE).

Mr. Adams said that he has been in his current job as Acting Section Chief for the past 10 weeks and has been with the State Onsite Wastewater Program for the past six years. Prior to working with the state, he worked in local health department across the state in the septic tank program. Mr. Adams' report is included in packet in Exhibit D.

Mr. Adams said that the WADE program was created by the General Assembly in 1996. This program, based in Asheville, serve 26 western counties.

Mr. Adams said that the two main components of the WADE program are to work with local health department and identify systems are straight piping to surface waters of the state, concentrating on public watershed areas, and to help these folks locate and identify funding to repair these systems.

Mr. Adams said that in 1996, the WADE program started with two members, but in 2001, with the help of a grant from the Clean Water Management Trust Fund and the EPA, they were able to expand to 11 members on the team doing survey work.

Mr. Adams said that since the expansion of the WADE program, the team has surveyed over 4700 homes in western North Carolina and has identified 725 violations from straight piping to a stream or malfunctioning systems going into a stream.

Mr. Adams said that of the 725 violations, 229 have been successfully repaired and over half have received financial assistance channeled through the program.

Mr. Adams said that since its inception in 1996, the WADE program has survey over 19,000 homes in western North Carolina and found over 2500 violations of sewage going into streams and surface waters. Over 1200 of

these violations, to date, have been repaired, and 480 of these received some type of financial assistance through the program.

Mr. Adams said that the most important thing is that this represents almost 300,000 gallons of sewage being removed that was going into the surface waters of North Carolina.

Mr. Adams said that the WADE program provides a win-win situation from the environmental standpoint in that it eliminates wastewater discharges, protecting watersheds and protecting public health.

Representative Weiss asked Mr. Adams how the progress is going with the outstanding violations and what is the timeframe on these.

Mr. Adams said they have a database for tracking violations and staying in touch with local health departments to keep them moving forward.

Mr. Adams said that often times the failing systems are with people with limited income and some are resistant to accept financial assistance. On the county level, legal action sometimes has to be taken. Because these are considered misdemeanors, they are sometimes slow in moving through the court system.

Senator Dorsett asked Mr. Adams to what extent is straight piping a problem in other parts of the state and what are the plans to expand to other communities.

Mr. Adams said this problem is not limited to western North Carolina. He said he would love to see the program expanded to address statewide problems. The program has gone into Halifax County to assist with a small community there to get them off of outhouses.

Mr. Adams said the WADE program has recently worked with a property owner in Onslow County to help get some financial assistance.

Senator Dorsett asked what criteria are used to move beyond the 26 counties.

Mr. Adams said that the criteria now being used is surveying of public water supply watersheds.

Senator Horton asked if violations are given a notice of violation.

Mr. Adams said that the people who are self-reporting on the WADE program, they would not be issued a violation; however, there are cases where some notice of violation is needed.

Senator Horton asked Mr. Adams how many notices of violation have been issued.

Mr. Adams said that he could get this information for Senator Horton.

Senator Horton asked Mr. Adams to provide him with a sample of the letter give notice of violation.

Mr. Adams said he would do this.

Representative McComas asked Mr. Adams to provide this information to all ERC members.

Mr. Givens asked Mr. Adams to send the sample letter to him and he would distribute it to members.

Senator Albertson asked Mr. Adams how many folks have the resources to correct the violation but are not in compliance.

Mr. Adams said that those are the ones who would show up in the database as those who are dragging their feet. These people would be sent a notice of violation and would be worked with through the court system.

Senator Albertson said that these people should be made to comply and held responsible.

Representative McComas asked Mr. Adams if we are seeing more use of blue water coming out of wastewater treatment plants to be used for irrigation purposes.

Mr. Adams said that in the Division of Environmental Health, they do not see much of the reuse of water for irrigation. This is permitted through the Division of Water Quality.

Mr. Givens said that as a follow up to Senator Dorsett's question, does DENR have plans to come forth with a budget proposal to expand the WADE program to other parts of the state.

Mr. Adams said he is uncertain as to whether or not a formal proposal has been put together at this point but would check on this and get back to him.

Mr. Givens asked Mr. Adams to follow up with him and Senator Dorsett with this information.

Mr. Givens noted that a colored map had been handed out to each member showing where all of the public water supply intakes are in the State. This handout is listed as **Exhibit E**.

Mr. John N. Morris, Director, Division of Water Resources, DENR, gave a report on the programs, activities, and priorities of the Division of Water Resources (DWR). A copy of the Division of Water Quality 2004 Organization Chart was handed out and is listed as **Exhibit F**.

Mr. Morris said that the most important mission of DWR is to make sure we have an adequate supply of water for North Carolina's future. To do that we have to have a partnership effort with local governments and with other water users who are involved in delivering this water to customers.

Mr. Morris said that in order to be successful in this task, three things have to be accomplished: monitoring, planning and regulation.

Mr. Morris said that monitoring is getting the essential data needed to expand the water resource and managing it properly. In terms of surface water, monitoring is done in streams through a network of stream gauges in partnership with the U.S. Geological Survey.

Mr. Morris said that many of these gauges have records that go back 50-75 years which gives a very good understanding what to expect from a drought, wet year or a normal year.

Mr. Morris said that to monitor groundwater availability, DWR operates about 500 monitoring wells across North Carolina. These wells monitor the water level in aquifers and tell whether groundwater withdrawals are sustainable. They are the danger signs that show if we are taking out water faster than it can recharge.

Mr. Morris added, that in addition to the monitoring of water levels, water use monitoring is needed to determine how much water we are using so that we can determine the impact on our water resources. The local water supply plans give an excellent database on how much water is being used by municipalities.

Mr. Morris said that large water users over 100,000 gallons a day are required to register their water use. This gives us good information on industry and agriculture.

Mr. Morris said that the NC Department of Agriculture has recently done a special survey of water use in the 15 county central coastal plain areas. This is by far the most detailed water use data survey we have ever had. This survey showed that agriculture uses much less water than we originally thought.

Mr. Morris said the second part of strategy is planning. Planning means that they forecast water needed for future use and select the best sources to meet that future need. These sources must be sustainable and cost effective.

Mr. Morris said the General Assembly created an excellent system for water supply planning in 1989, requiring all local governments to prepare water supply plans. These plans are updated every five years. These plans are on the DWR website.

Mr. Morris said the water supply plans contain a 30-year projection for future water needs and the designation of sources to meet those needs.

Mr. Morris said the third part of the program is regulation. There are some cases where the level of water use threatens to deplete a water supply. The General Assembly has provided the Water Use Act, which is the primary water use regulatory mechanism in North Carolina.

Mr. Morris said that the Water Use Act allows the Environmental Management Commission to declare a capacity use area within a specific geographic area where there is a danger of depleting water resources and then develop a custom made permitting plan for that area.

Mr. Morris said that is only one of these capacity use areas in existence, the 15 county central coastal plain capacity use area.

Mr. Morris said that another regulatory statute is the regulation of surface water transfers, which the EMC manages.

Mr. Morris said that several other regulatory statues that are important include The Dam Safety Act, an act that requires the owner and operator of dams to release an adequate flow from the dam to maintain aquatics habitat and other water needs downstream and The State Environmental Policy Act, a mechanism that allows the impacts of a future water withdrawal to be quantified and studied.

Mr. Morris said that the central coastal plain capacity use area demonstrates how monitoring, planning and regulation work together.

Mr. Morris said that it is extremely gratifying to see how hard local governments have worked and how effectively they are finding solutions to this problem.

Mr. Morris said that Kinston, Lenoir County and several smaller communities formed a new water authority and are developing a surface water source to use water from the Neuse River. Farmville and Greene County were a couple of water users who at first glance did not have an obvious source to go to. They have entered into a creative agreement with the City of Greenville's Utility Commission by which Greenville will sell them water on an interruptible basis. For the peak periods that they do not buy water, Farmville and Greene County will use their groundwater supplies to provide their needs.

Mr. Morris said that water banking is another concept being developed. Some of these communities are going to reduce their withdrawals of groundwater much faster than the 16 year transition period provides and will essentially bank the water they are not withdrawing from the groundwater for use when they need it.

Mr. Morris said that Onslow County and Jacksonville are moving to the Castle Hayne aquifer and a number of other communities are working out their solution. What had been a big threat to the economy of this region is now being solved and we are well on our way to having water sources that will be sustainable in the future.

Senator Horton asked Mr. Morris if any improvement in the situation has been recognized in the central coastal plain capacity use plan.

Mr. Morris said that no improvement has been seen, yet, because the reductions will take place in 2008. Due to the water-banking concept, some of the users are going to make more rapid reductions, early, so they should learn a lot from this. They will see how quickly the aquifer responds to that reduction.

Representative Justice asked if monitoring is in place to make sure that the current users of the Castle Hayne aquifer will not get into trouble and have to move somewhere else.

Mr. Morris said that the new wells being put in the Castle Hayne aquifer are also subject to permitting. Those permits are subject to public hearing and review by his staff and they think they are ahead in preventing such a problem occurring.

Representative Weiss asked Mr. Morris to comment on sedimentation and the impact it has on water supply.

Mr. Morris said that sedimentation is thought of as one of the most serious water pollution problems. It has two impacts on water supply—it makes it more expensive and difficult to treat it. Probably one of the most important, long-term impacts is that in the piedmont and mountain reservoirs, sediment tends to settle out in the upper end of the reservoirs when the water slows down as it hits the lake. Gradually, the deposit of that sediment is reducing the storage capacity of the reservoirs.

Senator Weinstein asked Mr. Morris about inter-basin transfers and if the Cape Fear and Neuse are cooperating now with transfers.

Mr. Morris said that the Cape Fear basin has had many battles with inter-basin transfer. The General Assembly has created a regulatory program for inter-basin transfer and Cary had to get a permit under that program for transfer of water from the Cape Fear River Basin. As a part of that issue, a long-range water supply plan was developed for the Cape Fear Basin and some 50-year water use projections were developed. This has become the pilot project for water supply planning across the state.

Mr. Morris said that the main secret for solving these water supply battles is to have good data and good analysis that everyone has confidence in.

Senator Weinstein asked Mr. Morris what is done to address the problem when an aquifer drops eight feet that is supplies a major industry.

Mr. Morris said that the southern coastal plain, which is the area that encompasses Lumberton, Bladen County and Elizabethtown, has an issue with use of underground water supplies, which is similar to the central coastal

plain. Fortunately, it is not as bad, yet and not as far advanced. The EMC asked WRC to do a special study of that region and considering all of the information, they are trying an approach to solve that problem which is a little different.

What the EMC has said is that there is too heavy a withdrawal by one industry and there is a gradual decline in aquifer levels throughout the region. If local governments can come up with a plan to make sure that the water use moves toward a sustainable basis, they will not need to have a regulatory program for that area. So, the EMC adopted certain guidelines to judge whether progress is being made. They are fortunate that the Lumber River council of governments has taken a strong lead in bringing people together to work toward a sustainable water supply plan.

Senator Weinstein said that he had been told that the battle will not be over oil but will be over water.

Senator Kinnaird asked Mr. Morris about water reuse. Is this a possibility in a giant hog slaughtering business.

Mr. Morris said that water reuse and water conservation are an important ingredient in meeting our future water needs. A number of communities throughout North Carolina are experimenting with this type of water reuse. To the extent that we can reuse water and become more efficient in the way we use water creates a new element of water supply to meet our future needs.

Senator Kinnaird asked Mr. Morris if the slaughterhouse water could be cleaned up for reuse.

Mr. Morris said that water from an animal processing plant, after it is properly treated, could be used for irrigation and there are many opportunities for that.

Mr. Morris said the General Assembly has been very active in giving guidance and tools for water conservation.

Mr. Morris said that water conversation is used in two different terms. One of the meanings is what occurs when there is a drought—emergency water conservation. At this time, we need to use less water during this period. The North Carolina Drought Council was recently given status in managing droughts. They will issue official scientific bulletins to identify which part of the state is affected by a drought and how severe it is. This gives local governments and water users very good information on how bad the problem is and helps them be prepared to manage their resources properly during a drought.

Mr. Morris said that another enactment by the General Assembly has made it mandatory for local governments to have a drought response plan. This is part of their local water supply plan. They are currently being evaluated by DWR.

Mr. Morris said that the General Assembly recently called upon the EMC to develop an administrative rule that would set minimum standards for water conservation during droughts. DWR and EMC are working on this together. It has become complicated because the statute applies to all kinds of water users—municipalities, industry and agriculture.

Mr. Morris said that the rule also raises the issue of what the proper sphere is for state standards and what the proper sphere is for local government autonomy and judgment.

Mr. Morris said that another word used for water conservation is water use efficiency—using less water to get the same job done. To the extent that they can become more efficient, it benefits the water user and everyone else if we become more efficient in using water.

Mr. Morris concluded by listing a couple of priorities of the DWR, better groundwater monitoring and river basin water supply planning.

Mr. Morris said that the General Assembly provided additional resources to help expand the program statewide and they are now underway for developing a 50-year plan in the Catawba and Yadkin basins. These two are being done first because of utility relicensing is underway in these two basins.

Mr. Morris said that the Neuse and Tar basin plans will be developed. The value of a 50-year plan is that it gives early warning of future problems and helps make good 20-30 year plans.

Senator Swindell asked Mr. Morris to comment on interbasin transfer permits and who is responsible for submitting a permit. He also asked Mr. Morris to comment on how much water a day is being transferred to Virginia Beach in the 85 pipeline and how much water is being transferred now, in gallons, from other basins in North Carolina.

Senator Swindell asked Mr. Morris to explain what it means when local governments have not yet submitted a water supply and if that carries a penalty.

Mr. Morris said that they anticipated that about 585 water systems should prepare local water supply plans, and as yet, they have not received plans from 60 of the systems. There is no immediately penalty applied but there are incentives.

Mr. Morris said there are some real incentives for doing the plans. Counties without a plan cannot apply for grant monies and face a more stringent procedure when they want to expand their water lines.

Mr. Morris said that with regard to the interbasin transfer issue, the Lake Gaston pipeline was difficult because no part of that system was in the State of North Carolina and the state had no jurisdiction over it. When the

North Carolina interbasin transfer law grandfathered previous interbasin transfers, it really did not have anything to do with the Lake Gaston transfer because it was outside of our jurisdiction.

Mr. Morris said that last year when re-licensing was being done for the Dominion Generation Hydroelectric projects on the Roanoke, an agreement was reached with Virginia Beach that would require them to go into water conservation measures whenever they are needed in North Carolina from the Roanoke. In other words, during a severe drought on the Roanoke, Virginia Beach would use the same level of conservation that we do in North Carolina.

Senator Swindell asked Mr. Morris how many gallons of water are currently being transferred in North Carolina.

Mr. Morris said that the Lake Gaston pipeline transfer to Virginia Beach is the only transfer being done in our state at this time.

Representative Gibson asked Mr. Morris if that sets a precedent for us as it relates to South Carolina.

Mr. Morris said the Catawba and Yadkin basins are similar in that the headwaters in North Carolina flow into South Carolina. It is complicated by the fact that on both rivers there are both hydro powered lakes operated by utility companies, which are regulated by the federal government. Currently, these are under re-licensing.

Senator Albertson asked Mr. Morris what we can do from here on out to make sure we protect our water resource to make sure we have adequate supplies for the future.

Mr. Morris said that we are on the right track. The two priorities for the next few years would be to improve groundwater-monitoring network and continue to do long-range river basin planning for the state.

Senator Albertson asked Mr. Morris if he feels like they have the resources to carry out these plans.

Mr. Morris said there is a budget item in the mill.

Mr. B. Keith Overcash, Director, Division of Air Quality, DENR, gave a report on the programs, activities, and priorities of the Division of Air Quality. A copy of Mr. Overcash's slide presentation was handed out and is included as **Exhibit G**.

Mr. Overcash gave some background on the ozone standard. The ozone standard was litigated in the court for a number of years, upheld by the Supreme Court and once it was upheld, the EPA moved to require the states to make sure they were in compliance with the standard and to delineate areas to make sure we are in attainment with the standards.

Mr. Overcash reviewed the Nonattainment designation timeline for ozone. In June 2004, nonattainment new source review requirements came into effect for large emitters of NOx and VOC compounds in North Carolina. In one year from June, transportation conformity comes into play and within three years, a state implementation plan (SIP) has to be in place and in five to six years, attainment has to be reached in all of the areas.

Mr. Overcash showed a slide on where we have been and where we have come to at this point in the attainment of the one hour and eight hour standards. The numbers have come down in the last two years and there are reductions that have taken place to reduce these numbers.

Mr. Overcash said that the Hickory Unifour area is one of those areas in nonattainment. Based on the information in the 2004-year, they will go back to EPA to have this area designated in attainment, along with the Fayetteville Cumberland County area.

Mr. Overcash said that Edgecombe and Nash County and Triad/Triangle/Charlotte-Mecklenburg areas are still in nonattainment.

Mr. Overcash said that the Early Action Compacts (EAC's) are compacts between local and state governments and EPA to try to do things that will get cleaner air, sooner. These four areas of the State entered into these compacts in December 2002. The mountain area attained compliance with the standard before EPA made the designation, so although some of the counties are still working toward local measures to reduce emissions, they are no longer an official EAC because that area is in attainment.

Mr. Overcash said that those who signed the compact in December 2002, the local people had to submit a list of measures they planned to implement by December 31, 2003. March 31, 2004, the local plan was submitted to the state and by April 2004, EPA had to designate the areas they thought were doing a good enough job to be deferred from noncompliance. Our three EAC areas in North Carolina were designated as compact areas and had the nonattainment deferred in those areas.

Mr. Overcash said that by December 31, 2004, we have to submit a SIP to EPA on those EAC's for approval. In 2005, areas implement local control measures and in June 30, 2006, progress assessment and report to EPA and December 2007, areas must attain the eight-hour ozone standard.

Mr. Overcash said that the PM-Fine Standard is a new standard with a similar history to the ozone standards. It was litigated in the courts and upheld and EPA required the states to start measuring for the standard. The standard itself is 15 micrograms per cubic meter, an annual arithmetic mean concentration over a three-year period. The 24-hour concentration is 65 micrograms per cubic meter.

Mr. Overcash said that North Carolina's recommendation to EPA in February on the areas they thought to be in nonattainment. There are only

two monitors that show nonattainment for the particulate matter (PM) standard at this time.

Mr. Overcash said that EPA responded to their recommendations and based on their information, their proposal would be for us to have more extensive areas of non-attainment for PM fine, the five counties in the triad areas, Catawba, Caldwell and Burke counties in the Unifour area.

Mr. Overcash said that Randolph County was another county EPA wanted to include. Most of the emissions in Randolph County are mobile source emissions. There are already systems in place at the federal level to reduce these emissions.

Mr. Overcash said that EPA also included Stokes County because of the Belews Creek Power Plant.

Mr. Overcash said that there are already measures being taken by North Carolina—the Clean Smokestacks Act and the Inspection Maintenance Program for automobiles.

Mr. Overcash said that another federal action taking place is the New Source Review Permit changes. EPA came out with two changes to the NSR rule, one in December 2002 and one in August 2003. The 2002 rule changes were rules to change applicability requirements.

Senator Horton asked Mr. Overcash to explain what a New Source Review is.

Mr. Overcash said that a NSR is a permitting program that is required of major facilities in the state that are major emitters of pollutants. If they want to make a modification that is called a significant modification, they have to go through a NSR process to determine what type of controls they have to put on.

Senator Horton asked Mr. Overcash if a new industry has to get permission to pollute.

Mr. Overcash said that this applies to both new and modified sources of pollution.

Mr. Overcash said that the August 2003 rule, ERP or equipment replacement provision) was a change that proposed a cost to determine whether modifications triggered a review. The ERP rule was stayed by the courts and is not moving forward at the present time.

Mr. Overcash said that in the past two sessions of the General Assembly there was a request brought before them to change the statute to allow the construction of an emissions source before an air quality permit is issued for that source. That statute was passed into law last year and allows existing permitted facilities to request construction of a source before the Division of Air Quality issues a permit. It requires public notice of the

proposed action before a facility can move forward and then they have to submit information to DAQ in order to meet certain criteria. DAQ has 15 days to make a decision on whether to approve or deny that action.

Mr. Overcash said they had received 24 requests to date and all have been approved to move forward with construction. The average turnaround time is 10 days on these actions.

Mr. Overcash said that with regard to the Clean Smokestacks Act, there was a cap on NOx and SOx emissions by EPA and the actual reductions have to be made in North Carolina. There is a requirement in the statutes that DAQ produce reports for three years and provide them to ERC for deliberation on requirements for reductions on CO2.

Mr. Overcash said that the numbers we will get from the Clean Smokestack's Act reductions in 2009 will be 75 percent NOx reductions from 245,000 tons to 56,000 tons. For SO2 emissions, we started with 489,000, the cap required to be met in 2013 is 230,000, resulting in a 75 percent reduction in emissions.

Mr. Overcash said that the carbon dioxide and mercury reports required by the statutes were provided to the ERC on 1 September 2004. These reports are included in Exhibit D.

Mr. Overcash said that the federal government has done a good job with mobile source reduction emission rule and they are counting heavily on those rules to help North Carolina get into compliance with the federal air quality standards for ozone and PM-fine.

Mr. Overcash said that North Carolina is proceeding to adopt a heavy-duty diesel engine rule even though there is already a federal standard in place. They are doing this because of some concern at the federal level that there might be some attempts to postpone that rule.

Mr. Overcash said that a number of states are moving forward on their own to adopt a rule that would basically create a defector federal rule that would require these reductions to be made throughout the United States. If the rule is put into place, the counter reductions will be achieved in the white, if they don't the emissions will continue to grow from those emission sources.

Mr. Overcash said that there are some things underway within the southeast to help reduce heavy-duty diesel emissions. North Carolina has been very active in this by giving grants to school systems within the state to retrofit school buses to reduce particulate emissions from those buses.

Mr. Overcash said there are some truck stop electrification projects underway in North Carolina where the trucks can pull up to an electrical supply at a truckstop and not burn excess fuel. There is one of these in place in Mebane and there is a grant being awarded for locating another facility in Rowan County.

Mr. Overcash said that the Attorney General filed petitions against sources in 13 states in February 2004 to ask them to reduce emissions because they were affecting air quality in North Carolina. EPA gave themselves a six-month extension of that requirement to act on this petition. They have given themselves another six-month extension.

Mr. Overcash said that on Onboard Diagnostics (OBD) testing of automobiles in North Carolina continues its expansion. Five to six counties are being added every six months and there are now 35 counties in the program. All 48 will be in by January 2006.

Mr. Overcash said that there is a significant problem resource wise with responding to open burning complaints. It has become a situation where about half of the notices of violations are for open burning and half of the enforcement cases are open burning cases. A process has been started for an outreach campaign for open burning and some of the results will be seen soon.

Senator Kinnaird asked Mr. Overcash about the open burning by DOT and about the ban on open burning in Orange County with regard to public health.

Mr. Overcash said that the problem with DOT is with their contractors understanding what the law and rules are. Training has been done with the contractors and they are informed now about what the law and rules are.

Mr. Overcash said that with regard to the open burning ban in Orange County, that is up to the county. This is not a Division of Air Quality issue.

Senator Horton asked Mr. Overcash to give specific examples of EAC's and what local governments are doing.

Mr. Overcash said that local governments are looking at their fleets to put alternative fuel vehicles in place, they are encouraging more ride share

Mr. Brock Nicholson, Division of Air Quality, was called on to give examples of what local governments are doing with EAC's. He said that the examples Mr. Overcash gave are typical of many EAC's. There are a number of enforceable measures that the counties and cities are looking at to limit emissions, fuel use and banning open burning during episode days.

Mr. Overcash said he would get a list of what counties are included in the open burning ban.

Representative Gibson asked Mr. Overcash if he could provide information on the number of variables of what DAQ is doing with regard to attainment and nonattainment. He wants to be able to explain to his folks back home what it means when they cannot get a burning permit or what it means when they have to pay more for an inspection.

Representative Gibson asked Mr. Overcash if the mobile source expansion headed the way it is supposed to be going. Are we catching enough of the newer vehicles to justify the expense to the ones who are paying it.

Mr. Overcash said he believes it is working and can provide the data to support it. There has been a significant amount of situations out there where the controls were not working properly on the automobiles and this is what is being caught.

Representative Gibson asked Mr. Overcash if we are catching enough of a percentage in the seven-year or fewer to justify the $30 charged.

Mr. Overcash said that he believes that it is working.

Mr. Nicholson said that with the tailpipe test in the nine counties were experiencing a one percent failure rate. They are averaging a three to four percent failure rate on OBD for the new vehicles. This is an indicator of the level of mechanical malfunctions and is a good balance between the severity of the test and what they are finding.

Representative Gibson asked Mr. Nicholson if we are seeing the delineation of the need for a tailpipe.

Mr. Nicholson said that based on their calculations, they are seeing any model year 10 years or older being the meat of the problem.

Senator Albertson asked Mr. Overcash what the accuracy of his models are in determining the source of emissions.

Mr. Overcash said that the modeling shows pretty well what is going on out there.

Senator Albertson asked Mr. Overcash how much of the emissions are coming from out of state vehicles.

Mr. Overcash said that he could not answer that question but would get that information to Sen. Albertson.

Senator Weinstein said that he had traveled in the mountains and has seen quite a bit of mountain area destroyed by NOx and something needs to be done to protect the air coming in from other states.

Mr. Overcash said that the federal government is trying to move forward a national standard on the power boilers. They have proposed a rule to be finalized by the end of this year. This rule would require similar reductions to the ones we are requiring in North Carolina.

Senator Albertson said that it would be nice if someone could develop a technology like NC State to determine where the source of nitrogen is coming from.

Representative Weiss asked Mr. Overcash how the light rail proposal is being used as a solution to air quality compliance and emissions reduction.

Mr. Overcash said that this would certainly be looked at as a solution.

Mr. William F. Bailey, Principal Consultant, Dupont, gave a report on issues related to greenhouse gas emissions and global climate change. A copy of Mr. Bailey's slide presentation is listed as **Exhibit H**.

Mr. Bailey said that Dupont has facilities at RTP, Cedar Creek, Fayetteville and Kinston. IT is a 202 year old global science company, with 135 manufacturing plants, 80 research and development facilities in 70 countries. The company currently has 60,000 employees.

Mr. Bailey said that Dupont is in the midst of transformation to achieve sustainable growth. The manufacturing plants are trying to achieve this by reducing manufacturing costs and reducing their energy use and emissions to reduce their environmental footprint on society.

Mr. Bailey said that Dupont has committed to meet a publicly stated level of performance by reducing greenhouse gas emissions by 65 percent versus a 1990 baseline; hold total energy use flat versus a 1990 baseline and by supplying 10 percent of total energy needs from renewable resources at a cost competitive with the best available fossil derived alternatives by 2010.

Mr. Bailey said that most of Dupont's CO2 emissions come from energy use and some from the manufacture of some refrigerants and adipic acid, which creates nitrous oxide.

Mr. Bailey said to reduce these emissions by 65 percent, Dupont had to change the way they made two very profitable products, nylon and HFC's or refrigerants.

Mr. Bailey said that Dupont spent $50 million to abate emissions in those manufacturing processes but they believe it was well worth it. Although they were not legally required to make those reductions, they have been able to meet their greenhouse gas emission goal eight years early.

Mr. Bailey said that Dupont uses what they call Six Sigma, a statistically based methodology for looking at a problem, trying to identify a defect in a manufacturing process or the utilization of energy and through the use of statistics and data, determine ways that defects, such as high energy use, can be eliminated by changing the process.

Senator Kinnaird asked if Six Sigma was used in other ways such as state government.

Mr. Bailey said that it is a statistically based process to improve an operation, the workings of government, or whatever you want to apply it to. It requires that you be able to measure your cost or whatever you want to

improve. Through the use of statistics and taking measurements of how the operation is currently performing, you are able to identify areas where defects exist that are increasing your costs, or causing your operation to perform poorly.

Mr. Bailey showed a chart where Dupont increased its production of products by 35 percent.

Representative McComas asked Mr. Bailey if that chart was based on those facilities that existed within Dupont from the 1990's on or does it take into account those facilities that have been sold and acquired.

Mr. Bailey said that Dupont goes back and adjusts the 1990 baseline based on acquisitions and divestitures.

Mr. Bailey said that the key elements of Dupont's program are having clear and measurable goals, flexibility to find the lowest cost reduction, knowing what to measure and being able to measure it in order to track progress, and to publicly report progress.

Mr. Bailey said that Dupont's goals are reported annually through the Dupont Sustainable Growth Progress Report, a 1605b report issued through the EPA.

Dr. William H. Schlesinger, James B. Duke Professor Biogeochemistry Dean, Nicholas School of the Environment and Earth Sciences, Duke University, gave a report on the current status of climate change science. A copy of Dr. Schlesinger's comments, verbatim, are included in a handout and is listed as **Exhibit I.**

Representative Williams asked Dr. Schlesinger if we have a trend set that shows North Carolina is predicting a rise in the average annual temperature in this state between 4 and 10 degrees Fahrenheit by the end of this century.

Dr. Schlesinger said the increase is mapped out over 100 years and then averaged by decade that shows that kind of an increase.

Representative Williams asked Dr. Schlesinger if the increase was one-tenth of a degree per decade.

Dr. Schlesinger said it was one-tenth of a degree Fahrenheit per decade since the late 1800's.

Representative Williams asked Dr. Schlesinger how much the average annual temperature in North Carolina had risen since 1900.

Dr. Schlesinger said it would be two degrees for the century.

Senator Albertson asked Dr. Schlesinger if we had seen a three-fold increase in the pollen count in North Carolina or would see a three-fold increase.

Dr. Schlesinger said that at the CO2 level expected 50 years from now; we get a three-fold increase in seed and pollen production. So, it is an experimentally based prediction.

Senator Albertson asked Dr. Schlesinger if we are currently seeing an increase in the pollen count or not.

Dr. Schlesinger said he did not come prepared to answer that question today and would get this information for Senator Albertson. He said he suspects there has been an increase in pollen, species by species, depending on the change in agricultural land cover in the state versus forests.

Mr. Michael J. Shore, Senior Policy Analyst, Environmental Defense, gave a report on policy options to address climate change. A copy of Mr. Shore's slide presentation is listed as **Exhibit J**.

Mr. Shore said that he would speak on solutions and opportunities for North Carolina.

Mr. Shore said that the nations of the world have come together and committed to capping greenhouse gas emissions. On February 16, 2004, the international treaty to cap global warming pollutants will come into force. The United States is not part of that treaty, but all of the rest of the major nations of the world are participating. As the nations set caps, there is a carbon marketplace that will emerge.

Mr. Shore said that for climate change, as the nation caps greenhouse gas emissions, they would then permit their polluters' allocations on how much they can pollute. Companies that can economically reduce pollution beyond their permitted level will receive pollution credits that can be sold into the carbon marketplace.

Mr. Shore said that on the supply side of the equation, there are companies who may find it more economical to buy some of their emissions reductions in the marketplace to make those reductions in-house.

Mr. Shore said that eventually, the United States will join the world in capping greenhouse emissions and when it does, the carbon marketplace will be strengthened in North Carolina as it is internationally, already.

Mr. Shore said that it is not unlikely that North Carolina would go into the carbon marketplace to buy some of their credits. Meanwhile, the hog industry in North Carolina emits a lot of greenhouse gases; however, the swine industry is poised in the next five years to begin installing environmentally superior technologies that not only will reduce the impact of the hog industry on water quality issues but also will dramatically cut the amount of greenhouse gas emissions coming from the swine sector.

Mr. Shore said the swine industry has millions of dollars of value in greenhouse gas credits that when there is a carbon marketplace for North Carolina, they will have credits to sell into the carbon marketplace, annually.

Mr. Shore said this is big money and it can help fund the conversion to cleaner technologies in the swine industry.

Mr. Shore that forestry and agriculture, as we grow crops, the trees pull carbon out of the atmosphere and hold it. The forestry and agriculture can get credits for those reductions.

Mr. Shore added that some business and industries, like Dupont and Bank of America, are committed to making reductions beyond requirements. And, the renewable energy industry in North Carolina will also benefit tremendously.

Mr. Shore said that North Carolina not playing in the carbon marketplace, with all of its potential, would be like Michael Jordan with all of his value and potential, choosing not to play basketball.

Mr. Shore said that this is a great opportunity for North Carolina and we not only should be preparing for the inevitability of the United States capping greenhouse emissions, but we should be figuring out ways to move toward this carbon marketplace as soon as possible.

Mr. Shore said that the five suggestions his has for the General Assembly are to put in place a state goal to set itself in the right direction on climate change, provide incentives for early reductions, clean car standards, energy efficiency and renewables, and a stakeholder process.

Mr. Shore concluded with a quote from Thomas Edison, "opportunity is missed by most people because it looks like work."

Senator Kinnaird asked Mr. Shore how the State of North Carolina would join the treaty to reduce greenhouse emissions.

Mr. Shore said that in the United States, this carbon marketplace exists but it is at very small level. Until the federal government caps greenhouse gas emissions, the value of a ton of carbon dioxide is quite small.

Mr. Shore said that in the meantime, there are many things that North Carolina can do to move toward that. One, is to set a goal to align ourselves to the reality that there will be caps on greenhouse gas emissions and the other is to be advocating to the federal government that a cap on greenhouse gas emissions is the right thing to do to protect our environment, public health and to move ourselves forward economically.

Mr. Shore added that that the Governor could be proactive in starting conversations with other states to come together with a plan.

Senator Horton commended Mr. Shore on his presentation and said that he believed that environmental defense was the only way to go in protecting the environment in our state.

Representative Gibson announced that ERC would be served lunch today, provided by the Forestry Association, and that the committee would continue to hear presenters through the lunch period.

Representative Gibson asked members to consider this a regular practice and to also consider whether they would be willing to pay $5.00 or $6.00 for lunch for future meetings.

Senator Albertson said that he would make sure a poll was taken of members to ask if they would be willing to pay for their lunch in the future.

Representative Gibson asked those members and staff who planned to go on the field trip to the coast on 29 November 2004 to let Mr. Givens know. He urged members and staff to attend because the direct effect of what our legislations has done would be visibly shown through the tours that are planned.

Senator Albertson thanked all members for their attendance today and for working through lunch.

Mr. James A. Carter, Assistant Secretary for Operations and Development, Department of Environment and Natural Resources (DENR), gave a status report on the actions taken the Department of Environment and Natural Resources (DENR) in response to flooding in western North Carolina. A copy of Mr. Carter's remarks, verbatim, is listed as **Exhibit K**.

Representative Gibson asked Mr. Carter how much did it cost DENR to respond to flooding in western North Carolina.

Mr. Carter said that for the damaged DENR incurred, the park systems incurred something in the ballpark of $300,000 to $400,000 worth of damage. Forestry estimates their loss at around $1.5 million in damages. The EPA folks who came in and helped with the drum and tanks cleanup received some federal assistance and they spent around $500,000 to $700,000.

Representative LaRoque asked Mr. Carter of the 100 that failed, how many of the Notice of Violations and NODs were issued in fines.

Mr. Carter said that he did not know of any fines that were issued.

Representative Gibson asked for copies of his comments today for distribution to those legislators who were affected by the flooding in western North Carolina.

Robin W. Smith, Assistant Secretary for Policy and Planning, DENR, gave a report on the actions taken by the Department of Environment and Natural Resources (DENR) in response to flooding in western North Carolina.

A copy of a handout giving basic information about the environmental permits required for stream-clearing activities, developed specifically for counties outside the coastal area, is listed as **Exhibit L**.

Ms. Smith said that her office has received a lot of questions about what can be done in terms of clearing debris out of streams. Over the years they have known what to tell the people in the eastern half of the state, but this time around the questions were coming from the western half of the state and the answers are a little different.

Ms. Smith said that in the eastern part of the state and the coastal counties, most often the coastal management program becomes the lead agency to deal with authorizing debris or dredging out material from streams. And in the western part of the state, that responsibility largely falls on the U. S. Army Corps of Engineers.

Ms. Smith said that a description has been put together regarding the permitting requirements and how they work in the western part of the state. The U.S. Army Corps of Engineers needs to be contacted about the need for a federal permit if someone is proposing an activity that involves excavation of sediment or removal of rocks from a streambed, use of equipment that will be operated in a streambed, disturbance of the streambank, or placement of sediment, rocks or other debris in or near surface waters or wetlands.

Ms. Smith said that some of the permits issued by the U. S. Army Corps of Engineers are issued under the Rivers and Harbors Act of 1899, an act that covers dredging activities and obstructions in navigatal waters.

Ms. Smith said that Corps of Engineers also issues permits under Section 404 of the Clean Water Act, which deals with putting fill material in waters and wetlands.

Ms. Smith said that their efforts over the last few weeks have been to get the information out to folks in the counties affected by these storms.

Ms. Smith said that the one exception to that is woody debris, vegetative debris or household appliances that have washed into the streams. Folks can remove those themselves without a permit.

Ms. Smith said that some folks had received notices of violation for failure to get the federal permits. What also goes along with the Corps permits is the need for State Water Quality Certification, and the State DWQ issues that certification.

Ms. Smith said that the State personnel in the Asheville office as well as the Corps personnel have been out meeting with citizens and local government officials to make sure they know what the rules of the road are and what they need to be doing in terms of permits before actually getting in a stream and doing a significant amount of work.

Senator Albertson asked Ms. Smith if she believes we are learning from these events and how to better respond in the future to other events that may occur.

Ms. Smith said that there are still gaps in our communication system. We have experience in the coastal area but this time we found ourselves answering questions in the western part of the state.

Ms. Smith said that we might need to put together a disaster response booklet with basic information about what to do in the aftermath of an event.

Representative Gibson asked Ms. Smith how many notices of violation (NOV) are we talking about during the western flooding event.

Ms. Smith said that she did not have the answer to his question but she said she believed it would be a handful of violations. In some cases it has been both the Corps of Engineers NOV for failure to get a permit and an NOV from Division of Water Quality for failure to get certification.

Representative Gibson asked Ms. Smith for a short description of how DENR interfaces with FEMA and local officials whenever there is disaster.

Ms. Smith said there are ways that we can be prepared to get information out, quickly, and there is some additional work that DENR needs to do to make sure that local government officials and local people are informed about what they should and should not do with regard to permitting.

Ms. Smith said there is about $50 million dollars of federal money that will be available through the Natural Resource Conservation Service (NRCS) for stream clearing activities in North Carolina. These monies require some planning.

Ms. Smith said that one challenge in this situation is to get to people quickly enough to let them know not to do too much too soon. There are things that can be done without a permit and waiting until the federal process comes in would be to their advantage and avoid NOV's.

Representative Gibson asked whose responsibility this would be.

Ms. Smith said that this is still being sorted out. Anytime the federal resources are involved the NRCS likes to send their assistance out directly to local governments. DENR has to get into the loop somewhere to make sure that the permits are needed are issued.

Representative Gibson said he would like to meet with Senator Weinstein and chairs of NER to make sure we do whatever is required to alert folks of what their responsibilities are in case of a catastrophe.

Senator Albertson said he agreed with this idea and said we need to be as prepared as we can to respond to catastrophes.

Mr. James D. Simons, State Geologist and Director, Division of Land Resources, DENR, gave a report on the identification of geologic hazards and lessons learned from flooding in western North Carolina. A copy of two handouts related to Mr. Dorman's presentations are listed as **Exhibit M**.

Mr. Simons said that dam safety also falls into the responsibility of his division and is pleased that given the amount of rainfall they had in that area and the number of high hazards of dams that are potential disasters; there were relatively few emergencies in dam safety. The lesson to be learned there is that we can make things better. The dams that have been repaired and built in modern times are holding well.

Mr. Simons said that unfortunately, we are much farther behind on our geohazards problem, particularly landslides. At least 75 landslides damaged or destroyed 25 homes and caused five fatalities from the Hurricanes Frances and Ivan.

Mr. Simons said that before the storm season came, The Geohazards Program was working with a modest grant from emergency management to inventory and form a database of geohazards in North Carolina, which included landslides.

Mr. Simons said that Exhibit M includes a Fact Sheet on landslide protection. They knew that landslides were going to be a problem with the type of rain that was involved with the Hurricanes Frances and Ivan.

Mr. Simons showed slides from some of the landslides from Hurricane Ivan.

Mr. Simons said there is a certain amount of safety involved before rescuers can enter sites from landslide damage.

Mr. Simons said it was important to have teams in place to respond to the residents. There are only two or three geologists in the Asheville office who could respond.

Mr. Simons said that presentations have been given to river interest groups, answered media inquiry and put into place a database and created a web page.

Mr. Simons said they would like to continue to inventory the spots they have not gotten to, yet, and see what caused them. Unlike lightening, landslides do happen at the same spot again and there are lessons to be learned from studying the spots where there was a failure.

Mr. Simons said that most of the geologists are already committed to other projects. They do have a grant with the Division of Emergency Management that will help them with their work over the next year.

Mr. Simons said that landslides are not the only geohazards in North Carolina. The threat of erosion to the Outer Banks is a hazard. The underlying geology makes certain areas more erodeable.

Mr. Simons said that a problem they see occurring more frequently now is a number of underground gold, copper and silver mines in the Charlotte and Cabarrus County, Monroe and Union County area and land developers who are not aware of these mines.

Mr. Simons said that another problem are sinkholes in the limestone in central and southeastern part of the state. Pumping for agriculture or domestic use wells disturbs ancient voids in the limestone that occurred over millenniums.

Mr. Simons said that he did not believe that we have too much potential for gigantic sinkholes as in Florida but a sinkhole of any size can become a major hazard.

Mr. Simons said that earthquakes are not a great risk but they are out there.

Mr. Simons said that one thing getting more attention now is naturally occurring toxins in the groundwater such as radon and arsenic. More work needs to be done to try to predict where these toxins are located.

Mr. Simons said that in some areas of the state, shrink swell soils are a problem in foundations. We don't have some of the problems like California has but we have hurricanes that California doesn't have.

Mr. Simons said that when we see the blip off of the African coast, we not only have to worry about the Outer Banks but we need to worry about the Gulf and whether it will come up to our mountains.

Mr. Simons said that with the mountain development, as bad as these storms were, historically they were not as bad as the rainfall in 1916-1940, which had fatalities without all of the development. The landslide hazard is out there for a tremendous potential hazard in the future.

Mr. Simons introduced Mr. Rick Wooten, Senior Geologist, North Carolina Geological Survey, who led the efforts on investigating these landslides during the hurricanes.

Representative Gibson asked Mr. Simons what type of landslide or geohazards do we typically see in North Carolina.

Mr. Simons called on Mr. Wooten to answer the question.

Mr. Wooten answered Representative Gibson's question by saying that there is some type of landslide in North Carolina each year. The threshold value looked at in terms of rainfall is about five inches of rain in 24 hours.

This can occur in rainfalls such as hurricanes as well as in summer thunderstorms in the mountains.

Representative Gibson asked if we had somewhere in the neighborhood of 75 landslide or geohazards events as a result of these two storms.

Representative Gibson asked if that is twenty five times more than normal.

Mr. Wooten said that there are about twenty times more landslides during storms like the hurricanes than those seen in a normal year. By inventorying the landslides, they hope to get information on those areas that are more susceptible to slides and get that information to the counties so they can start planning for future events.

Representative Gibson asked Mr. Wooten if the inventorying of these slides had been going on for about ten years.

Mr. Wooten said the inventorying has been done for one year, since receiving funding for this project.

Representative Gibson asked if we had an idea of how many landslides we have had in North Carolina in the past ten years.

Mr. Wooten said we did not have specific numbers but we do have Arial photography from 1940 to look at landslides in Watauga County that occurred from that hurricane.

Mr. Wooten said that he doesn't think we have to have every landslide counted before we start finding out what areas are more susceptible than others.

Representative Gibson said that he is interested in finding out how much of the landslides are caused by manmade conditions and how are we going to find out what we need to do if we don't know where we are on this.

Mr. Wooten said that this is what the Geological Survey is working on. From the data collected so far, they have about 400 data entries of no landslide locations on where old landslide deposits are. They have provided reports to county emergency management folks to give them an idea of locations in their counties where potential problems could occur.

Mr. Wooten said that a lot of what they have seen in the recent storms, the landslides are related to development on steep slopes.

Mr. Simons said that a five inch rain has about a two percent chance of occurring somewhere in North Carolina each year and somewhere in North Carolina will get a 100-year storm.

Representative Gibson asked if in every 100 storms, two of them would be a five-inch event.

Mr. Simons said that it was just a statistical way of saying it was a two percent probability.

Mr. Givens asked Mr. Wooten if there was a program that could map and possibly predict where these events might occur in the future.

Mr. Wooten said that was correct.

Mr. Givens asked if this program has been in place about a year.

Mr. Wooten said they have been using this program for about a year.

Mr. Simons said that this program is a temporary grant with Emergency Management.

Mr. Givens said asked then if it is a grant rather than an appropriation.

Representative Gibson asked if this was a state grant or a federal grant.

Mr. Simons said it was a state grant from Emergency Management.

Representative Gibson asked Mr. Simons how much more money it would take to finish the program.

Mr. Simons said there was not enough money to continue the program and don't know whether the program will be funded again.

Mr. Givens asked Mr. Simons if they were going about this on a county-by-county basis.

Mr. Wooten told me Givens that he thought he was referring to a computer program.

Mr. Givens said that he found out that floodplain mapping was proceeding at the stately pace of one county per year and that it would take 100 years to do them all.

Mr. Givens asked Mr. Simons at what pace they are proceeding with their program and at what pace to they need to proceed.

Mr. Wooten answered the question by saying that this was being done on an "as requested" basis. An example is the Peeks Creek watershed and areas in Watauga County.

Mr. Wooten said that to do an assessment of landslide potential in a given area, they could do it relatively quickly—in a month, by county. This would be a planning level type of assessment, not ground truth, but would be

useful in emergency response and land use planning but not for assigning insurance rates or determining whether you could or could not build in certain areas. The more detailed information needed, the longer it would take. He believed it would take in excess of five years.

Mr. Givens suggested to members that they might want to request of Mr. Simons and Mr. Wooten for an estimated proposal as to what it would take to do this in the same manner as the floodplain mapping and some type of estimate of time and resources to get it done.

Senator Albertson asked Mr. Simons if he would be able to provide this information.

Mr. Simons said that he would be happy to provide this information for ERC and staff.

Senator Kinnaird asked if landslides are something that insurance companies will pay for and/or can such insurance be purchased and if so, is it wise to do so.

Mr. Wooten said that in the case of Peeks Creek, people are having difficulty in getting insurance reimbursements.

Senator Horton said that in the aftermath of Hurricane Floyd, there was some discussion of new floodplain delineation that did not involve the old fashioned technique. Using the new technique, would it still take 100 years to get the job done.

Mr. Simons said that it can be done in much less time with new technology.

Senator Horton asked if we are being held up by lack of funds, like of personnel, or lack of maps.

Mr. Simons told Senator Horton that the holdup is due to all of the things he mentioned.

Mr. Givens told Senator Horton that the next presentation would address floodplain mapping and the question was how to apply that type of program to geologic hazard mapping.

Senator Horton said that our state is too flood prone to not have clear delineations and have them in hand and suggested that we get this information as to what needs to be done as soon as possible.

Mr. John K. Dorman, Director, North Carolina Floodplain Mapping Program, Division of Emergency Management, Department of Crime Control & Public Safety, gave a report on the Floodplain Mapping Program and efforts to expedite the updating of floodplain maps in western North Carolina. A copy of Mr. Dorman's slide presentation is listed as **Exhibit N**.

Mr. Dorman said that the floodplain-mapping program was started following Hurricane Floyd due to a number of issues that arose. Either 80 percent of properties that were either damaged or destroyed during Hurricane Floyd were not depicted accurately in or outside of a floodplain.

Mr. Dorman said that those individuals who were depicted outside the floodplain had not bought flood insurance and therefore had to bear the expense or the state and federal government had to bear the burden.

Mr. Dorman said that the currency of the maps were outdated. The majority of the maps were at least ten years and 75 percent of the maps were over five years old. As development, new roads and changes in topography of the ground changed so did the floodplain.

Mr. Dorman said that $56 million a year was estimated to be cost avoided from flood damage if we had up to date, accurate maps across the State of North Carolina. That is solely because there would be no new development into a risked area that in a 100-year event would be flooded.

Mr. Dorman said that U.S. G. S. estimated that for every dollar spent on flood mapping program and the data collected from that, that data could be used for other purposes other than flood mapping.

Mr. Dorman said that most of the counties and communities, other than Charlotte-Mecklenburg, did not have the resources to update their maps. As Mr. Givens indicated, FEMA had a limited amount of money back in 2000-2001, approximately $50 million dollars a year to do the nation as a whole and they estimated to do one county per year. In that county, it was not studying all of the streams in the county, but rather one or two miles of study. There was a real issue or need for the state to take this over.

Mr. Dorman said that the real issue is when we will get flooded. In 2004, the majority of the western part of the state, from Ivan and Frances, flooded.

Mr. Dorman said that in two years, 95 out of 100 counties had federally declared disasters, the majority of which came from flooding.

Mr. Dorman said that in 2000, the Governor met with the leadership in the General Assembly to come up with three strategies: the first strategy was to develop a state-wide program that would go across the whole State of North Carolina, updating and collecting new elevation data, new engineering studies, building new maps with a new digital component that would allow it to be much more efficiently updated.

Mr. Dorman said that the hand and glove to that strategy was going to FEMA. FEMA did not have the funds or resources to put its attention to North Carolina, so North Carolina became the first state in the nation to become a cooperating, technical state. That basically turned over the responsibility for updating the maps and maintaining the maps to North Carolina.

Mr. Dorman said that there were a number of people who died in Hurricane Floyd by driving across inundated roads. At that time, they were asked to establish a real-time inundation and flood alert component that will be released in February 2005.

Mr. Dorman said that the flood plain mapping program was a phased report, basin by basin.

Representative Hackney asked Mr. Dorman was a real-time alert is for flooding.

Mr. Dorman said that once a stream is studied and know the level of water in the stream, new stream gauges are being placed in strategic locations that go to the USGS satellite every fifteen minutes, which comes back to our system. Based on that stream gauge level at every half foot, we are depicting where that water will be at that time.

Representative Hackney asked Mr. Dorman what would happen next.

Mr. Dorman said that what they would be adding to this would be an alert component. If that gauge had a reading of 9 and one half feet, then an alert would go out to the emergency managers in the community to let them know that it is at alert one.

Senator Kinnaird asked Mr. Dorman why this information would not be aired on television and radio.

Mr. Dorman said that is exactly what they would be doing. They are meeting with the major television stations in the area to coordinate getting this information on a website that they can, in turn, show on TV. At whatever point this information can be provided to this public, it will be shown.

Senator Albertson asked Mr. Dorman that when there is an increase in development, would that change the flood maps over a period of time.

Mr. Dorman said that it would. Impervious surfaces, backfilling with dirt, new roads and bridges would affect the maps.

Mr. Dorman showed an example of one of the new maps, which showed an aerial image of the ground. The maps are derived solely from digital data. Digital base map information is being collected from communities as well as digital elevation data. The engineering studies are being done in a digital model and all of that data is being layered to develop an updated map.

Mr. Dorman said that NASA created a technology back in the late 1960's that allowed an airplane to be flown that gave out pulses of light. As those pulses of light hit the ground and bounce back up, there is a new understanding of what is on the ground. This is what North Carolina has used to collect the elevation data.

Mr. Dorman said that what is done in flood mapping is to remove all of the artifacts off the ground so they know what the bare earth looks like how the water will flow. Then impervious surfaces, development, bridges and anything that can change that flow are added back. This is what is shown on the flood maps.

Mr. Dorman said that there are 42 counties that have flood maps in their hands to make good flood plain mapping decisions. Some of the counties are split between basins, so they are trying to finish those up that are between the Roanoke and Tar Pam basins.

Mr. Dorman said that there are about 18 counties with final floodplain maps. The Cape Fear basin was funded in 2003 by FEMA and they believe the Cape Fear will be completed by March or April 2005. They have collected elevation data for all of Phase II and have received $13 million in funding to do the Catawba and Roanoke basins.

Mr. Dorman said they are waiting on funding for the Yadkin, Chowan, Watauga and New River basins, totaling $19.8 million, which they are asking out of their 2005 budget. Phase III has not been started.

Mr. Dorman said that there are basically 16 counties in the western part of the state with maps that are all over five years old. There are two counties with maps between five and ten years old and six counties with maps that are 11-20 years old. The map scale is pretty course and a much more accurate of scale is needed. There are four counties that have never had flood studies done.

Mr. Dorman said that Macon, Polk, and Rutherford counties have the oldest flood maps.

Mr. Dorman said that if a development comes in, it pushes dirt and causes the floodplain to change; therefore, pushing housing developments into a floodplain.

Senator Albertson asked Mr. Dorman how they plan to keep these maps updated.

Mr. Dorman said that in the State's business plan with FEMA, they are going to take over what is called the maintenance component or letters of map division. With the digital version, they maps can be updated quickly.

Mr. Dorman showed that in the Division of Emergency Management, there is actually mitigation work for homes that have been flooded or want to have prevention from flooding.

Mr. Dorman concluded by saying that in Phase II, they will be collecting some digital orthos. They have the funding for this. The engineering cost is being paid for by FEMA. The State of North Carolina was appropriated $1.2 million in 2002 by the General Assembly for Phase II. They are getting from FEMA about $32 million for Phase II by leveraging what has been done.

Mr. Dorman said that Phase III will be to collect elevation data and the cost for that is right at $5.2 million as well as digital orthos, which will cost right at $250,000.

Mr. Dorman said that if this data is collected, they will be able to leverage from FEMA about $9.8 million to do the engineering and studies.

Representative Gibson asked Mr. Dorman and Mr Carter to share their presentations and information with those members of the General Assembly who were west of I-77.

Representative Gibson asked Mr. Dorman if the League of Municipalities, County Commissioners, Emergency Management folks and engineers were all on the same page.

Mr. Dorman said that North Carolina was the national leader in flood mapping. We have cooperating state committee that has local, county, federal, state, private, building community and the environmental community all on board in providing input and feedback.

Representative Gibson said that the private sector would find this an incredibly valuable tool.

Mr. Dorman said that all of the data can be downloaded, free of charge, that is currently on the website. It is www.ncfloodmaps.com

Representative Gibson asked if the information would be downloadable and manipulative.

Mr. Dorman said that it would be. He said they also have a person solely responsible for providing data requests.

Mr. Dorman said that 40 counties have asked for the elevation data. Counties are collecting their own digital orthos. The elevation provided to those 40 counties saves them between $45,000 and $65,000 on their collection of orthos or a $4.2 million savings to the counties.

Representative Gibson asked their data could be transposed over what is provided to them by the mapping program.

Mr. Dorman answered in the affirmative. He added that in the next two to three months, they would be able to pull other county data on the fly into their county data.

Representative Gibson asked what areas would be mapped next.

Mr. Dorman said that the approach is to do the piedmont area before the western area.

Representative Gibson asked if there was a complication involved when development pressure and number of people causes grief because science doesn't care.

Mr. Dorman said that it was not causing complication because different levels of impervious surface are based on population, soil conditions which the model allows.

Mr. Dorman said that they meet with county municipalities upfront before any work is begun to find out which streams need to be studied.

Mr. Dorman said that they have not had any counties who refused to adopt these maps.

Representative Gibson asked if the piedmont was being done next based on population and impervious surfaces and asked would it not take twice as long to do the piedmont before the western part of the state.

Mr. Dorman said that the piedmont should go much quicker than the eastern maps took. They studied in Phase I over 12,000 stream miles and Phase II will be close to 13,200 stream miles.

Senator Albertson asked Mr. Dorman how we can be assured that this information is correct.

Mr. Dorman said that certified engineers do the model. The State's engineers review the data and FEMA has a set of engineers that look at the data. When it goes to the community, there is a 90-day appeal period. So, there are four reviews to make sure the data is accurate.

Representative Gibson asked Mr. Dorman what is the rate for quality control.

Mr. Dorman said that FEMA has standards that have to be met and the state is exceeding those standards.

Mr. Dorman said that every county is responsible for doing a mitigation plan. In that plan are a lot of different hazards that communities need to deal with and the one in the western part of the state will be landslides and flooding.

Representative Gibson asked when these mitigation plans are due.

Mr. Dorman said they were due in November.

Representative Gibson asked if all of these mitigation plans were in.

Senator Kinnaird said that in the discussions yesterday regarding the fishing license and the proposal that it not be due until 2007, she hoped that we would go to the mid-July point of 2006 instead. She said she would like this to be the goal.

Senator Kinnaird brought up the method of distribution of handouts. She asked if the handouts could be distributed by request only.

Representative Gibson said that all handouts are recycled or returned to the Departments who distribute them.

Representative Gibson said that it was clear to him on the fishing license issue at yesterday's meeting that we have the makings of a workable solution and urged ERC members to have fisheries and wildlife get together before our next to the last meeting in January 2005, and come up with a chronology and possible solution to the license issue as well as a timeline.

Senator Albertson said that the challenge for us was to come up with what it is we want them to do so they can move ahead with the process.

The meeting was adjourned at 1:50 p.m.

Representative Daniel McComas Presiding Co-Chair	Mary R. Watson Commission Clerk

RE: **Notice of November Commission Meetings**
Notice of Planning Meeting
Coastal Site Visits
Schedule of Future Meetings
Meetings of Interested Parties (605 Working Groups)
Additional Information

COMMISSION MEETING:

The Environmental Review Commission (ERC) will meet jointly with the Joint Legislative Commission on Seafood and Aquaculture (JLCSA) at 11:00 a.m. Thursday 18 November 2004 in Room 544 of the Legislative Office Building in Raleigh. The meeting will focus on the development and implementation of the Coastal Habitat Protection Plan pursuant to G.S. 143B-279.8 and a discussion of issues regarding the implementation of the coastal recreational fishing license established by S.L. 2004-187 (Saltwater Fishing Fund). **We anticipate that the meeting will last until late afternoon. Boxed lunches will be provided for members of the ERC and JLCSA.**

The ERC will meet for its regular monthly business meeting at 9:30 a.m. Friday 19 November 2004 in Room 544 of the Legislative Office Building in Raleigh. At this meeting, the ERC will begin or continue studies for which the ERC is responsible, hear reports from State agencies, discuss topics to be considered at future meetings, and attend to other matters. Listed below are potential agenda topics for this meeting and for future meetings. More specific information regarding the agenda for the 19 November meeting of the ERC will be developed at the staff planning meeting discussed below. **We anticipate that the meeting will last until early to mid afternoon. Boxed lunches will be provided for members of the ERC.**

STUDY TOPICS:

Air Quality:

1) Modification of the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle (S.L. 2004-161, Sec. 19.10(1))

2) Modification of the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle (S.L. 2004-161, Sec. 19.10(2))

3) Issues related to greenhouse gas emissions and global climate change

Miscellaneous:

4) Effectiveness of the State's efforts to protect the environment and conserve the natural resources of NC (S.L. 2004-161, sec. 19.2)

5) Development of a plan to share floodplain mapping information (S.L. 2004-161, Sec. 19.3)

6) Efforts to stimulate renewable energy production in the State

7) Results of the conservation needs assessment conducted by the Land for Tomorrow Coalition

Water Quality:

8) Approaches to prevent and reduce stormwater pollution throughout the State (S.L. 2004-161, Sec. 19.11)

9) Issues related to the Leaking Petroleum Underground Storage Tank (UST) Cleanup Program (S.L. 2003-352, Sec. 12)

10) The role of the State and DENR in implementing the Leaking UST Cleanup Program (S.L. 2004-124, Sec. 30.10.(f)) (joint study with the Joint Legislative Transportation Oversight Committee)

11) Identification and closure of inactive or abandoned animal waste management lagoons

Water Quantity:

12) Water restriction guidelines created by DENR and implemented by local governments, including an evaluation of economic impacts and recommendations for establishing consistency across the State with respect to classes of water use (S.L. 2004-161, Sec. 19.4)

13) Development and funding of regional water supply systems (S.L. 2004-161, Sec. 19.5)

14) Water conservation measures being implemented in the State and incentive programs and other voluntary programs that can help foster water conservation and reuse

15) Expansion of the guaranteed energy savings contracts program for governmental units to include contracts that provide for the conservation of water and sewer usage

REPORT TOPICS:

Air Quality:

16) Annual report on the cost of the Title V Program (G.S. 143-215.3A(c)

17) Annual report on implementation of S.L. 2002-4 (Clean Smokestacks Act) (S.L. 2002-4, Sec. 14)

18) Annual report on issues related to the development and implementation of standards and plans to implement programs to control emissions of mercury and carbon dioxide from coal-fired generating units and other stationary sources of air pollution (S.L. 2002-4, Sec. 12-13)

19) Annual report on increasing the use of alternative-fueled and low-emissions light-duty cars and trucks in privately owned fleets (G.S. 143-215.107C(c))

20) Annual report on development and implementation of a plan to reduce vehicle miles traveled by private sector employees and vehicle emissions resulting from job-related travel, including commuting to and from work (G.S. 143-215.107C(e))

21) Annual report on development and implementation of a plan to reduce vehicle miles traveled by State employees and vehicle emissions resulting from job-related travel, including commuting to and from work (S.L. 1999-328(4.6))

22) Annual report on promotion of telework/telecommuting for State employees and achieving the goal of reducing State employee vehicle miles traveled in commuting by 20% without reducing total work hours or productivity (S.L. 1999-328(4.8))

23) Report on the evaluation and adjustment of the boundaries of the area served by each Metropolitan Planning Organization (G.S. 136-202(d))

Parks and Recreation / Land Conservation:

24) Parks and Recreation Trust Fund Annual Report, Fiscal Year 2003-2004 (G.S. 113-44.15(c))

25) North Carolina Natural Heritage Trust Fund Award Report, Fiscal Year 2003-2004 (G.S. 113-77.9(e))

26) Annual report on progress towards attaining the State's goal of protecting one million acres of farmland, open space, and conservation lands (G.S. 113A-241(c))

27) Annual report on implementation of the Conservation Easements Program and inventory of all conservation easements held by DENR (G.S. 113A-235(c))

Water Quality:

28) Annual report on the Wastewater Discharge Elimination Program (S.L. 2001-452, Sec. 2.9)

Water Quantity:

29) Annual report on the progress of water supply planning (G.S. 143-355(n))

Wetlands:

30) Implementation of the Wetlands Restoration Program and use of funds in the Wetlands Restoration Fund (G.S. 143-214.13)

PLANNING MEETING:

To facilitate development of the agenda for the 19 November meeting of the ERC, to plan for subsequent meetings of the ERC, and to receive input from interested persons regarding the work of the ERC, the Commission Counsel will hold an informal planning meeting at **10:00 a.m. on Tuesday 9 November 2004 in Room 605 of the Legislative Office Building**. Persons who wish to participate in the development of the agenda for meetings of the ERC, or who are interested in any matter before the ERC, are invited to attend.

COASTAL SITE VISITS:

Members and staff of the ERC and JLCSA will visit several coastal sites in the Atlantic Beach/Morehead City/Beaufort area related to marine fisheries beginning at 9:00 a.m. on Monday 29 November 2004. These site visits will be similar to those originally scheduled for 27 September 2004 but were subsequently canceled because of Hurricane Jeanne. No business meeting will be held in conjunction with the 29 November 2004 site visits. Members should, however, plan to arrive in Atlantic Beach by 5:00 p.m. Sunday 28 November 2004 if possible. Further information on the site visits, including information on accommodations, will be sent to members of the ERC and the JLCSA in the next week.

SCHEDULE OF FUTURE MEETINGS:

The ERC will not meet on 22, 23, or 30 November, so it is no longer necessary to ask that you reserve these dates. Below is a schedule of meetings of the ERC for December 2004 through January 2005. This schedule is tentative and subject to adjustment. For planning purposes, please reserve these dates.

Commission Meeting	Staff Planning Meeting
Tuesday 7 December 2004	Wednesday 1 December 2004
Wednesday 12 January 2005	Wednesday 5 January 2005
Thursday 13 January 2005	
Thursday 20 January 2005	
Tuesday 25 January 2005	

MEETINGS OF INTERESTED PARTIES (605 WORKING GROUPS):

The Commission Counsel will hold meetings of interested parties on specific topics as indicated below:

Limit Liability for Environmental Cleanups Working Group (HB 1603/SB 1222)
10:00 a.m. Thursday 2 December 2004 – 605 Legislative Office Building

ADDITIONAL INFORMATION:

If you have questions related to the Commission, please feel free to contact the Commission Counsel or other Commission staff at (919) 733-2578.

MEMORANDUM

To: Members of the Environmental Review Commission
From: Tim Dodge, Research Assistant for Environmental Issues
Re: Reports to the Commission

This memorandum lists reports that have been submitted to the Environmental Review Commission by State agencies, as required by law, since the last reports distribution on 21 October 2004.

A. REPORTS RELATED TO TODAY'S AGENDA

The following reports are attached to this memorandum. These reports may be referenced during the course of the 19 November 2004 Commission meeting.

Environmental Health (Agenda item 4):

1. *Annual Report on the Wastewater Discharge Elimination Program.* Department of Environment and Natural Resources (DENR). 16 November 2004. Statutory Authority: S.L. 2001-452, Sec. 2.9.

Water Quantity (Agenda item 5):

2. *Annual report on the progress of water supply planning.* Division of Water Resources, DENR. 17 November 2004. Statutory Authority: G.S. 143-355(n).

Air Quality (Agenda item 6):

3. *Annual report on the cost of the Title V Program.* Division of Air Quality, DENR. 18 November 2004. Statutory Authority: G.S. 143-215.3A(c).

4. *Annual report on implementation of S.L. 2002-4 (Clean Smokestacks Act).* DENR and the North Carolina Utilities Commission. 1 June 2004. Statutory Authority: S.L. 2002-4, Sec. 14.

5. *Annual report on issues related to the development and implementation of standards and plans to implement programs to control emissions of mercury from coal-fired generating units and other stationary sources of air pollution.* Division of Air Quality, DENR. 1 September 2004. Statutory Authority: S.L. 2002-4, Sec. 12.

6. *Annual report on issues related to the development and implementation of standards and plans to implement programs to control emissions of carbon dioxide from coal-fired generating units and other stationary sources of air pollution.* Division of Air Quality, DENR. 1 September 2004. Statutory Authority: S.L. 2002-4, Sec. 13.

7. *Annual report on increasing the use of alternative-fueled and low-emissions light-duty cars and trucks in privately owned fleets.* DENR. 1 September 2004. Statutory Authority: G.S. 143-215.107C(c).

8. *Report on the evaluation and adjustment of the boundaries of the area served by each Metropolitan Planning Organization.* Department of Transportation. 1 November 2004. Statutory Authority: G.S. 136-202(d).

B. REPORTS HELD FOR FUTURE PRESENTATIONS

The following reports are being held for distribution in conjunction with a potential agenda item at a future meeting of the Commission.

Parks and Recreation / Land Conservation:

9. *Parks and Recreation Trust Fund Annual Report, Fiscal Year 2002-2003.* Division of Parks and Recreation, DENR. 1 October 2004. Statutory Authority: G.S. 113-44.15(c).

10. *North Carolina Natural Heritage Trust Fund Award Report, Fiscal Year 2002-2003.* Division of Parks and Recreation, DENR. 1 October 2004. Statutory Authority: G.S. 113-77.9(e).

11. *Annual report on progress towards attaining the State's goal of protecting one million acres of farmland, open space, and conservation lands.* DENR. 1 October 2004. Statutory Authority: G.S. 113A-241(c).

C. OTHER REPORTS

The following report was discussed during oral presentations at the 21 October 2004 Commission meeting, but a written copy was not distributed at that time:

Water Quality:

12. *Annual report on the compliance/ enforcement of water quality laws for facilities that discharge into surface waters.* DENR. 1 October 2004. Statutory Authority: G.S. 143-215.9A.

The following report was distributed to members of the Environmental Review Commission at its joint meeting with the Joint Legislative Commission on Seafood and Aquaculture on 18 November 2004.

General:

13. *Annual report on progress in developing and implementing Coastal Habitat Protection Plans.* DENR. 1 September 2004. Statutory Authority: G.S. 143B-279.8(e).

Please contact George Givens, Jeff Hudson, Jennifer McGinnis, or Tim Dodge at (919) 733-2578 if you have any questions or comments.

One NorthCarolina Naturally

NC Wastewater Discharge Elimination Program

2004 Annual Report to the North Carolina General Assembly

November 2004

North Carolina Department of Environment and Natural Resources
Division of Environmental Health
On-site Wastewater Section

N.C. Wastewater Discharge Elimination Program
2004 Report

The North Carolina Wastewater Discharge Elimination (WaDE) Program is located in the On-site Wastewater Section of DENR's Division of Environmental Health. The WaDE Program was established pursuant to S.L. 1996-18es2, Section 27.26, to identify and eliminate discharges from straight pipes and failing septic systems to land surfaces and streams. Funds appropriated by the N.C. General Assembly support a two-member team to address the straight pipe and failing septic system issues in North Carolina. Additional financial support has been secured through grants from the N.C. Clean Water Management Trust Fund (CWMTF) and the U.S. Environmental Protection Agency (EPA) 319 Non-point Source Program. Strong collaboration with local and federal agencies as well as the public, the media, and environmental groups is the hallmark of the WaDE program and the key to its successes thus far.

Program Goals

The primary goal of the WaDE Program is to identify and correct violations of on-site wastewater systems in western North Carolina, ultimately eliminating domestic sewage discharges into streams and other water systems. Based in Asheville and serving 26 western North Carolina counties, the WaDE Program works with local health departments to identify straight piping and keep sewage out of streams that are used as public water supplies (see attachment 'Public Water Supply Surface Intake Points of NC'). The program also identifies, and at times channels, sources of financial assistance for low-income homeowners in need of septic system repairs. This financial assistance is usually in the form of grants and loans, which are distributed through regional councils of government or non-profit housing rehabilitation agencies. The WaDE Program also provides public health and environmental education to homeowners and other stakeholders at the community, county, regional, state, and federal levels related to on-site wastewater issues. In addition, to meet the statewide demand for septic system repair and straight pipe elimination, the WaDE Program is currently collaborating with the University of North Carolina's Environmental Finance Center to develop a statewide model for a septic repair financial assistance program.

Previous Accomplishments

During the first four years of the program, the WaDE team directed one survey project (Buncombe County) and assisted in four other independent county surveys funded by the CWMTF, N.C. Department of Commerce's Division of Community Assistance (DCA), Appalachian Regional Commission, and N.C. Rural Communities Assistance Project (RCAP). The counties targeted in the independent surveys were Alleghany/Ashe, Jackson, Madison, and Avery/Mitchell/Yancey. The WaDE Program's 1998 independent survey of the Ivy Watershed in Buncombe County received a small amount of funding from RCAP; its results are included in the Expanded WaDE Program section below.

Participating local health departments tracked survey-related corrections; however, many are no longer tracking corrections due to loss of funding support. As of the last report, approximately 19,150 homes were surveyed during these independent efforts, and violations were found at 2,505 (13%) of these homes. As of 2003, 1,244 (50%) of those violations had been corrected, with 480 (39%) violations being corrected with financial assistance. At the minimum rate of 240 gallons of

wastewater per household per day, this represents 298,560 gallons of untreated wastewater removed from the streams daily.

The Expanded WaDE Program

In 2001, the WaDE team proposed a new model for achieving the goals of the program, and this model was approved and funded for three years by the CWMTF ($1.2 million over three years) and the EPA 319 Non-point Source Program ($500,000 over three years). Since the expansion in 2001, the WaDE program has added seven full-time and two temporary team members (surveyors) to the original two-person staff.

The WaDE surveyors provide support to county environmental health specialists with already-full workloads who have the responsibility for issuing septic system repair permits and inspecting the repaired work for homes identified as needing improvements by the WaDE surveys. In addition, WaDE surveyors assist homeowners who self-report problems with their on-site wastewater systems, giving homeowners substantial time to resolve the problem. In this capacity as DENR employees, surveyors also provide amnesty considerations to homeowners who cooperate with the field surveys, as these homeowners are considered to be self-reporting. In the past 21 months, WaDE team members have surveyed 4,707 homes and identified 725 violations (15% violation rate) in nine counties. About 229 repairs have been completed; 143 of them with financial assistance (see second attachment for additional survey statistics).

As part of the expanded model, the WaDE Program provides financial assistance for septic system repairs in 19 counties in western North Carolina. Financial assistance is being provided through collaboration with CWMTF, DCA, U.S. Department of Agriculture's Rural Development Program, and regional councils of government that have experience with similar housing rehabilitation programs. In addition, the WaDE Program works to annually identify changing sources of financial assistance for septic repairs in all North Carolina counties.

The WaDE Program also provides public education on various public health concerns and environmental issues. This information is offered to the public through such mechanisms as public service announcements, public community meetings in survey areas, door-to-door visits by trained WaDE surveyors, teachers' guides and videos for school children, outreach to the N.C. Real Estate Commission on property disclosure requirements, and other various publications, slide shows, and talks geared toward local, state, and national audiences. The program has also received positive attention from the local media, which aids in informing the public and encouraging owners of failing systems and straight pipes outside of survey areas to come forward for assistance.

Future Directions

The WaDE Program is performing well within its mandate and scope, however, addressing several challenges would enable this program to reach its full potential in assisting residents of the state.

- *Human capacity*. While the WaDE Program has developed strong relationships with the local health departments serving the 26 counties in which it works, as well as with state and federal funding agencies, the current staff cannot identify and assist in the repair of all failing septic systems in those counties.

- *Geographical scope.* The WaDE Program currently serves 26 western counties in North Carolina. However, the impacts of straight pipes and failing septic systems are not limited to these counties. Failing septic systems present a threat to public health and to the environmental quality of North Carolina's waterways in communities across the state.

- *Financial resources available for repair/replacement.* A large number of systems in need of repair or replacement are identified during each door-to-door survey. Many of these systems belong to people with limited financial resources who are unable to pay for system repairs even when the local health departments waive the repair permit fees. Sources of financial assistance are critical for these systems. The WaDE Program has secured temporary funding for financial assistance. A permanent mechanism for identifying, providing and distributing grants and low-interest loans to eligible homeowners in need of septic repair across the state would enable the removal of more untreated waste from North Carolina's streams and rivers and provide safer and healthier wastewater treatment options for many residents beyond the timeframe of the current funding. This establishment could work with local governments, regional councils of governments, and local housing rehabilitation agencies to identify potential sources of financial assistance.

One NorthCarolina Naturally

Department of Environment and Natural Resources

Division of Water Resources

STATUS REPORT TO THE GENERAL ASSEMBLY ON WATER SUPPLY PLANNING SEPTEMBER 1, 2003 THROUGH AUGUST 31, 2004

Assuring a sustainable future water supply for North Carolina is the primary mission of the Division of Water Resources. To carry out this responsibility, the division administers several monitoring, planning and regulatory programs.

The division, in partnership with the U.S. Geological Survey, monitors the availability of water through a network of monitoring wells and stream gages. DWR assists community water systems with the preparation of Local Water Supply Plans and prepares the North Carolina Water Supply Plan. The division receives and maintains the registrations of large water withdrawals and issues permits for water withdrawals in designated capacity use areas. DWR handles applications for certification of interbasin transfers of surface water and is the lead agency for the Department of Environment and Natural Resources in the relicensing of hydropower projects. This status report provides an update on these water supply programs and on other related division activities.

Water Quantity Monitoring

The division maintains ground water and surface water monitoring networks partly in partnership with federal agencies. The data from these networks provide essential information on the conditions of water resources throughout the state. North Carolina cooperates with the U.S. Geological Survey (USGS) to maintain monitoring sites with near-real time data collection capabilities. The division also maintains a network of ground water monitoring wells. Data from these wells are collected quarterly. About forty percent of these wells have data recorders that provide daily water level data. To improve the accessibility and usefulness of this data for water resource management, the DWR has recently joined with the State Climate Office at N.C. State University, the U.S. Army Corps of Engineers, USGS and others to develop a uniform database to store and disseminate water resources data.

In recent years, with the support of the General Assembly, the DWR has expanded the monitoring well network in the Coastal Plain region, an area where ground water resources are being stressed by over-pumping. Four new monitoring stations with eighteen wells have added critical data to improve management of the regional aquifer systems. The division will expand the monitoring well network as funds permit to reduce the gaps in ground water data.

Changes to the funding formula for the monitoring stations operated cooperatively with USGS have resulted in the discontinuance of data collection at some monitoring sites. Maintenance of near-real time data reporting in the system will require upgrading existing equipment in the near future.

Local Water Supply Plans

The General Assembly established a water supply planning program under General Statutes 143-355(l) and (m) to assure the availability of adequate supplies of good quality water to protect the public health and to support desirable economic growth. The original statute required units of local government that provide or plan to provide public water service to prepare a Local Water Supply Plan (LWSP). During the 2003 legislative session, the General Assembly expanded the scope of water systems required to prepare a LWSP to include community water systems that regularly serve 1,000 or more service connections or 3,000 or more individuals.

LWSPs describe current and future water needs, and assess the system's ability to meet those supply needs. LWSPs must be adopted by the water system's local governing board and be updated at least every five years. The Division of Water Resources is responsible for reviewing the local plans for completeness and consistency.

The plans provide a valuable source of data for all local and regional water supply planning. Information from the local plans is available on the division's Web site www.ncwater.org. In the current update cycle, local government water systems were asked to update their local plans to reflect system conditions and water use during 2002 and to submit the plans to the division by July 31, 2003. The newly-added community water systems were required to submit plans by January 1, 2004. Division staff members expect to receive updated or new plans from about 585 water systems. A list of the 61 water systems not submitting 2002 local plans as of November 17, 2004 is included at the end of this document.

Session Law 2003-387, which expanded the scope of water systems required to prepare a LWSP, also added the requirement that water systems include a description of how they will respond to water shortage emergencies and continue to meet essential public water supply needs as part of their local plan. DWR staff members provide assistance with developing these water shortage response plans.

North Carolina Water Supply Plan

The division uses the information from the LWSPs and other sources to develop the North Carolina Water Supply Plan (NCWSP), mandated by G.S. 143-355(m). The NCWSP presents a summary of water use by major river basin and identifies areas of concern where water availability or conflicts between users may limit the ability to meet water demand.

The 2001 NCWSP is available on the division's Web site at www.ncwater.org. The plan is based on information from the 1992 and 1997 LWSPs and 1999 water withdrawal registrations submitted pursuant to General Statute 143-215.22H. No changes were made to this document during the period covered by this report. The NCWSP will be updated to reflect information in the 2002 Local Water Supply Plans and the results of the River Basin Water Supply Plans discussed in the next section.

River Basin Water Supply Plans

To further the legislative goal of assuring the availability of adequate supplies of water, the Division of Water Resources is developing a River Basin Water Supply Plan for each of the major river basins in the state. The River Basin Water Supply Plans will provide a basin analysis of long-range cumulative water supply demands. By projecting

water needs to 2050 and evaluating these future demands with a hydrologic model, the plans will give local governments and other water users a reliable, quantitative framework within which to plan for sustainable and cost-effective water sources for future needs.

While data from the LWSPs can be used to estimate future water demands and wastewater discharges, analysis of the impacts on a river basin depends on the ability to determine the effects of withdrawals and discharges on river flows. This analysis is performed by using a computer-based hydrologic model that can simulate water movement in the river system. The division prepared a Cape Fear River Basin Water Supply Plan in 2002 in conjunction with analysis of allocations of water supply storage in B. Everett Jordan Lake. The hydrologic model used in that case was developed to analyze the potential impacts of the movement of water between the Cape Fear River system and the neighboring basins. This Cape Fear plan became the model for the river basin water supply planning initiative.

DWR is currently developing River Basin Water Supply Plans for the Catawba and Yadkin river basins. Hydrologic models for these basins are currently under construction in conjunction with the relicensing of the hydropower projects on these rivers. Long-term water supply needs will be documented for inclusion in the new licenses to be issued by the Federal Energy Regulatory Commission. The next priorities for river basin plans will be the Neuse and Tar basins, followed by the remaining North Carolina basins.

Drought Response

Session Law 2003-387 (House Bill 1062) gave the Department of Environment and Natural Resources the authority to establish a Drought Management Advisory Council (DMAC) to improve coordination, management and mitigation of the harmful effects of drought. The DMAC was given the responsibility to issue drought advisories to assist local governments and other water users in taking appropriate actions to address the impacts of reduced water availability.

Division of Water Resources staff members are working with other resource management and data collection agencies to develop a methodology to evaluate the severity of drought conditions in North Carolina. The resulting tool will provide an objective measure of drought severity. The Web-based tool will allow water managers and local decision makers to stay informed of conditions in their particular region of the state and take timely actions to reduce the harmful effects of drought. The DMAC will issue drought advisories to help water users respond appropriately to drought-induced water shortages.

Session Law 2002-167 (House Bill 1215) required the department to conduct an analysis of water conservation measures and possible incentives and voluntary programs that could encourage water conservation and water reuse. A report summarizing the findings of this analysis is available on the DWR Web site at www.ncwater.org under the "Water Conservation" link. The division has invited further public comment on this report and will revise and reissue it by the end of 2004.

The statute also requires the Environmental Management Commission (EMC) to develop administrative rules establishing minimum standards and practices for water use during drought and water emergencies. DWR is coordinating the effort to develop these rules. Several meetings have been held with interested parties to get input on important issues that need to be addressed in any proposed rules. Division staff will continue to meet

with interested stakeholders and members of the EMC to develop a draft rule to go to public hearing. The EMC has to adopt permanent rules that will become effective following legislative review by the 2006 session of the General Assembly.

Central Coastal Plain Capacity Use Area

Rules designating the Central Coastal Plain Capacity Use Area and establishing a water withdrawal permitting system became effective August 1, 2002. The rules were designed to gradually reduce withdrawals from the endangered Black Creek and Upper Cape Fear aquifers in the designated counties. The rules require stepped reductions in withdrawals from the endangered aquifers and encourage the development of alternative sustainable sources of water. Anyone wishing to withdraw more than 100,000 gallons of ground water a day must apply for and receive a permit from the Division of Water Resources. As of November 17, 2004, 109 water withdrawal permits have been issued or renewed resulting in a total of 153 permitted users and 38 permit applications were under review.

Water withdrawers have not made significant reductions in water use from the impacted aquifers to date. The rules provide an initial six-year period for systems to develop plans to adjust water withdrawals and develop alternative sources. Water systems have made substantial progress in identifying new sustainable water sources. Several are pursuing surface water options and some are developing wells to withdraw water from other aquifers. Additional information on the Central Coastal Plain Capacity Use Area and the associated rules can be found on the division's Web site at www.ncwater.org.

Bladen County Capacity Use Investigation

In December 2002, the Water Allocation Committee of the EMC asked DWR to conduct a capacity use investigation of the Southern Coastal Plain area surrounding Bladen County. The study determined that there are areas in the region where water levels are declining due to overpumping of ground water. In some areas, water levels have recovered when pumping was reduced. Other areas show steady water level declines. The monitoring well network in this region is sparse and new wells need to be added to effectively monitor the impacted areas. Water users in the region are taking actions to reduce the impacts on regional ground water resources. The division did not recommend declaring a Capacity Use Area at this time, but supported the formation of an agreement between DWR and local stakeholders and the EMC to expand ground water monitoring and protection efforts. The Water Allocation Committee and the EMC approved this agreement in October 2004. The Southern Coastal Plain Capacity Use Investigation report is available on the division's Web site at www.ncwater.org.

Interbasin Transfer Certifications

Surface water users that wish to transfer more than two million gallons of water in any one day from one river basin to another must apply to the EMC for an Interbasin Transfer Certificate. Users that had an interbasin transfer prior to July 1993 are permitted to continue but must apply for certification before making significant increases. The EMC has to look at the impacts on the source basin and the receiving basin and weigh the benefits against the detriments of the transfer. The process involves extensive

environmental analysis and numerous opportunities for public input and comment. Since the last status report, the following interbasin transfer-related activities have been undertaken.

Concord and Kannapolis are jointly conducting an environmental analysis to support a potential request for an Interbasin Transfer Certificate to transfer water from the Catawba and the Yadkin basins to the Rocky River Basin.

In early 2004, the Kerr Lake Regional Water System began the process to increase their grandfathered transfer of water from the Roanoke to the Tar and Neuse river basins to accommodate the expansion of their water treatment plant from 10 to 20 million gallons per day.

Hydropower Facility Relicensing

The Federal Energy Regulatory Commission (FERC) licenses non-federal hydroelectric generation projects on navigable waterways. The licenses, issued for 30 to 50 years, govern how the hydroelectric projects are managed and therefore how the rivers on which they are located are affected. Upon expiration of an existing license, the licensee has to apply for a new license in order to continue operating the project. Five years prior to the expiration date of an existing license, the licensee has to file a Notice of Intent to apply for a new license. The license application is filed 24 months before the expiration of the existing license. The three years between filing the Notice of Intent and the license application are used to compile the data needed to evaluate the impacts of a project on regional resources and to support the application and requested provisions of the new license.

There are 26 FERC licensed projects in North Carolina. Fourteen of the projects have licenses that expire between 2015 and 2047 and nine have filed license applications that are being reviewed and awaiting decisions by FERC. The remaining three projects, which include most of the major reservoirs in the North Carolina Piedmont, have licenses that expire in 2008. The licensees are currently conducting technical studies and gathering data to support the license applications. These projects are in the Catawba and Yadkin-Pee Dee river basins in North Carolina. Duke Power, a Duke Energy Company, operates the Catawba-Wateree Hydro Project, consisting of 11 reservoirs and 13 hydropower generation facilities in North Carolina and South Carolina. Alcoa Power Generating Inc. – Yadkin Division operates the Yadkin Project, comprised of four reservoirs and hydropower generation facilities on the Yadkin River in North Carolina. Progress Energy Carolinas, Inc. operates the Yadkin-Pee Dee River Project, with two reservoirs and hydropower generation facilities on the Pee Dee River in North Carolina downstream of Alcoa Power Generating Inc. – Yadkin Division's project.

DWR is working closely with the licensees to ensure that water supply issues are given due consideration in the relicensing process. The division is developing river basin water supply plans for the Catawba-Wateree and Yadkin-Pee Dee river basins in conjunction with the relicensing process. In the Catawba-Wateree River Basin the licensee is funding an independent study to estimate water supply use in both North Carolina and South Carolina through 2058. The division is working closely with this project.

To update the information on the other projects discussed in last year's status report, licenses for Duke Power's Nantahala Area projects and Alcoa Power Generating, Inc.'s Tapoco Division projects are still under review by the FERC. Dominion Energy's Lake Gaston /Roanoke Rapids project is expected to be issued a license in the near future.

DIVISION OF AIR QUALITY

DEPARTMENT OF ENVIRONMENT AND NATURAL RESOURCES

EXECUTIVE SUMMARY

The Clean Air Act Amendments of 1970, reviewed and amended by Congress in 1977 and 1990 formed the basis of the federal air pollution control currently in place. Health-based national ambient air quality standards are the strategic basis of the Clean Air Act. The standards were to be met through the application of control technology that would reduce emissions continuously and result in improved air quality. Costs of technological capability were to be subordinated to public health protection requirements. Also, all requirements were to be national, with no facility having a competitive edge by having to meet less stringent controls. The Environmental Protection Agency (EPA) is responsible for carrying out the program.

Prior to the 1990 Clean Air Amendments, EPA set two kinds of National Ambient Air Quality Standards (NAAQS) specifying maximum acceptable levels of pollutants for outdoor air. Primary standards set limits that protect human health; secondary standards provide welfare protection (i.e. plants, animals, aesthetics and materials). EPA set primary and secondary standards for six criteria pollutants: carbon monoxide, nitrogen dioxide, lead, sulfur dioxide, ozone and particulates. Eight substances were listed as hazardous air pollutants: asbestos, beryllium, mercury, vinyl chloride, radionuclides, inorganic arsenic, benzene, and coke oven emissions. National Emissions Standards for Hazardous Pollutants (NESHAPS) were promulgated for sources of seven of these pollutants.

Most air pollution comes from either stationary sources, such as factories, power plants and smelters, or mobile sources such as cars, trucks and airplanes. To limit mobile source pollution, controls were established for automobile emissions. EPA also set standards that applied to new industrial plants and existing ones that were substantially modified. Additionally, state governments were required to draw up State Implementation Plans (SIP's) that set out other measures to achieve acceptable air quality.

Congress mandated the Title V Permit Program, primarily for regulating major air pollution sources, under the Federal Clean Air Act Amendments of 1990. The North Carolina Environmental Management Commission (EMC) established the state Title V Permit Program in 1994 in accordance with state and federal laws and with guidance from the N.C. Clean Air Act Advisory Council. The state Division of Air Quality (DAQ) carries out the program, which received interim approval from the U.S. Environmental Protection Agency (EPA) on December 15, 1995 and final approval in October 2001. To date, the DAQ has issued 402 Title V permits. The Division has one remaining application under review and expects to issue this remaining initial Title V permit by the end of the year.

The Clean Air Act requires that permit fees cover the entire cost of the Title V Program. In North Carolina, the revenue raised from Title V permit fees is close to the estimated cost of the program. This is true even though the total fees collected are only about 78 percent of the minimum fees presumed necessary to run the program under the Federal

Clean Air Act. Many other states charge the minimum presumptive fee, which is $25 per ton in 1990 dollars. The permanent staff size for carrying out North Carolina's Title V program is considered adequate, given the current number of permit applications, the known program requirements, and the DAQ's experience with the program. Contract personnel were, until December 2002, used to assist in the completion of the work on the initial round of permit applications. Now that the initial TitleV permits have been issued, reconsideration of the staffing needs for Title V modifications and renewals will be conducted.

The following additional points are provided to clarify/highlight the information provided in this report:

- The issuance of permits is progressing in a satisfactory manner.
- The division has been able to run a fiscally sound program collecting less in fees than was authorized by the oversight committee at the start of the program.
- The break down of staff between the central office and the regional offices has adequately covered the needs of the division to date. This distribution of staffing is being reviewed since issuance of the initial Title V Permits is nearing completion.

INTRODUCTION

This Accountability Report describes the Title V Permit Program in North Carolina as carried out by the Division of Air Quality, Department of Environment and Natural Resources. The report focuses on funding and staffing issues. It does not cover Title V permit programs under the jurisdiction of local air pollution control programs in Buncombe, Forsyth, and Mecklenburg counties.

Congress established the Title V Permit Program under the Federal Clean Air Act (1990 Amendments), primarily as a way to regulate major air pollution sources. Under the Clean Air Act, Title V Permits are required for certain industry groups as designated by the EPA as well as facilities that emit at least:

- 100 tons per year of regulated pollutants; or
- 10 tons per year of any hazardous air pollutant; or
- 25 tons per year of any combination of hazardous air pollutants.

In North Carolina, the General Assembly enacted laws in 1991 and 1993 authorizing the Title V program. The legislature also established the North Carolina Clean Air Act Advisory Council to develop the programs needed to comply with the Clean Air Act, including the structure of the Title V permit fees. The Clean Air Act Advisory Council issued a final report in August 1992, and the Environmental Management Commission followed the council's recommendations in adopting rules for the state Title V Permit Program in 1994. The EPA gave interim approval to North Carolina's Title V Permit Program on December 15, 1995, with final approval pending certain rules changes, which have been submitted to EPA. EPA gave final approval, in October 2001.

The Clean Air Act as well as the N.C. General Assembly, the EPA, the EMC and the Clean Air Act Advisory Council all required or recommended accountability measures for the state Title V program. This Accountability Report includes:

- A discussion of program accomplishments and goals;
- A detailed description of the Title V permit fee structure for calendar year 2003;
- A detailed, line-item budget for state fiscal year 2003;
- An organizational chart for total staff in the Division of Air Quality and Title V related positions; and
- An account of Title V receipts and expenditures from state fiscal year 1992 to 2002;

The Division of Air Quality started receiving Title V permit applications after EPA's interim approval of the program on December 15, 1995. Facilities were given until December 1996 to submit their applications or they would be considered in violation of the permitting rules. Applications received during the aforementioned timeframe were called "Initial Title V Applications" and all other Title V applications received after December 1996 were called "First Time Title V Applications." By January 1998, DAQ had 475 Title V applications under review. Since program approval, the DAQ has received a total of 558 Title V applications (488 initial and 70 first time). To date DAQ

has issued all but one initial Title V permit and expects to issue this remaining permit before the end of the year. The issuance of the last permit has been delayed by the need for public hearing and recent comments by permit applicants. One hundred and eight of the initial Title V applications have been withdrawn due to reclassification or closure. To date DAQ has issued 51 of the First Time Title V permits and is currently reviewing 20 applications. Currently, DAQ has 382 operating facilities classified as Title V facilities.

Questions about this Accountability Report or request for copies should be directed to Charles Valrie, Division of Air Quality, Department of Environment and Natural Resources, 1641 Mail Service Center, Raleigh, NC 27699-1641; telephone (919) 715-6281; email: Charles.Valrie@ncmail.net.

ACCOMPLISHMENTS AND GOALS

The Division of Air Quality (DAQ), the Department of Environment and Natural Resources (DENR), and the North Carolina Environmental Management Commission (EMC) have accomplished the following measures in developing and carrying out a Title V Permit Program in North Carolina. Goals are included where applicable.

1. The DAQ has established a Title V Permit Program based on rules adopted by the EMC (15A NCAC 2Q .0500). The program meets the requirements of state law (N.C.G.S. §§143-215.3 and 143-215.108) that authorized the program in North Carolina and set up the North Carolina Clean Air Act Advisory Council. The EPA gave interim approval to the program in 1995, and following the DAQ's revision to the Title V regulations; EPA gave final program approval in October of 2001.

2. In 2002 the DAQ revised the Title V application forms including the development of special forms for the renewal of Title V permits. These revised forms are intended to facilitate the application process, and they have been placed on the Division's website (http://daq.state.nc.us).

3. The DAQ has developed a permit fee schedule that generates an appropriate amount of revenue to carry out the Title V permitting program. The Federal Clean Air Act requires that Title V permit holders pay fees sufficient to cover the cost to administer the permitting program. The DAQ will continue to evaluate the fee structure to ensure that the necessary fees are collected.

4. The DAQ has hired approximately 139 staff members to operate the Title V program since it started in 1992. The total staff size is still smaller than the projected size from the Final Report of the Clean Air Act Advisory Council and has remained constant for several years. There are no plans to increase the number of positions funded by the Title V fees above the current level.

5. DENR has established a Small Business Assistance Program, hired a Small Business Ombudsman, and appointed a Compliance Advisory Panel to conduct citizen overview of small business activity.

6. The DAQ continues to hold meetings, including quarterly Outside Involvement Committee meetings, to provide citizens and the regulated community the opportunity for input into DAQ's permitting and planning procedures.

7. DAQ provided and continues to provide a range of options to qualify facilities as Non-Title V facilities. Many facilities have taken advantage of these options, which is one of the reasons why the number of Title V facilities is much less than initial estimates; that is, 382 Title V facilities now versus the 2000 estimated in the Clean Air Act Advisory Council's Final Report. For example, the DAQ established the synthetic minor program so facilities could avoid the Title V permitting program by taking permitted emission limits and/or operating restrictions. Also, the EMC adopted and EPA approved exclusionary rules to

allow reasonable potential emission calculations in cases where standard methods would produce unreasonably high potential emissions thus subjecting such facilities to Title V. **Goal:** The DAQ will continue to issue appropriate permits to qualified facilities that wish to remain non-Title V facilities.

8. To date, DAQ has issued 402 permits (380 initial and 22 first time). **Goal:** DAQ will issue the one remaining initial permit by the end of December 2004.

9. In 1994 DAQ conducted its first comprehensive emissions inventory for all facilities in North Carolina. This comprehensive inventory process has been repeated every three years for all non-Title V facilities. In January 2003 the inventory requirement was changed to every five years for non-Title V facilities. Title V facilities continue to be required to submit an inventory annually. This emission information is stored on a computer database that DAQ uses to calculate fees and for use in regulatory planning. **Goal:** The DAQ has started to develop an electronic on-line inventory system and the system was made available to permittees to use in 2003.

CALENDAR YEAR 2003 PERMIT FEES TABLE

NOTES AND EXPLANATION

The federal Clean Air Act requires that the entire cost of the Title V Permit Program, including both direct and related expenses, be funded by facilities' permit fees and that Title V permit fees be used only for this purpose. The Clean Air Act also set a presumptive minimum for total fees at $25 per ton of air pollutant emissions in 1990 dollars, with a cost-of-living escalator that has raised this minimum to $37.43 in 2004 dollars. The Title V permit fees schedule for North Carolina now yields only 78 percent of the presumptive minimum. However, DAQ considers this amount adequate to run the program as long as all other funding sources for DAQ remain unchanged. The Title V permit fees are required by federal statutes and DAQ rules to be adjusted each January 1st by an official cost-of-living factor from the U.S. Environmental Protection Agency.

The Clean Air Act Advisory Council established by the General Assembly recommended in 1992 that the Title V permit fees should total $25 per ton of emission (adjusted annually for cost-of-living from the 1990 base), rather than the $36.45 per ton shown by the workload analysis in the council's final report. The council recommended this level so North Carolina could remain competitive with neighboring states — most of which were expected to use the $25/ton plus inflation presumptive minimum — and because of the many uncertainties in the program at that time.

The advisory council also considered the fairness of basing fees entirely on the amount of pollutants emitted, rather than on the amount of work required to administer Title V permits for various types of facilities. Because a certain amount of work is required to issue every Title V permit, regardless of the facility's emissions, the council recommended that half of the total Title V permit fees come from an applications fee (an annual flat fee for each permit) and the other half of the revenues come from annual per-ton charges.

A major uncertainty during the advisory council's work was the number of facilities that would be required to hold Title V permits and their emissions levels. This existed because a comprehensive emission inventory had never been required for all facilities. Since the council concluded its work, the EPA has issued many regulations, policies, clarifications, and changes to the Title V program, and the state has responded accordingly.

The state also has shown flexibility in the Title V program by using size exclusions for some industry groups (such as service stations, grain elevators, dry cleaners and emergency generators) and by allowing facilities to adopt permit limits that reduce their potential emissions below the Title V thresholds (known as synthetic minor sources). As a result, the number of Title V facilities has decreased from an estimated 2,000 in the Clean Air Act Advisory Council's Final Report, to 850 when the Title V permit fees schedule was adopted effective March 8, 1994, to about 382 facilities today. The total amount of emissions has changed little since the council's final report.

In Table I, "non-attainment" refers to permits issued under special rules applicable in areas that are in non-attainment with federal standards for criteria air pollutants such as ozone or carbon monoxide. "PSD" refers to permits issued under federal Prevention of Significant Deterioration rules. "NSR/NAA" refers to permits issued under special rules for New Source Review in Non-attainment Areas.

Another feature of the fee schedule that should be noted is that no permit application fee is charged for a simple renewal of a permit. In addition, no permit application fee is charged when the reason for the change is initiated by the director of the Division of Air Quality or the Environmental Management Commission, e.g., new control equipment required by a new rule or even the initial Title V permits for existing permitted sources.

CALENDAR YEAR 2005 PROJECTED TITLE V PERMIT FEES 10/21/2004

HISTORY
TITLE V FEES/ASSESSMENTS AND EXPENDITURES
EXPLANATION

DENR collected Title V assessments until the Environmental Management Commission adopted rules setting the permit fees schedule in 1994, as specified by the General Assembly in House Bill 551(N.C.G.S. 143-215.3 and 143-215.108). The rule adoption process occurred after the North Carolina Clean Air Act Advisory Council issued its final report in 1992, as specified by the legislature. Assessments were collected in state fiscal years 1992 (starting July 1, 1991) 1993, and 1994. The Title V permit fees set by rule were collected beginning in state fiscal year 1995 (starting July 1, 1994).

In 1997, facilities received a partial refund of Title V fees. This was accomplished by sending the facility a check, valued at 21 percent of the permit fees paid in 1997. This refund was to reduce the budgeted carry forward as of July 1, 1998.

The Division of Air Quality, based on an analysis of variability in fuel tax revenue, decided that it is prudent to have a carry forward of about 35 percent. The 35 percent is well within the statutory limitation that allows a state's Title V program to carry forward 100 percent of the expected cost of the Title V program for the next year. By terms of the Federal Clean Air Act, the entire cost of the Title V program must be paid with Title V permit fees, and Title V permit fees can only be used for this purpose.

ORGANIZATION CHART EXPLANATION

The organization chart shown in this document lists all the positions authorized by State Personnel for the Division of Air Quality. Positions that are funded using Title V fees are listed with a funding designation of 2333R. Additionally, positions outside the Division of Air Quality that are funded through the transfer of Title V funds are listed separately.

Implementation of the "Clean Smokestacks Act"

A Report to the Environmental Review Commission and the Joint Legislative Utility Review Committee

Submitted by the North Carolina Department of Environment and Natural Resources and the North Carolina Utilities Commission

June 1, 2004

Implementation of the "Clean Smokestacks Act"

A Report to the Environmental Review Commission and the Joint Legislative Utility Review Committee

Submitted by the North Carolina Department of Environment and Natural Resources and the North Carolina Utilities Commission

This report is submitted pursuant to the requirement of Section 14 of Session Law 2002-4, Senate Bill 1078 enacted June 20, 2002. The actions taken to date by Progress Energy Carolinas, Inc. and Duke Power, a Division of Duke Energy Corporation, appear to be in accordance with the provisions and requirements of the Clean Smokestacks Act.

Signed: _____

William G. Ross, Jr., Secretary
Department of Environment and Natural Resources

Signed: _____

Jo Anne Sanford, Chair
North Carolina Utilities Commission

June 1, 2004

Implementation of the "Clean Smokestacks Act"

A Report to the
Environmental Review Commission and the Joint Legislative Utility Review Committee

June 1, 2004

The General Assembly of North Carolina, Session 2001, passed Session Law 2002-4 also known as Senate Bill 1078. This legislation is titled "*An Act to Improve Air Quality in the State by Imposing Limits on the Emission of Certain Pollutants from Certain Facilities that Burn Coal to Generate Electricity and to Provide for Recovery by Electric Utilities of the Costs of Achieving Compliance with Those Limits*" ("the Clean Smokestacks Act" or "the Act"). The Clean Smokestacks Act, in Section 14, requires the Department of Environment and Natural Resources ("DENR") and the Utilities Commission ("Commission") to report annually, i.e., by June 1 of each year, on the implementation of the Act to the Environmental Review Commission and the Joint Legislative Utility Review Committee.

The Act, in Section 9, requires Duke Energy and Progress Energy to submit annual reports to DENR and the Commission containing certain specified information. Duke Energy and Progress Energy filed reports, with DENR and the Commission, dated March 31, 2004, and April 1, 2004, respectively. Specifically, such reports were submitted in compliance with the requirements of G.S. 62-133.6(i). Duke Energy's and Progress Energy's reports are attached, and made part of this report, as Attachments A and B, respectively.

Additionally, the Secretary of DENR wrote the Commission on May 3, 2004, as follows:

"North Carolina's investor owned electric utilities, Duke Energy and Progress Energy, have filed their compliance plan annual updates for 2004 in accordance with N.C.G.S. 62-133.6(i), Section 9(i) of S.L. 2002-4, known as the 'Clean Smokestacks Act'. Pursuant to N.C.G.S. 62-133.6(j), the Department of Environment and Natural Resources has reviewed this information, and the submittals comply with the Act. The plans and schedules of the companies appear adequate to achieve the emission limitations set out in N.C.G.S. 143-215.107D."

This report is presented to meet the reporting requirement of the Act pertaining to DENR and the Commission, as discussed above, and is submitted jointly by DENR and the Commission. The report is structured to address the various actions that have occurred pursuant to the provisions of Sections 9, 10, 12 and 13 of this Act. Reports of actions under these Sections describe the extent of implementation of the Act to this date.

I. Section 9(c) of the Act, Codified as Section 62-133.6(c) of the North Carolina General Statutes

G.S. 62-133.6(c) provides: *The investor-owned public utilities shall file their compliance plans, including initial cost estimates, with the Commission and the Department of Environment and Natural Resources not later than 10 days after the date on which this section becomes effective. The Commission shall consult with the Secretary of Environment and Natural Resources and shall consider the advice of the Secretary as to whether an investor-owned public utility's proposed compliance plan is adequate to achieve the emissions limitations set out in G.S. 143-215.107D.*

Status: North Carolina's investor-owned electric utilities, Progress Energy Carolinas, Inc. (Progress Energy) and Duke Power, a division of Duke Energy Corporation (Duke Energy), filed their initial compliance plans as required in June and July of 2002, in accordance with G.S. 62-133.6(c), Section 9(c) of S.L. 2002-4, the Clean Smokestacks Act. DENR reviewed this information and determined that the submittals comply with the Act and, as proposed, appear adequate to achieve the emission limitations set out in G.S. 143-215.107D.

II. Section 9(i) of the Act, Codified as Section 62-133.6(i) of the North Carolina General Statutes

G.S. 62-133.6(i) provides: *An investor-owned public utility that is subject to the emissions limitations set out in G.S. 143-215.107D shall submit to the Commission and to the Department of Environment and Natural Resources on or before 1 April of each year a verified statement that contains all of the following [specified information]:*

The following are the eleven subsections of G.S. 62-133.6(i) and the related responses from Progress Energy and Duke Energy for each subsection:

1. **G.S. 62-133.6(i)(1) requires:** *A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.*

Progress Energy Response: "The plan for Progress Energy Carolinas, Inc. was originally submitted on July 29, 2002. Appendix A (of the attached Progress submittal dated April 1, 2004) contains an updated version of this plan, effective April 1, 2004."

Duke Energy Response: "Exhibits A and B (of the attached Duke submittal dated March 31, 2004) outline the technology selections by facility and unit, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with G.S. 143-215.107D."

2. **G.S. 62-133.6(i)(2) requires:** *The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed during that year.*

Summary of Progress Energy Report: The actual environmental compliance costs incurred by Progress Energy in calendar year 2003 were $22.3 million. Construction began at both Roxboro and Asheville plants after receipt of the necessary Title V permits and approval of soil and erosion control plans.

Summary of Duke Energy Report: The actual environmental compliance costs incurred by Duke Energy in calendar year 2003 were $16.0 million. The Company reported that such costs were incurred for such things as a variety of project studies and investigations, engineering, equipment specifications development, equipment layout, contracting related costs, and logistics.

3. **G.S. 62-133.6(i)(3) requires:** *The amount of the investor-owned public utility's environmental compliance cost amortized in the previous calendar year.*

Summary of Progress Energy and Duke Energy Reports: Progress Energy amortized $74.2 million in 2003. Duke Energy amortized $114.8 million in 2003. As indicated in the May 30, 2003 report to the Environmental Review Commission and the Joint Legislative Utility Review Committee ("the May 30, 2003 report"), Progress Energy, in response to a data request submitted by the Commission, projected that it would amortize $100 million of environmental compliance costs in 2003. Also, as indicated in the May 30, 2003 report, Duke Energy, in response to a Commission data request, projected that it would amortize $70 million of environmental compliance costs in 2003.

4. **G.S. 62-133.6(i)(4) requires:** *An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.*

Summary of Progress Energy Report: Progress Energy reported that, while some unit total and annual costs have changed, the total project cost in future dollars remains at $813 million. More specifically, in its 2004 report, the Company estimated such cost to be $812.968 million, as compared to the $813.119 million reflected in its 2003 report, a reduction of $151,000. The Company observed that the projected SO_2 removal rates have increased for scrubbed units. As a result, the planned scrubber for Lee 3 has been cancelled

Summary of Duke Energy Report: Duke Energy reported that its expected costs are not significantly different than the estimates provided in 2003. More specifically, in its 2004 report, the Company estimated its compliance costs to be $1.526 billion, as compared to the $1.479 billion reflected in its 2003 report, an increase of $47 million. The Company also reported that the technologies expected to be required to support compliance have not changed. The Company further stated that the

minor adjustments to the estimates at the project level are the result of additional project scope definition and refinement of project schedules only.

5. **G.S. 62-133.6(i)(5) requires:** *A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.*

Progress Energy Response:

Asheville Plant

- Revised Title V permits to support construction activities have been issued
- NPDES Permit application submitted for required wastewater system modifications
- Soil erosion and sedimentation control plans have been approved

Roxboro Plant

- Revised Title V permits to support construction activities have been issued
- Soil erosion and sedimentation control plans have been approved

Duke Energy Response:

"Allen Steam Station SNCR, Unit 1

- Air Permit Application for temporary trial submitted and final permit received in 2002
- NPDES Permit Modification for temporary trial submitted and permit modification received in 2002
- Air Permit Application for permanent equipment installation submitted and final permit received in 2002

Marshall Steam Station SNCR, Unit 4

- Air Permit Application for temporary trial submitted and final permit received in 2002
- NPDES Permit Modification for temporary trial submitted and permit modification received in 2002
- Marshall Steam Station Scrubbers, Units 1-4
  - Air Permit Application – Submitted 9/17/03; received 2/5/04
  - Sedimentation and Erosion Control Plan – Submitted 9/11/03; received 10/8/03; amended 12/19/03; amendments approved 12/31/03
  - NPDES Modification – Submitted 4/30/03; received 1/23/04
  - Landfill Site Suitability Application – Submitted 9/3/03"

6. **G.S. 62-133.6(i)(6) requires:** *A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.*

Progress Energy Response: See Appendix C of the attached letter from Progress Energy dated April 1, 2004, for details of construction and installation of equipment. The Asheville and Roxboro plants will have significant construction in 2004.

Duke Energy Response: See attached letter from Duke Energy dated March 31, 2003, for details of construction anticipated for the next year for:

- Allen Steam Station SNCR, Unit 3
- Allen Steam Station SNCR, Unit 4
- Allen Steam Station Scrubbers
- Belews Creek Steam Station Scrubbers
- Buck Steam Station SNCR, Unit 5
- Buck Steam Station SNCR, Unit 6
- Cliffside Steam Station Scrubbers
- Marshall Steam Station SNCR, Unit 1
- Marshall Steam Station SNCR, Unit 2
- Marshall Steam Station SNCR, Unit 3
- Marshall Steam Station Scrubbers
- Riverbend Steam Station SNCR, Unit 4
- Riverbend Steam Station Burners, Unit 5
- Riverbend Steam Station SNCR, Unit 7

7. **G.S. 62-133.6(i)(7) requires:** *A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.*

Progress Energy Response: "An NPDES permit modification application will be submitted in the 2nd quarter of 2004 to request changes to the existing wastewater discharge permit for the Roxboro Plant. Operation of scrubbers to comply with G.S. 143-214.107D will create a new wastewater stream, which requires modification of our current permit. The application characterizes expected wastewater contaminant concentrations and flows."

Duke Energy Response:

"Allen Steam Station SNCR, Unit 3

- Air Permit Application – Plan to submit 8/1/04

Belews Creek Steam Station Scrubbers, Units 1-2

- Landfill Site Suitability Application – Plan to submit 1/11/05
- Air Permit Application – Plan to submit 5/20/05
- Sedimentation and Erosion Control Plan – Plan to submit 6/6/05
- NPDES Permit Application – Plan to submit 5/25/04

Dan River Steam Station SOFA, Unit 3

- Air Permit Application – Plan to submit January , 2005

Marshall Steam Station SNCR, Unit 2

- Air Permit Application – Plan to submit June, 2005

Marshall Steam Station SNCR, Unit 3

- Air Permit Application – Plan to submit 6/1/04
- NPDES Permit Modification (if required) – Plan to submit 10/27/04

- Sedimentation and Erosion Control (if required) – Plan to submit 11/15/04

Marshall Steam Station Scrubbers

- Landfill Construction Plan Application – Plan to submit 4/1/04
- Sedimentation and Erosion Control Plan for balance of Marshall site work – Plan to submit 6/18/04
- Authorization to Construct (ATC) application for FGD wastewater treatment system – Plan to submit 6/1/04

Riverbend Steam Station SOFA, Unit 5

- Air Permit Application – Plan to submit 5/1/04

Riverbend Steam Station SOFA, Unit 6

- Air Permit Application – Plan to submit January, 2005"

8. **G.S. 62-133.6(i)(8) requires:** *The results of equipment testing related to compliance with G.S. 143-215.107D.*

Progress Energy Response: "No equipment testing related to compliance with G.S. 143-215.107D occurred in 2003."

Duke Energy Response:

"Allen Steam Station SNCR, Unit 1

- Technology demonstration in December, 2001 (one week test)
  - Nominal 30% reduction in NOx with ammonia slip of 5 to 10 ppm at full load
  - Average NOx outlet rate of 0.15 #/MMBTU for the test period
- Equipment acceptance testing in November, 2003
  - Nominal 25% reduction in NO_x with ammonia slip of less than 5 ppm at full load

Marshall Steam Station SNCR, Unit 4

- Technology demonstration in October - November, 2002 (one month test)
  - Average 24% - 25% reduction in NOx with ammonia slip of 5 to 10 ppm at full load
  - Average NO_x outlet rate of 0.163 #/MMBTU for the test period "

9. **G.S. 62-133.6(i)(9) requires:** *The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.*

Progress Energy Response: "The total calendar year 2003 emissions from the affected coal-fired Progress Energy Carolinas units are:

- NOx - 56,059
- SO_2 - 196,184"

Duke Energy Response: In the 2003 calendar year, the following were emitted from the North Carolina based Duke Energy coal-fired units:

- NOx - 75,550 tons
- SO2 - 264,031 tons

10. **G.S. 62-133.6(i)(10) requires:** *The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.*

Progress Energy Response: "No emissions allowances resulting from compliance with G.S. 143-215.107D were acquired in 2003."

Duke Energy Response: "No emissions allowances have been acquired by Duke Power Company resulting from compliance with the limitations set out in G.S. 143-215.107D."

11. **G.S. 62-133.6(i)(11) requires:** *Any other information requested by the Commission or the Department of Environment and Natural Resources*

Summary of Commission Request: The Commission submitted data requests to Progress Energy and Duke Energy on April 16, 2004. The information requested, among other things, concerned current projected amortization schedules over the six remaining years of the seven-year accelerated cost recovery period.

Progress Energy Response: Progress Energy responded that it currently expects to amortize its remaining compliance costs as follows: 2004 - $75 million; 2005 – $120 to $140 million; 2006 - $125 to $145 million; 2007 – $130 to $150 million; 2008 - $121.5 million; and 2009 - $121.5 million. The Company noted that those amounts are subject to change.

Duke Energy Response: Duke Energy responded that it currently plans to amortize its remaining compliance costs as follows: 2004 - $171 million; 2005 – $277 million; 2006 - $277 million; 2007 – $277 million; 2008 - $214 million; and 2009 - $169 million.

III. Section 10 of the Act provides: *It is the intent of the General Assembly that the State use all available resources and means, including negotiation, participation in interstate compacts and multistate and interagency agreements, petitions pursuant to 42 U.S.C. § 7426, and litigation to induce other states and entities, including the Tennessee Valley Authority, to achieve reductions in emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) comparable to those required by G.S. 143-215.107D, as*

enacted by Section 1 of this act, on a comparable schedule. The State shall give particular attention to those states and other entities whose emissions negatively impact air quality in North Carolina or whose failure to achieve comparable reductions would place the economy of North Carolina at a competitive disadvantage.

DENR and Division of Air Quality (DAQ) Activities to implement this Section:

- A meeting was held between DENR/DAQ and the Tennessee Valley Authority (TVA) and the Tennessee air program officials in August 2002, to discuss actions planned by TVA that would be comparable to the Clean Smokestacks Act. TVA presented their plans to add five additional SO2 scrubbers to power plants primarily in the eastern portion of the TVA system. These new scrubbers should benefit North Carolina most. TVA plans to complete installation of the new facilities by 2010 and the first plant, Paradise, will be installed by 2006. Regarding NOx control, TVA is on schedule to have the first 8 of its selective catalytic reduction (SCR) systems in place. TVA plans to have 25 boiler units controlled by 2005 at a cost of $1.3 billion which will reduce ozone season NOx by 75 percent.

Through DENR's efforts, the Clean Smokestacks Act is achieving notoriety nationally and is being touted in other States as a model for State action. The Secretary of DENR and the Chief of Planning of DAQ made presentations about the Clean Smokestacks Act at two national state environmental organization meetings in the fall of 2002. The Chief of Planning of DAQ testified in 2002, at a U.S. Senate Environment and Public Works Committee Hearing on the features and benefits of North Carolina's Clean Smokestacks Act. The Deputy Director of DAQ participates on a national dialogue workgroup addressing ideal features of national multi-pollutant legislation for coal-fired utility boilers. The Clean Smokestacks Act is held up as an ideal example.

- The State also has been active in maintaining federal standards. In an April 2003 letter to EPA Administrator Whitman, Governor Easley urged the Administration to ensure that the federal Clear Skies bill not override State initiatives such as the Clean Smokestacks Act. The Governor also indicated the State's opposition to bill text that would extinguish the statutory rights of States regarding interstate pollution abatement. DAQ and the Attorney General commented last month in opposition to a proposed federal rule that would weaken the federal New Source Review program and potentially result in significant new upwind emissions. North Carolina filed a petition on March 18, 2004, calling for the U.S. Environmental Protection Agency to require major reductions of air pollution in 13 upwind states that are significantly impacting this state. Reducing these emissions will substantially improve air quality in North Carolina. The petition, filed pursuant to Section 126 of the Clean Air Act, calls for the EPA to require cuts in fine particle-forming emissions from power plants in Alabama, Georgia, Illinois, Indiana, Kentucky, Michigan, Ohio, Pennsylvania,

South Carolina, Tennessee, Virginia and West Virginia, and ozone-forming emissions in Georgia, Maryland, South Carolina, Tennessee and Virginia.

IV. Section 12 of the Act provides: *The General Assembly anticipates that measures implemented to achieve the reductions in emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required by G.S. 143-215.107D, as enacted by Section 1 of this act, will also result in significant reductions in the emissions of mercury from coal-fired generating units. The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to monitoring emissions of mercury and the development and implementation of standards and plans to implement programs to control emissions of mercury from coal-fired generating units. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of mercury. The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than 1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of mercury from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of mercury is reduced as a result of the reductions in the emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.*

DAQ Actions to Implement this Section: The DAQ submitted a report on September 1, 2003, as required by this section. The first report primarily focused on the "state of knowledge" of the co-benefit of mercury control that will result from the control of NOx and SO2 from coal-fired utility boilers. Also, preliminary estimates were made for this co-benefit for the North Carolina utility boilers based on the initial plans submitted by Progress Energy and Duke Energy. Two public workshops were held in June and July 2003, to meet with all interested stakeholders to offer review of the draft DAQ report. DAQ is presently developing the September 1, 2004 report.

V. Section 13 of the Act provides: *The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to the development and implementation of standards and plans to implement programs to control emissions of carbon dioxide (CO2) from coal-fired generating units and other stationary sources of air pollution. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of carbon dioxide (CO2). The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than*

1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of carbon dioxide (CO2) from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of carbon dioxide (CO2) is reduced as a result of the reductions in the emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.

DAQ Actions to Implement this Section: The DAQ submitted a report on September 1, 2003, as required by this section. The first report primarily focused on the "state of knowledge" and actions being taken or planned elsewhere regarding CO2 control from coal-fired utility boilers. Two public workshops were held in June and July 2003, to meet with all interested stakeholders to offer review of the draft DAQ report.

VI. Supplementary Information: As stated in the May 30, 2003 report, the Public Staff – North Carolina Utilities Commission (Public Staff) will audit the books and records of Progress Energy and Duke Energy in regard to the costs incurred and amortized by the Companies concerning their compliance with the provisions of the Clean Smokestacks Act. The Public Staff has undertaken such a review, focusing on the verification of costs related to complying with the Act, the amortization of those costs, and contracts with vendors who will engineer and construct emission reduction equipment. The Public Staff filed its reports with the Commission on May 3, 2004. Attached, and made part of this report, are the Public Staff's reports for Duke Energy and Progress Energy (without Attachment), Attachments C and D, respectively.

CONCLUSION

Actions taken to date by Progress Energy and Duke Energy appear to be in accordance with the provisions and requirements of the Clean Smokestacks Act.

ATTACHMENTS

Attachment A: Clean Smokestacks Act Compliance Plan Annual Update dated March 31, 2004, Submitted by Duke Power, a Division of Duke Energy Corporation

Attachment B: Annual North Carolina Clean Smokestacks Act Compliance Report dated April 1, 2004, Submitted by Progress Energy Carolinas, Inc.

Attachment C: Report of the Public Staff on Costs Incurred and Amortized by Duke Energy Corporation in Compliance with Session Law 2002-4

Attachment D: Report of the Public Staff on Costs Incurred and Amortized by Progress Energy Carolinas, Inc. in Compliance With Session Law 2002-4

Subject: Senate Bill 1078

Duke Power Compliance Plan Annual Update

Record No. NC CAP 003
Certified: 7002 3150 0003 7316 2413

Dear Ms. Sanford:

As required by Senate Bill 1078, Duke Power is required to file information on or before 1 April of each year to update the Commission on progress to date, upcoming activities and expected strategies to achieve the emissions limitations set out in G.S. 143-215.107D.

The current plan to meet the emission requirements for NO_x and SO_2 continues to include:

NO_x Control – The installation of Selective Catalytic Reduction (SCR) on Cliffside Steam Station Unit 5 and Belews Creek Steam Station Units 1&2; the installation of Selective Non Catalytic Reduction (SNCR) with Low-NO_x burners on the 24 remaining units.

SO_2 Control – The installation of wet scrubbers on our twelve largest generating units.

Exhibits A and B outline the unit specific technology selections, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the legislative requirements. The projected 'environmental compliance costs' for these pollution control projects are included in Exhibit C.

Duke Power will continue to optimize the technology selection, implementation schedule and cost, and will provide annual updates to the NC Utilities Commission as required. If you have questions regarding any aspect of our plan, please do not hesitate to contact my office at 704-373-4363.

Sincerely,

George T. Everett

Duke Power Company

General Assembly of North Carolina Session 2001
Senate Bill 1078 – Improve Air Quality/Electric Utilities (NC Clean Air Legislation)
Annual Data Submittal

1. **A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.**

   Exhibits A and B outline the technology selections by facility and unit, projected operational dates, expected emission rates, and the corresponding tons of emissions that demonstrate compliance with the provisions of G.S. 143-215.107D.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed during that year.**

   In the 2003 calendar year, Duke Power Company spent $16,041,000 on activities in support of compliance with the provisions of G.S. 143-215.107D. Exact amounts associated with each project are provided in Exhibit C, and a description of the associated activities is provided below:

   Allen Steam Station SNCR, Unit 1
   - Equipment installation completed
   - Acceptance testing completed

   Allen Steam Station SNCR, Unit 3
   - Project planning and scope development initiated
   - Boiler testing and modeling completed

   Allen Steam Station SNCR, Unit 5
   - Project planning and scope development initiated

   Allen Steam Station Scrubbers
   - Project studies and investigations related to reagent handling, equipment optimization, byproduct handling, equipment layout and logistics completed

   Belews Creek Steam Station Scrubbers
   - Project studies and investigations related to reagent handling, equipment optimization, byproduct handling, equipment layout and logistics completed

   Cliffside Steam Station Scrubbers
   - Project studies and investigations related to reagent handling, equipment optimization, byproduct handling, equipment layout and logistics completed

   Dan River Steam Station Burners, Unit 3
   - Electrical and mechanical design continued

   Marshall Steam Station SNCR, Unit 1
   - Project planning and scope development initiated

Marshall Steam Station SNCR, Unit 2

- Project planning and scope development initiated
- Boiler testing and modeling completed

Marshall Steam Station SNCR, Unit 3

- SNCR Equipment engineering completed

Marshall Steam Station SNCR, Unit 4

- SNCR Equipment engineering completed

Marshall Steam Station Scrubbers

- Initial engineering phase for balance of plant (BOP) scope completed
- Approximately 25% of detailed engineering completed
- EPC contract for FGD Project awarded on December 19, 2003

Riverbend Steam Station Burners, Unit 5

- Electrical and mechanical design continued

Riverbend Steam Station Burners, Unit 6

- Electrical and mechanical design continued

3. **The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.**

   In the 2003 calendar year, **$114,813,336** was amortized related to construction work activity in support of compliance with the provisions of G.S. 143-215.107D.

4. **An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.**

   The estimated 'environmental compliance costs' as defined in G.S. 143-215.107D are provided in Exhibit C.

   These expected costs are not significantly different than the estimates provided in the 2003 annual filing. The minor adjustments to the estimates at the project level are the result of additional project scope definition and refinement of project schedules only.

   The technologies expected to be required to support compliance have not changed from what was provided in the 2003 annual filing or subsequent data requests. These technology decisions continue to be evaluated more fully, and changes to these technology decisions may ultimately be required in order to comply with emissions limitations.

5. **A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.**

Allen Steam Station SNCR, Unit 1

- Air Permit Application for temporary trial submitted and final permit received in 2002
- NPDES Permit Modification for temporary trial submitted and permit modification received in 2002
- Air Permit Application for permanent equipment installation submitted and final permit received in 2002

Marshall Steam Station SNCR, Unit 4

- Air Permit Application for temporary trial submitted and final permit received in 2002
- NPDES Permit Modification for temporary trial submitted and permit modification received in 2002

Marshall Steam Station Scrubbers, Units 1-4

- Air Permit Application – Submitted 9/17/03; received 2/5/04
- Sedimentation and Erosion Control Plan – Submitted 9/11/03; received 10/8/03; amended 12/19/03; amendments approved 12/31/03
- NPDES Modification – Submitted 4/30/03; received 1/23/04
- Landfill Site Suitability Application – Submitted 9/3/03

6. **A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.**

Allen Steam Station SNCR, Unit 3

- SNCR equipment engineering expected to occur in 2004
- SNCR equipment installation expected to occur in 2nd quarter of 2005

Allen Steam Station SNCR, Unit 4

- Boiler testing and modeling expected to occur in 2004

Allen Steam Station Scrubbers

- No FGD construction planned in 2004-2005, and no further substantial FGD engineering anticipated until 2008

Belews Creek Steam Station Scrubbers

- Further FGD engineering study expected to be awarded in 3rd or 4th quarter of 2004 to finalize FGD project scope, funding, and implementation schedule
- EPC contract expected to be awarded in 3rd quarter of 2005
- Release for detailed engineering and potentially authorization for some early site prep may be awarded under a Limited Notice To Proceed (LNTP) to the EPC Contractor in 2nd quarter of 2005
- Full site mobilization of the EPC Contractor expected to begin in the 3rd quarter of 2005

- Only substantial construction expected to be started in 2005 would be general excavation, grading, and drainage
- Foundations may be started in 4th quarter of 2005

Buck Steam Station SNCR, Unit 5

- Boiler testing and modeling expected to occur in 2004
- SNCR equipment engineering expected to begin in 2004

Buck Steam Station SNCR, Unit 6

- Boiler testing and modeling expected to occur in 2004
- SNCR equipment engineering expected to begin in 2004

Cliffside Steam Station Scrubbers

- No FGD construction planned in 2004-2005, and no further substantial FGD engineering anticipated until 2006

Marshall Steam Station SNCR, Unit 1

- SNCR equipment engineering expected to begin in 2004

Marshall Steam Station SNCR, Unit 2

- SNCR equipment engineering expected to begin in 2004

Marshall Steam Station SNCR, Unit 3

- SNCR equipment installation expected to be completed by 2nd quarter of 2005

Marshall Steam Station Scrubbers

- EPC Contractor began mobilization at site on January 5, 2004
- Site prep (timber clearing) began in January and finished in March, 2004
- General excavation, grading, and drainage expected to start in April, 2004
- Installation of foundations expected to begin in June, 2004
- Erection of new wet stack (concrete wind screen) and installation of undergrounds (electrical duct bank and piping) expected to begin in September, 2004
- Erection of scrubber (absorber) building structural steel expected to begin in January, 2005
- Excavation and drainage for gypsum by-product landfill expected to start in February, 2005
- Erection of FGD ductwork structural support steel expected to begin in June, 2005
- Installation of FGD wastewater pre-treatment package (clarifier for removal of solid fines) expected to begin in July, 2005
- Switchyard tie-in and electrical power backfeed to FGD equipment expected to occur in November 2005.

Riverbend Steam Station SNCR, Unit 4

- Boiler testing and modeling expected to begin in 2004

Riverbend Steam Station Burners, Unit 5

- Installation of burners expected to be completed by 4th quarter of 2004

Riverbend Steam Station SNCR, Unit 7

- Boiler testing and modeling expected to begin in 2004

7. A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.

Allen Steam Station SNCR, Unit 3
- Air Permit Application – Plan to submit 8/1/04

Belews Creek Steam Station Scrubbers, Units 1-2
- Landfill Site Suitability Application – Plan to submit 1/11/05
- Air Permit Application – Plan to submit 5/20/05
- Sedimentation and Erosion Control Plan – Plan to submit 6/6/05
- NPDES Permit Modification – Plan to submit 5/25/04

Dan River Steam Station SOFA, Unit 3
- Air Permit Application – Plan to submit January, 2005

Marshall Steam Station SNCR, Unit 2
- Air Permit Application – Plan to submit June, 2005

Marshall Steam Station SNCR, Unit 3
- Air Permit Application – Plan to submit 6/1/04
- NPDES Permit Modification (if required)- Plan to submit 10/27/04
- Sedimentation and Erosion Control (if required) – Plan to submit 11/15/04

Marshall Steam Station Scrubbers
- Landfill Construction Plan Application – Plan to submit 4/1/04
- Sedimentation and Erosion Control Plan for balance of Marshall site work – Plan to submit 6/18/04
- Authorization to Construct (ATC) application for FGD wastewater treatment system – Plan to submit 6/1/04

Riverbend Steam Station SOFA, Unit 5
- Air Permit Application – Plan to submit 5/1/04

Riverbend Steam Station SOFA, Unit 6
- Air Permit Application – Plan to submit January, 2005

8. The results of equipment testing related to compliance with G.S. 143-215.107D.

Allen Steam Station SNCR, Unit 1
- Technology demonstration in December, 2001 (one week test)
  - Nominal 30% reduction in NO_x with ammonia slip of 5 to 10 ppm at full load
  - Average NO_x outlet rate of 0.15 #/MMBTU for the test period
- Equipment acceptance testing in November, 2003
  - Nominal 25% reduction in NO_x with ammonia slip of less than 5 ppm at full load

Marshall Steam Station SNCR, Unit 4

- Technology demonstration in October - November, 2002 (one month test)
  - Average 24% - 25% reduction in NO_x with ammonia slip of 5 to 10 ppm at full load
  - Average NO_x outlet rate of 0.163 #/MMBTU for the test period

Note: Test results do not necessarily guarantee long term results. Expected annual emission rates are provided in Exhibit A.

9. The number of tons of oxides of nitrogen (NO_x) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.

In the 2003 calendar year, 75,550 tons of NO_x and 264,031 tons of SO_2 were emitted from the North Carolina based Duke Power Company coal-fired units located in North Carolina and subject to the emissions limitations set out in G.S 143-215.107D.

10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

No emissions allowances have been acquired by Duke Power Company resulting from compliance with the emissions limitations set out in G.S. 143-215.107D.

11. Any other information requested by the Commission or Department of Environment and Natural Resources.

No additional information has been requested to be included in this annual data submittal.

Expected Duke Power Company Compliance Plan for NC Clean Air Plan

VERIFICATION

I, George T. Everett, state and attest that the attached information updating the North Carolina Utilities Commission on progress to date, upcoming activities, and expected strategies to achieve the emissions limitations set out in N. C. G.S.143-215.107.D (Annual Update) is filed on behalf of Duke Power, a division of Duke Energy; that I have reviewed said Annual Update and, in the exercise of due diligence, have made reasonable inquiry into the accuracy of the information provided therein; and that, to the best of my knowledge, information, and belief, all of the information contained therein is accurate and true, and no material information or fact has been knowingly omitted or misstated therein.

George T. Everett

Re: Annual NC Clean Smokestacks Legislation Compliance Report

Dear Mrs. Thigpen:

Progress Energy Carolinas, Inc. submits the attached report for calendar year 2003 regarding the status of compliance with the provisions of the North Carolina Clean Smokestacks legislation. Section 9(i) of the legislation requires that an annual report of compliance progress be submitted to the Commission by April 1 of each year for the previous calendar year.

Very truly yours,

Len S. Anthony
Deputy General Counsel

Dear Secretary Ross:

Progress Energy Carolinas, Inc. submits the attached report for calendar year 2003 regarding the status of compliance with the provisions of the North Carolina Clean Smokestacks legislation. Section 9(i) of the legislation requires that an annual report of compliance progress be submitted by April 1 of each year for the previous calendar year. Progress Energy Carolinas looks forward to continuing to work with you and your staff in processing the necessary permits that will facilitate the company's compliance with this important legislation.

Please feel free to contact me at (919) 546-2449 if you have any questions.

Sincerely,

Charles Wakild

Progress Energy Carolinas, Inc.
Senate Bill 1078 – Clean Smokestacks Law
Calendar Year 2003 Progress Report

On June 20, 2002, North Carolina Senate Bill 1078, also known as the "Clean Smokestacks Law," was signed into effect. This law requires significant reductions in the emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. Section 9(i) of the bill, which is now incorporated as Section 62-133.6(i) of the North Carolina General Statutes, requires that an annual progress report regarding compliance with the Clean Smokestacks Law be submitted on or before April 1 of each year. The report must contain the following elements, taken verbatim from the statute:

1. A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.
2. The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.
3. The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.
4. An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.
5. A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.
6. A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.
7. A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.
8. The results of equipment testing related to compliance with G.S. 143-215.107D.
9. The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.
10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.
11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

Information responsive to each of these report elements follows. The responses are given by item number in the order in which they are presented above.

1. **A detailed report on the investor-owned public utility's plans for meeting the emissions limitations set out in G.S. 143-215.107D.**

The plan for Progress Energy Carolinas, Inc. was originally submitted on July 29, 2002. Appendix A contains an updated version of this plan, effective April 1, 2004.

2. **The actual environmental compliance costs incurred by the investor-owned public utility in the previous calendar year, including a description of the construction undertaken and completed that year.**

Appendix B contains the costs incurred toward compliance with G.S. 143-215.107D in 2003 and the projected costs for future years through 2013.

Construction began in the fourth quarter of 2003 at both Roxboro and Asheville plants after receipt of the necessary Title V permits and approval of soil and erosion control plans. At Asheville, the general contractor mobilized, soil erosion and control measures were installed, site preparation began, various underground piping was relocated, and production piles for the new chimney and absorber foundations were started.

At the Roxboro plant, soil and erosion control measures were installed, and excavation began for the relocation of the existing coal dumper to allow for installation of the new scrubber absorber towers, chimneys, and other flue gas desulfurization equipment.

3. **The amount of the investor-owned public utility's environmental compliance costs amortized in the previous calendar year.**

Progress Energy Carolinas, Inc. amortized $74,218,806.00 in 2003.

4. **An estimate of the investor-owned public utility's environmental compliance costs and the basis for any revisions of those estimates when compared to the estimates submitted during the previous year.**

Appendix B contains the costs incurred toward compliance with G.S. 143-215.107D in 2003 and the projected costs for future years through 2013. The estimated total capital costs (escalated) remain $813M. Projected SO_2 removal rates have increased for scrubbed units. As a result, the planned scrubber for Lee 3 has been cancelled.

5. **A description of all permits required in order to comply with the provisions of G.S. 143-215.107D for which the investor-owned public utility has applied and the status of those permits or permit applications.**

Revised Title V permits to support construction activities for compliance with G.S. 143-215.107D have been issued for Asheville Plant (WNCRAQA Permit 11-628-03) and Roxboro Plant (NCDENR Permit 01001T31). We have no pending air permit applications. Progress Energy has submitted an NPDES Permit application package for required wastewater system modifications at Asheville Plant, and will be submitting the same for Roxboro Plant in 2004. The Asheville NPDES permit submittal includes an innovative constructed wetland treatment system, and the same is being evaluated for the Roxboro Plant. Soil erosion and sedimentation control plans have been submitted and approval received for the Asheville and Roxboro projects.

6. **A description of the construction related to compliance with the provisions of G.S. 143-215.107D that is anticipated during the following year.**

Appendix C presents the planned construction schedule for compliance with G.S. 143-215.107D. Note that this is a projected schedule of construction activity through 2013 that will be subject to modification. The schedule will be updated as part of this report each year.

Significant construction activities at Asheville during 2004 will include the erection of a new chimney to handle the lower temperature flue gas from the scrubbers, the absorber towers for both units, and various other scrubber support systems. At Roxboro, the significant construction activities in 2004 will focus on installation of a new limestone unloading facility and coal unloading facility to allow installation of the scrubber equipment beginning in 2005

7. **A description of the applications for permits required in order to comply with the provisions of G.S. 143-215.107D that are anticipated during the following year.**

An NPDES permit modification application will be submitted in the 2nd quarter of 2004 to request changes to the existing wastewater discharge permit for Roxboro Plant. Operation of scrubbers to comply with G.S. 143-214.107D will create a new wastewater stream, which requires modification of our current permit. The application characterizes expected wastewater contaminant concentrations and flows.

8. **The results of equipment testing related to compliance with G.S. 143-215.107D.**

No equipment testing related to compliance with G.S. 143-215.107D occurred in 2003.

9. **The number of tons of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) emitted during the previous calendar year from the coal-fired generating units that are subject to the emissions limitations set out in G.S. 143-215.107D.**

The total calendar year 2003 emissions from the affected coal-fired Progress Energy Carolinas units are:

NOx 56,059
SO_2 196,184

10. The emissions allowances described in G.S. 143-215.107D(i) that are acquired by the investor-owned public utility that result from compliance with the emissions limitations set out in G.S. 143-215.107D.

No emissions allowances resulting from compliance with G.S. 143-215.107D were acquired in 2003.

11. Any other information requested by the Commission or the Department of Environment and Natural Resources.

NC Clean Smokestacks Audit Public Staff Data Request No. 1 was issued to Progress Energy in September of 2003, and a response was provided on October 6, 2003 .

Appendix A

Progress Energy's Air Quality Improvement Plan Supplement
April 1, 2004

On June 20, 2002 Governor Easley signed into law SB1078 which caps emissions of nitrogen oxides (NOx) and sulfur dioxide (SO_2) from utility owned coal-fired power plants located in North Carolina. Progress Energy's annual NOx emissions must be less than 25,000 tons beginning in 2007 and annual SO_2 emissions must be less than 100,000 tons beginning in 2009 and less than 50,000 tons beginning in 2013. The emissions caps are cumulative for all coal-fired units in North Carolina. These caps represent a 56% reduction in NOx emissions from 2001 levels and a 74% reduction in SO_2 from 2001 levels for Progress Energy.

Progress Energy owns and operates 18 coal-fired units at seven plants in North Carolina. The locations of these plants are shown on Attachment 1.

Nitrogen Oxides Emissions Control Plan

Progress Energy has been evaluating and installing NOx emissions controls on its coal-fired power plants since 1995 in order to comply with Title IV of the Clean Air Act and the NOx SIP Call rule adopted by the Environmental Management Commission (EMC). Substantial NOx emissions reductions have already been achieved (56,000 tons of NOx in 2003 compared with 112,000 tons in 1997) and further reductions will ensure compliance with the SB1078 target of 25,000 tons in calendar year 2007. This target will be achieved with a mix of combustion controls (which minimize the formation of NOx) such as low NOx burners and over fire air technologies, and post-combustion controls (which reduce NOx produced during the combustion of fossil fuel to molecular nitrogen) such as selective catalytic reduction and selective non-catalytic reduction technologies. Attachment 2 details Progress Energy's North Carolina coal-fired electric generating units, their name plate generation capacity, and identifies the control technologies already installed and planned for installation. As technologies evolve or other circumstances change, a different mix of controls may be selected. Attachment 2 also projects the NOx emissions on a unit by unit basis based on the energy demand forecast and expected efficiencies of the NOx emissions controls employed. This information is provided only to show how compliance may be achieved and is not intended in any way to suggest unit specific emission limits. Actual emissions for each unit may be substantially different in 2007.

Flue Gas Desulfurization (FGD)

Progress Energy has completed screening studies on its coal-fired units at Asheville, Roxboro and Mayo plants. Wet scrubbers will be installed at these plants to remove 97% of the SO2 emissions. Babcock and Wilcox has been selected as the equipment supplier,

and Fluor Enterprises has been selected as the general contractor for the installation of the SO2 and NOx controls.

Wet scrubbers and dry scrubbers produce unique waste and by-product streams. Issues related to wastewater permitting and solid waste disposal are being addressed for each site. A contract was recently signed with a gypsum product end-user that will construct a wallboard facility at our Roxboro Plant. Progress Energy is working to identify beneficial uses for gypsum produced from its other FGD facilities. The Company plans to treat the scrubber wastewater stream at Asheville Plant using an innovative constructed wetland treatment system to ensure compliance with discharge limits. A similar system is being evaluated for Roxboro Plant. Discussions with various permitting divisions within DENR are ongoing.

Specific units are listed on Attachment 3 with data on projected schedules and projected annual emissions for 2009 and 2013. These projections are based on a 97% SO_2 removal efficiency, forecasted energy demand, 3.3 lbs SO2/Mbtu coal on scrubbed units, and 1.2 lbs SO2/Mbtu coal on others. Note that these are projected schedules and will be subject to revision. In 2003, foundation work began for Asheville 1 and 2 scrubbers, as well as the new common stack. Construction work also commenced at Roxboro to relocate coal handling facilities in support of upcoming scrubber and stack construction.

Particular units controlled and control technologies utilized are subject to change depending on future developments in SO_2 removal technologies, energy demand, sulfur content of coal, and other circumstances which may produce a more optimal plan for meeting the SO_2 emissions limits in 2009 and 2013. DENR will be advised as changing circumstances dictate.

Docket No. E-7, Sub 718

Dear Ms. Thigpen:

Enclosed herewith for filing in the above-referenced docket are twenty-one (21) copies of the Report of the Public Staff on Costs Incurred and Amortized by Duke Energy Corporation in Compliance with Session Law 2002-("the Clean Smokestacks Act" or "the Act"). This report presents the results of the Public Staff's review of environmental compliance costs incurred and amortized by Duke Energy pursuant to the Act through the end of calendar year 2003. The Public Staff expects to file an update to this report annually.

Sincerely,

Antoinette R. Wike

REPORT OF THE PUBLIC STAFF
ON COSTS INCURRED AND AMORTIZED BY DUKE ENERGY CORPORATION
IN COMPLIANCE WITH SESSION LAW 2002-4

FILED
MAY 03 2004
Clerk's Office
N.C. Utilities Commission

Docket No. E-7, Sub 718

May 3, 2004

Section 14 of Session Law 2002-4 ("the Clean Smokestacks Act" or "the Act") requires the Department of Environment and Natural Resources and the Utilities Commission to report by June 1 of each year, on the implementation of the Act to the Environmental Review Commission and the Joint Legislative Utility Review Committee. The May 30, 2003, report states that the Public Staff will audit the books and records of the investor owned utilities on an ongoing basis in regard to the costs incurred and amortized in compliance with the Act. The Public Staff has undertaken such a review, focusing on the verification of costs related to complying with the Act, the amortization of those costs, and contracts with vendors who will engineer and construct emission reduction equipment. This report presents the Public Staff's findings with regard to Duke Energy Corporation ("Duke Energy").

I. Work to be Performed

To comply with the emissions limitations for nitrogen oxides ("NO_X") and sulfur dioxide ("SO_2") established in the Act, Duke Energy plans to install emission reduction technologies at several of its facilities. Duke Energy has proposed to install Selective Non-catalytic Reduction ("SNCR") technology to remove NO_x and flue-gas desulfurization ("FGD") technology to remove SO_2. The facilities requiring these technologies are as follows:

Facility	NO_X Reduction	SO_2 Reduction
Allen Units 1-5	√	√
Belews Creek Units 1&2		√
Buck Units 3-6	√	
Cliffside Units 1-5	√(units 1-4 only)	√(unit 5 only)
Dan River Units 1-3	√	
Marshall Units 1-4	√	√
Riverbend Units 4-7	√	

In addition, Duke Energy is currently installing Selective Catalytic Reduction ("SCR") technology to remove NO_x from its Belews Creek and Cliffside Unit 5 facilities to comply with the North Carolina State Implementation Plan for NO_x ("NO_x SIP Call"), which is discussed below.

Duke Energy has conducted preliminary testing on the SNCR equipment at the Allen facility and the SCR equipment at Belews Creek. Such testing is normal for start-

up with new systems. Results indicated that the NO_X emissions targets at both facilities were not achieved. Duke Energy suspects that fuel quality may be the reason for the higher than expected emissions at its Allen facility, but it is still studying the problem at Belews Creek. Further testing will be conducted during the ozone season of 2004, with the results expected in late 2004. Duke Energy has expressed confidence that there is sufficient time to continue shake-down testing and achieve successful results, since the NO_x targets are not triggered until 2007.

II. Capital Costs Associated with the Installation of Emission Reduction Technologies

Duke Energy is required by the Act to report its actual capital costs ("environmental compliance costs") associated with its plan to install emission reduction technologies pursuant to the Act. Operational costs related to these emission reduction technologies are not environmental compliance costs as defined by the Act.

Duke Energy reported that its actual environmental compliance costs in calendar year 2003 were $16,041,000. The cumulative environmental compliance costs incurred through 2003 are $20,464,000, broken down as follows:

Year	2001	$ 800,000
Year	2002	3,623,000
Year	2003	16,041,000
		$20,464,000

Duke Energy's expenditures to date involve emission reduction technologies at its Allen, Belews Creek, Cliffside, Dan River, Marshall, and Riverbend facilities. Environmental compliance costs were incurred for project studies and investigations, engineering, equipment procurement, and contracting.

As part of its review, the Public Staff requested information from Duke Energy on the project costs, invoices documenting costs, and the purpose of the costs. Duke Energy provided project cost sheets delineating actual project costs by year into the following categories: (1) direct labor costs including overtime and premiums; (2) labor loads; (3) contract costs; (4) material costs; (5) overhead costs; and, (6) other costs. These costs are as follows:

Direct Labor	$ 2,075,949
Labor Loads	1,500,133
Contracts	12,020,087
Materials	3,091,897
Overheads	344,789
Other	1,430,696
	$20,463,551

The project cost sheets were supported by detailed spreadsheets that incorporated all expenditures to date for a particular category. The Public Staff selected invoices in each category from the detailed spreadsheets, and requested Duke Energy to provide specific information on the selected costs. The Public Staff also had extensive discussions with Duke personnel regarding the individual cost items charged to specific projects. Duke Energy provided sufficient documentation to support each selected cost.

Duke Energy was also requested to delineate costs related to complying with NO_X SIP Call. NO_X SIP Call requires electric utility generating facilities to reduce their emissions of NO_X during the summer ozone season, while the objective of the Clean Smokestacks Act is to reduce overall NO_X emissions for the entire year.

As a result of NO_X SIP Call, Duke Energy has undertaken a program to reconfigure its coal and air injection systems on its boiler units. In two cases, Belews Creek and Cliffside Unit 5, Duke Energy has chosen to install SCR technology to comply with NO_X SIP Call. Costs related to NO_X SIP Call are specifically exempted from the amortization allowed in Section 9 of the Act. The Public Staff has determined that Duke has not included any NO_X SIP Call related costs to date in its reported actual environmental compliance costs. However, Duke Energy may be required to install additional SCR technology on facilities where it initially plans to install SNCR technology to comply with the Act, if the SNCR technology fails to achieve the emission reduction goals set forth in the Act due to matters, such as coal quality, that are beyond the scope of Duke's contracts for work related to the Act.

III. Amortization of Costs

In Section 9 of the Act [G.S. 62-133.6(b)], the investor owned utilities are allowed to accelerate the cost recovery of their estimated environmental compliance costs over a seven-year period, beginning January 1, 2003, and ending December 31, 2009. Duke Energy's estimated environmental compliance costs are $1.5 billion. The statute requires that a minimum of 70% of the environmental compliance costs shall be amortized before December 31, 2007, when the rate freeze period expires. In Duke Energy's case, this amount is $1,050,000,000. The annual levelized amount is $214,285,714. The maximum amount that can be amortized in any given year is 150% of the annual levelized environmental compliance costs or, in Duke Energy's case, $321,428,000.

On December 11, 2003 the Commission issued an order authorizing Duke Energy to use certain regulatory liability and amortization accounts to record the environmental compliance costs associated with the Act. The Commission further ordered that no accrual of AFUDC would be allowed on any construction expenditures up to the $1.5 billion required to be amortized pursuant to the Act.

Using the protocols established by the Act and subsequent Commission orders, Duke reported that its environmental compliance costs amortization for 2003 is

$114,813,336. The Public Staff has reviewed Duke Energy's quarterly amortization filings and concluded that the reported amounts appear to be accurate.

IV. Contracts

The Public Staff also requested Duke Energy to provide for its review copies of any contracts for engineering, procurement, project management, and construction awarded to engineering firms and construction companies for the purpose of installing the emission reduction technologies. Duke Energy complied with the Public Staff's request and provided the applicable contracts.

Duke Energy has contracted with a vendor to install SNCR equipment at its Allen Steam Station. Duke Energy has elected to award separate fixed-price contracts for each project requiring emission reduction technologies to comply with the Act.

Duke Energy has also signed an alliance agreement with two vendors, creating a consortium between the companies for the installation of FGD technology, optimized specifically for Duke Energy. This agreement is a fixed price contract for each of the twelve coal-fired generation units identified by Duke Energy that require emission reduction technology to comply with the Act.

The Public Staff reviewed these contracts and determined that they contain language establishing minimum performance standards on the equipment to be installed. The contracts contain a two-year performance standard that requires the equipment to perform as designed or the vendor would be responsible for replacing, repairing, or redesigning the equipment to achieve the emission reduction target specified by Duke Energy.

V. Site Inspections

On March 9, 2004, the Public Staff conducted a site inspection of Duke Energy's Allen Steam Station in Belmont, North Carolina. Specifically, the Public Staff inspected the SNCR equipment that had been installed on the boilers and the other ancillary equipment used in the reduction of NO_X emissions from those boilers. The Public Staff confirmed the installation of the equipment and discussed the testing procedures with the plant engineer. No other facilities were inspected. It is the intent of the Public Staff to conduct inspections of other coal-fired generating facilities as Duke Energy continues to install emission reduction equipment in its boiler units.

Re: Docket No. E-2, Sub 815

Dear Ms. Thigpen:

Enclosed herewith for filing in the above-referenced docket are twenty-one (21) copies of the Report of the Public Staff on Costs Incurred and Amortized by Progress Energy Carolinas, Inc. ("PEC") in Compliance with Session Law 2002- ("the Clean Smokestacks Act" or "the Act"). This report presents the results of the Public Staff's review of environmental compliance costs incurred and amortized by PEC pursuant to the Act through the end of calendar year 2003. The Public Staff expects to file an update to this report annually.

Sincerely,

Antoinette R. Wike

REPORT OF THE PUBLIC STAFF ON COSTS INCURRED AND AMORTIZED BY PROGRESS ENERGY CAROLINAS, INC. IN COMPLIANCE WITH SESSION LAW 2002-4

Docket No. E-2, Sub 815

May 3, 2004

Section 14 of Session Law 2002-4 ("the Clean Smokestacks Act" or "the Act") requires the Department of Environment and Natural Resources and the Utilities Commission to report by June 1 of each year, on the implementation of the Act to the Environmental Review Commission and the Joint Legislative Utility Review Committee. The May 30, 2003, report states that the Public Staff will audit the books and records of the investor owned utilities on an ongoing basis in regard to the costs incurred and amortized in compliance with the Act. The Public Staff has undertaken such a review, focusing on the verification of costs related to complying with the Act, the amortization of those costs, and contracts with vendors who will engineer and construct emission reduction equipment. This report presents the Public Staff's findings with regard to Progress Energy Carolinas, Inc. ("PEC").

I. Work to be Performed

To comply with the emissions limitations for nitrogen oxides ("NO_X") and sulfur dioxide ("SO_2") established in the Act, PEC plans to install emission reduction technologies at several of its facilities. PEC has proposed to install Selective Catalytic Reduction ("SCR") technology to remove NO_x and flue-gas desulfurization ("FGD") technology to remove SO_2 to comply with the Act. The facilities requiring these technologies are as follows:

Facility	NO_X Reduction	SO_2 Reduction
Asheville Units 1&2	√(Unit 1 only)	√
Cape Fear Units 5&6		√
Lee Unit 3	√	
Mayo Unit 1		√
Roxboro Units 1-4		√
Sutton Unit 3		√

PEC is also installing SCR technology and reconfiguring its coal and air injection systems to remove NO_x from its other coal-fired generating units to comply with the North Carolina State Implementation Plan for NO_x ("NO_x SIP Call"), which is discussed below.

Although PEC initially planned to install a scrubber on Lee Unit 3, PEC indicated in its annual compliance report filed on April 1, 2004, that this work has been cancelled because projected SO_2 removal rates for scrubbed units have increased.

PEC is only in the initial design and engineering phase of construction plan, and therefore no testing data is yet available.

II. Capital Costs Associated with the Installation of Emission Reduction Technologies

PEC is required by the Act to report the actual capital costs ("environmental compliance costs") associated with its plan to install emission reduction technologies pursuant to the Act. Operational costs related to these emission reduction technologies are not environmental compliance costs as defined in the Act.

PEC reported that its actual environmental compliance costs in calendar year 2003 were $22,323,791. The cumulative environmental compliance costs incurred through 2003 are $23,209,512, as follows:

Year	2002	$ 885,721
Year	2003	22,323,791
		$23,209,512 [1]

PEC's expenditures to date involve emission reduction technologies at its Asheville, Mayo, and Roxboro facilities. Environmental compliance costs were incurred for project studies and investigations, engineering, and contracting.

As part of its review, the Public Staff requested information from PEC on the project costs, invoices documenting costs, and the purpose of the costs. PEC provided project cost sheets delineating actual project costs by year into the following categories: (1) company labor costs; (2) materials costs; (3) outside services costs; and (4) other costs. These costs are as follows:

Company Labor	$ 1,276,561
Materials	68,249
Outside Services	21,631,350
Other	233,351
Total	$23,209,511

The project cost sheet was supported by detailed spreadsheets that incorporated all expenditures to date for a particular category. The Public Staff selected invoices in each category from the detailed spreadsheets and requested PEC to provide specific

[1] PEC's estimated and reported environmental compliance costs exclude costs attributable to the portion of its Mayo and Roxboro facilities that is owned by the North Carolina Eastern Municipal Power Agency.

information on the selected costs. The Public Staff also had extensive discussions with PEC personnel regarding the individual cost items charged to specific projects. PEC provided sufficient documentation to support each selected cost.

However, the Public Staff determined that there is a discrepancy between the environmental compliance costs that are being recorded on PEC's books and the environmental compliance costs that are being reported to the Commission. The reported costs do not include labor loads or overhead costs. PEC explained that this practice is consistent with the types of costs considered to be environmental compliance costs in its estimate of $813,000,000. Typically, these costs are treated as part of project costs, whether they are considered incremental or not. The Public Staff recommends that PEC be required to file a reconciliation showing the per book and reported environmental compliance costs.

As stated above, PEC has cancelled the planned scrubber for Lee Unit 3. However, according to Appendix B to PEC's April 1, 2004, report, PEC's estimated environmental compliance costs remain approximately $813 million. Attachment I to this report shows the differences in the estimated environmental compliance costs between 2003 and 2004 according to PEC's annual reports.

PEC was also requested to delineate costs related to complying with NO_X SIP Call. NO_X SIP Call requires electric utility generating facilities to reduce its emissions of NO_X during the summer ozone season, while the objective of the Clean Smokestacks Act is to reduce overall NO_X emissions for the entire year.

As a result of NO_x SIP Call, PEC has undertaken a program to reconfigure its coal and air injection systems on its boiler units and/or install SCR technology at its Asheville 2, Cape Fear 5&6, Lee 1, Mayo 1, Roxboro 1-4, Sutton 1&3, and Weatherspoon 1-3. PEC also intends to use this equipment to achieve it emissions limitations as set forth in the Act. However, PEC will also be required to install SCR technology at its Asheville 1 and Lee 3 facilities in order to fully comply with the Act and achieve its required emissions limitations by 2007. The Public Staff has determined that PEC has not included any NO_x SIP Call related costs to date in its reported actual environmental compliance costs.

III. Amortization of Costs

In Section 9 of the Act [G.S. 62-133.6(b)], the investor owned utilities are allowed to accelerate the cost recovery of their estimated environmental compliance costs over a seven-year period, beginning January 1, 2003, and ending December 31, 2009. PEC's estimated environmental compliance costs are $813,000,000. The statute requires that a minimum of 70% of the environmental compliance costs be amortized before December 31, 2007, when the rate freeze period expires. In PEC's case, this amount is $569,100,000. The annual levelized amount is $116,142,857. The maximum amount that can be amortized in any given year is 150% of the annual levelized environmental compliance costs or, in PEC's case, $174,214,285.

On December 11, 2003, the Commission issued an order authorizing PEC to use certain regulatory liability and amortization accounts to record the environmental compliance costs associated with the Act. The Commission further ordered that no accrual of AFUDC would be allowed on any construction expenditures up to the $813,000,000 required to be amortized pursuant to the Act.

Using the protocols established by the Act and subsequent Commission orders, PEC reported that its environmental compliance costs amortization for 2003 is $74,218,804. The Public Staff has reviewed PEC's quarterly amortization filings and concluded that the reported amounts appear to be accurate.

IV. Contracts

The Public Staff also requested PEC to provide copies of any contracts for engineering, procurement, project management, and construction awarded to engineering firms and construction companies for the purpose of installing the emission reduction technologies. PEC complied with the Public Staff's request and provided the applicable contracts.

PEC has contracted with three vendors for engineering and design work, procurement of equipment, project management, and construction. PEC has elected to use one vendor for overall project management and engineering, another vendor for procurement of equipment, and a general contractor who will actually install the emission reduction technologies to comply with the Act.

PEC's agreements with its vendors are incentive-fee based contracts for all of the thirteen coal-fired generation units identified by PEC that required emission reduction technology to comply with the Act. PEC does not intend to execute separate agreements for each facility.

The Public Staff reviewed these contracts and determined that they contain language establishing minimum performance standards on the equipment to be installed. PEC's contract with its engineering and project management vendor contains a twelve-month performance guarantee from the date of functional operation. PEC's contract with its equipment vendor contains a two-year performance standard that requires the equipment to perform as designed or the vendor will be responsible for replacing or repairing the equipment to achieve the emission reduction target specified by PEC. PEC's contract with its general contractor contains a twelve-month workmanship guarantee.

V. Site Inspections

The Public Staff conducted no site inspections of any PEC facilities in connection with this audit. It is the intent of the Public Staff to conduct inspections of PEC's coal-fired generating facilities as emission reduction equipment is installed.

MEMORANDUM

TO: Environmental Management Commission
Environmental Review Commission

FROM: Keith Overcash

SUBJECT: Mercury and CO_2 Reports for Sections 12 and 13 of Clean Smokestacks Act

The **Clean Smokestacks Act (CSA)** Sections 12 and 13 require the Division of Air Quality (DAQ) to provide the Environmental Review Commission and the Environmental Management Commission with reports and recommendations annually by September relative to controls for mercury and CO_2. The attached reports constitute the second interim reports in fulfillment of these requirements.

These second interim reports are intended to add to the initial summary of the "state of knowledge" on the emissions and controls for these two substances and to define some of the options that are available for recommendations in the final reports in 2005. The 2005 drafts are planned to be available in the spring of 2005 for additional stakeholder input and discussions for final recommendations.

Significant activities continue at the federal level, which will likely be forthcoming before the final reports are due. North Carolina's decisions and actions will remain critical to the citizens of North Carolina and elsewhere. Finals reports, due by September 2005, are expected to provide the Division's and Department's more specific conclusions and recommendations reflecting developments prior to that date.

If you desire DAQ to provide any presentations, or otherwise discuss these reports, we will be available to do so. Any reactions and specific guidance for future reports would be helpful.

Division of Air Quality

REQUIREMENT FOR THIS REPORT

Excerpted from the *North Carolina Clean Smokestacks Act*

[**Title**: An Act to Improve Air Quality in the State by Imposing Limits on the Emission of Certain Pollutants from Certain Facilities that Burn Coal to Generate Electricity and to Provide for Recovery by Electric Utilities of the Costs of Achieving Compliance with Those Limits]

SECTION 12. The General Assembly anticipates that measures implemented to achieve the reductions in emissions of oxides of nitrogen (NO_x) and sulfur dioxide (SO2) required by G.S. 143-215.107D, as enacted by Section 1 of this act, will also result in significant reductions in the emissions of mercury from coal-fired generating units. The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to monitoring emissions of mercury and the development and implementation of standards and plans to implement programs to control emissions of mercury from coal-fired generating units. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of mercury. The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than 1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of mercury from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of mercury is reduced as a result of the reductions in the emissions of oxides of nitrogen (NO_x) and sulfur dioxide (SO_2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.

GENERAL ASSEMBLY OF NORTH CAROLINA - SESSION 2001 – (SENATE BILL 1078)

Ratified the 19th day of June 2002. (Ch. SL 2002-4 S.13)

Marc Basnight - President Pro Tempore of the Senate
James B. Black - Speaker of the House of Representatives
Michael F. Easley- Governor

AN INVITATION FROM SECRETARY ROSS

TO: Environmental Review Commission
Environmental Management Commission

FROM: William G. Ross, Jr.

William G. Ross, Jr.

DATE: September 1, 2004

SUBJECT: Mercury and CO_2 Reports Required by Clean Smokestacks Act

On March 23, 2004, the United States Environmental Protection Agency recognized North Carolina and the Clean Smokestacks Act for outstanding, innovative efforts in improving air quality through regulatory and policy innovations and presented our state with a Clean Air Excellence Award. I had the privilege of saying a few words at the award ceremony in Washington, D.C., on behalf of our state, Governor Easley, and all the other partners who played vital roles in the passage of the law. It was a pleasure for me to describe the story of the Clean Smokestacks Act as a story about the power of innovation, partnerships, teamwork, and leadership.

The act, in addition to providing for major reductions in SO_2 and NOx emissions from NC's 14 coal-fired power plants, directed our Division of Air Quality, over a three year period, to study and make recommendations concerning emissions of mercury and carbon dioxide.

As you know, these are important, controversial issues. For example, Donald Kennedy, the Editor of *Science*, has called climate change "the most serious issue" we face.

Last year, 2003, the Division, working with a broad group of interested parties, put together reports reviewing and summarizing the state of scientific research on mercury and carbon dioxide emissions. This year, 2004, the Division has updated the review of research, and has inventoried options for the recommendations we must make next year (2005). We now ask all interested parties to read this year's report and give us their views, questions and suggestions about it.

> In the upcoming year, as we consider what to recommend, we will evaluate options for action with a number of criteria and principles in mind. As a starting point for those criteria and principles, we plan to use ones suggested in a report of a November, 2003 Aspen Institute policy dialogue chaired by Eileen Claussen and Robert W. Fri. The title of the report is: *A Climate Policy Framework: Balancing Policy and Politics*. As adapted for use in the task that the General Assembly has given us, the criteria and principles are as follows:

1. Environmental effectiveness: How effective is the option in meeting its environmental and public health and welfare target, whether that target is public awareness, information collection and evaluation, or emission reduction?
2. Cost effectiveness: Will the option design allow cost-effective compliance? How will it affect the ability of business to compete?
3. Administrative feasibility: Can the option be administered and does it minimize administrative and transaction costs?
4. Distributional equity: Is the burden of compliance with the option fairly apportioned?
5. Political acceptability: Are there elements of option design that affect its political acceptability?
6. Technology development and diffusion: Will the option help provide a platform for technology development and diffusion?
7. Adaptability: Will the option be able to adapt to changing circumstances and incorporate new information?
8. Monitoring and counting: Will the option include things that can be monitored and are verifiable?
9. Encouraging long term success: Will the option encourage long-term progress and success?

As I mentioned above, we invite your input with respect to whether these are the appropriate criteria and principles and how the various options for recommendations come out when judged against the appropriate criteria and principles. Also, we invite you to suggest options that are not in our inventory and to tell us why such options should be considered.

In the interest of giving every citizen of our State, now and in the future, a reasonable opportunity to live a happy, healthy, and prosperous life, we solicit your input and appreciate your help.

PREFACE

The goal of this report is to present information concerning the state of knowledge for controlling mercury emissions and to begin establishing the cost/benefits relationships. This information needs to be openly considered, evaluated, discussed, and corrected where necessary. In other words, information contained in this report is anticipated to become the basis for the final report on September 1, 2005. In that report, the Department of Environmental and Natural Resources will present the Department's final findings and recommendations concerning mercury emissions from coal-fired electrical utility boilers. Stakeholders and all other interested parties are encouraged to comment on information contained in this report at their earliest convenience.

This 2004 report is based on informational updates, the three-day workshop at North Carolina State University sponsored by the Department of Environmental and Natural Resources, Stakeholders and other resources. The Department appreciates the efforts of all the workshop presenters, stakeholders and other individuals who committed their time and effort to the three-day workshop and the development of this 2004 report. This open process will continue in the development of the final report on this topic.

Portions of this document were taken directly from other government (non-copyrighted) documents in the interest of time and completeness. Some of these sections may have only minor wording changes from the original documents. Quotations are not strictly used to identify these parts, but a strong effort has been made to reference these documents and acknowledge them. The purpose has not been to claim credit for original work of others, but to provide as much detail and accuracy as possible within a limited time. Additional portions of this document have been transferred and condensed from the first interim report for document integrity.

"The greatest obstacle to discovery is not ignorance - it is the illusion of knowledge."
Daniel J. Boorstin (1914-2004)[1]

Acronyms Used In This Report

AC – Activated carbon
ACI – Activated carbon injection
ALAPCO - Association of Local Air Pollution Control Officials
CAA – Clean Air Act – Primary federal clean air statute
CAIR – Clean Air Interstate Rule
CESP – Cold-side electrostatic precipitator
CEM – Continuous Emission Measurement
COHPAC™ - Compact Hybrid Particulate Collector
CO_2 – Carbon Dioxide
CSA – NC Clean Smokestacks Act
DAQ – NC Division of Air Quality
DENR – NC Department of Environment and Natural Resources
DHHS – NC Department of Health and Human Services
DMF – Division of Marine Fisheries
DOE – U. S. Department of Energy
DWQ – Division of Water Quality
EEI - Edison Electric Institute
EMC – NC Environmental Management Commission
EPA – U. S. Environmental Protection Agency
EPRI – Electric Power Research Institute
EU/ICR- Electric Utility Steam Generating Unit Mercury Information Collection Request
FF – Fabric filter
FGD – Flue gas desulfurization
Hg - mercury
HAP – hazardous air pollutant
IAQR – Interstate Air Quality Rule
IGCC - Integrated Coal Gasification Combined Cycle
kWh – Kilowatt hour (1000 watts for one hour)
MACT – Maximum Achievable Control Technology
MW - megawatts (million watts)
NC – North Carolina
NCSU – North Carolina State University
NESHAP - national emission standards for hazardous air pollutants
NHANES –National Health and Nutrition Examination Survey
NMA - National Mining Association
NO_x – Oxides of Nitrogen, including NO_2, the primary nitrogen species from combustion.
NPR – Notice of Proposed Rulemaking
PAC – Powdered Activated Carbon
PM – Particulate matter
RGM – Reactive Gaseous Mercury
SCR – Selective Catalytic Reduction
SIP – State Implementation Plan
SNCR – Selective Non-Catalytic Reduction
SO_2 – Sulfur Dioxide
SO_3 – Sulfur Trioxide
SO_x – Oxides of Sulfur, including SO_2, the primary combustion product of sulfur
STAPPA - State and Territorial Air Pollution Program Administrators
TBtu – trillion British thermal units
TMDL – Total Maximum Daily Load

Rationale For Study Followed By Rulemaking VIII-4
Schedule VIII-4

CHAPTER I EXECUTIVE SUMMARY

This executive summary provides highlights of this 2004 interim mercury report. Chapter II discusses the human risks of mercury species in different environments. The status of state and federal legislative and regulatory action is covered in Chapter III. A discussion of various mercury control devices for use at coal-fired electrical utility boilers is found in Chapter IV. Chapter V explains the use and limitations of two existing mercury emission estimating tools. Arguments concerning the influences of local atmospheric mercury emissions are presented in Chapter VI, including findings and views concerning the Florida Everglades study. Chapter VII reports North Carolina's coal-fires utility boiler characteristics and presents a comparison of speciated mercury emissions before and after the installation of emission control equipment to control of oxides of nitrogen and sulfur dioxide. A discussion follows in Chapter VIII of three options or directions that the Division of Air Quality may take when reporting its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission by September 2005.

Methylmercury is a serious health threat to humans, particularly to unborn and young children. Mounting scientific evidence and public concern argue strongly that mercury emissions must be reduced. The mercury health concern is primarily related to the existence of methylmercury in fish, resulting in fish advisories and associated health effects. These elevated levels are caused by mercury in the environment being converted to organic mercury, primarily methylmercury, which accumulates in predatory fish. Total mercury concentrations in North Carolina's rainwater are currently above levels believed necessary to allow natural processes to restore acceptable levels of methylmercury in fish.

North Carolina is one of the leading electricity producing states with 46 coal-fired utility boilers, with a total electrical generating capacity of approximately 13,300 megawatts. These coal-fired generating units currently account for up to 66 percent of total mercury emissions estimated to be emitted into the air in North Carolina.

In response to the Clean Smokestacks Act (CSA) of 2002, Progress Energy and Duke Power are required to reduce their nitrogen oxide (NO_x) emissions 77 percent by 2009 and their sulfur dioxide (SO_2) emissions 73 percent by 2013. While the CSA addresses NO_x and SO_2, the General Assembly recognized mercury emission issues and that reducing NO_x and SO_2 from utility boilers has the co-benefit of significant mercury emission reduction. The General Assembly, through the CSA, directed the Division of Air Quality (DAQ) to study mercury emission control performance and to make recommendations as to the course of further actions needed. In response, DAQ has calculated the estimated emissions for each NC utility boiler under its current and future configuration and highlights the following emission changes from current and future mercury emissions using conventional wet scrubber technology:

- Improvement in total mercury emission removal (from pre-CSA conditions) from 33% to 64%

- Nearly two-fold decrease in total mercury emissions from 2730 to 1460 lb/yr
- Nearly five-fold drop in oxidized mercury emissions from 1810 to 380 lb/yr.

Of the three species of mercury (elemental, oxidized, and particulate), it can be argued that oxidized mercury represents the most important species to control from the State's perspective because of its tendency to be deposited within the State. This significant reduction in oxidized mercury emissions suggests the possibility of considerable reductions in mercury deposition across NC.

A dramatic drop in oxidized mercury emissions could have major implications for reduced methylmercury contamination in fish. However, the relative contribution of global versus statewide and local mercury emissions to atmospheric mercury deposition is poorly understood and remains an area of scientific debate.

DAQ's estimated mercury reduction numbers should be considered conservative. Greater mercury reductions are anticipated from improvements in scrubber efficiency. Additionally, both mercury emission estimating tools did not include effects of possible mercury oxidation by selective catalytic converters. Recent studies indicate selective catalytic converters oxidize some elemental mercury, increasing mercury capture in scrubbers.

The electrical power sector is not the only industrial sector that would need to make significant reductions. The EPA is requiring a variety of industries to meet new maximum achievable control technology (MACT) standards, which will create emission reductions of both criteria and air toxics pollutants, including mercury. In addition, various changes and trends in industry are reducing other sources of mercury to the environment in rather dramatic proportions (e.g. changes in incineration processes, changes in the metallurgical industries, recycling changes, reductions in fluorescent bulb mercury content, etc.).

There are mercury emission sources in North Carolina that are not subject to the CSA. These non-CSA mercury sources currently represent approximately 34 percent of the total 2002 mercury emissions in North Carolina. From 2005 to 2012, the installation of SO_2 controls to meet the SO_2 cap are estimated to reduce CSA mercury sources to 43 percent of the total of mercury emissions in North Carolina. Non-CSA mercury sources percentage increases to 57 percent of a greatly reduced number of pounds of mercury then expected to be emitted in North Carolina.

There are two sources of mercury deposition: the "global pool" of elemental mercury that stays in the atmosphere for a number of months or years and speciated (elemental, oxidized, and particulate) mercury emissions generated by local sources. The United States presently accounts for three to five percent of total global mercury air emissions. Experts disagree on the relative effect of mercury deposition from the global pool and deposition from local emission sources. Atmospheric mercury models are under development at several institutions around the world, with a concerted effort on model

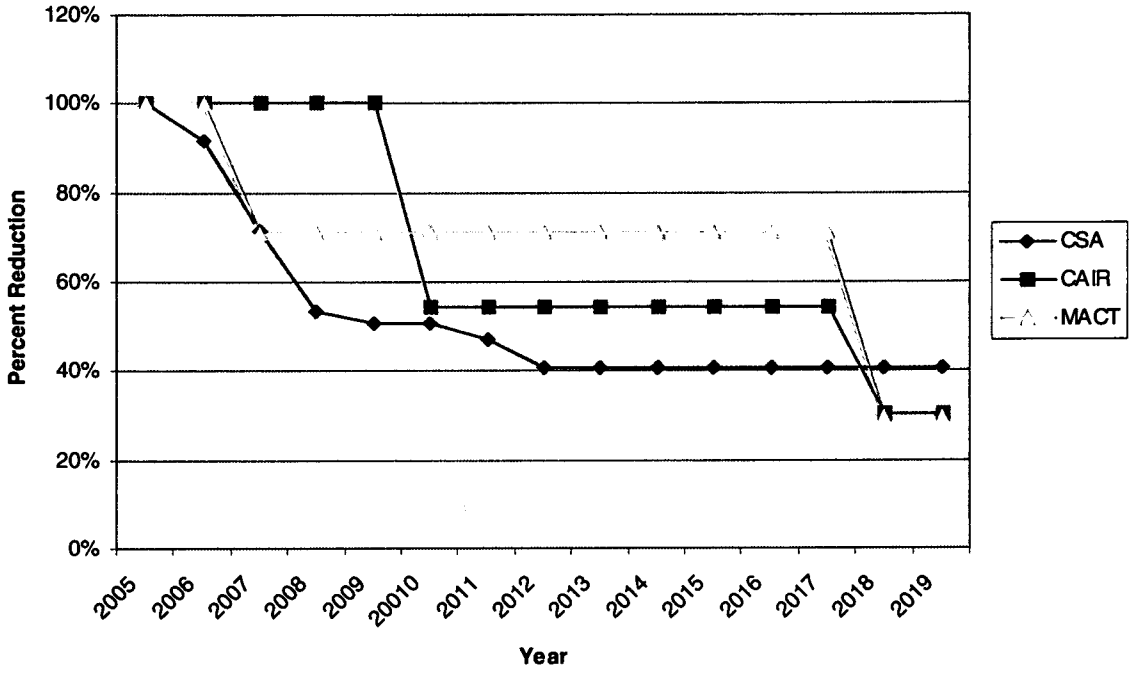
inter-comparison to identify important uncertainties in relative effects of global versus local mercury pollution.

However, at least one recently completed study indicates controlling local mercury emission sources may be important to local mercury deposition. In that study, the Florida Department of Environmental Protection examined an area of the Florida Everglades in an attempt to establish a link between airborne mercury emissions and methylmercury concentrations in top predator fish. This study provides the best example so far of the potential importance of dry deposition of mercury to total ecosystem impacts. Report findings point to a linear relationship existing between airborne mercury emissions and methylmercury concentrations in largemouth bass. The actual reduction of atmospheric sources of mercury in Florida was monitored. Since the peak deposition, monitoring showed a 60 percent decline in methylmercury in Everglades fish and wildlife in less than 15 years. The time required to achieve 50 percent of the ultimate response in fish tissue mercury concentrations is estimated to be approximately 10 years.

It is unknown if the results of this study are applicable in North Carolina as a predictive tool. South Florida's meteorology differs from that found in this State. There are also major differences in mercury sources (such as stack height and mercury emission speciation), topography, soil structure, and exposure to pollution affects across state borders. However, this study does demonstrate a strong direct correlation between decreases in mercury emissions and decreases in methylmercury in Everglade predatory fish.

The EPA has offered three approaches (proposals) to mercury emission reductions from coal-fired utility boilers. The first is to pursue traditional command-and-control of the federal Clean Air Act, section 112 MACT requirements for utility units. This proposal is estimated to reduce mercury emissions from 48 to 34 tons by January 2008. The second proposal is a cap-and-trade approach under guidelines outlined in the Clean Air Act, section 112(n)(1)(A). The third proposal involves a market-based, cap-and trade approach under section 111. The final rule is scheduled to be signed on or before March 2005.

The EPA mercury emission tool was used to estimate mercury emission reductions from the co-benefits of meeting requirements of the CSA. Credit for mercury reductions are credited for the year's planned project completion date. The following graph indicates the estimated CSA utility emissions are at or below both the proposed MACT and Clean Air Interstate Rule (CAIR) mercury reduction percentages until 2018.



The study of the complex and evolving science regarding mercury emission controls and their affects is not complete. Many (seemingly) conflicting theories on mercury chemistry and deposition exist. Within this unsettled legislative and scientific environment, DAQ is proposing three options to be considered for making specific mercury reduction recommendations in 2005.

1. Option one is to continue to study the problem and to defer any rulemaking action until a later time. The federal government, electric power industry, and pollution control industry are advancing the technology and state-of-the-science on the measurement, control, fate, and health effects of mercury emissions. The EPA is scheduled to finalize similar federal standards for controlling mercury emissions from coal-fired power plants in March 2005. The format of the federal requirements may add to the significant mercury emission reductions to be realized from the CSA. Additionally, it may be premature to accurately predict mercury emission reductions and corresponding deposition from in-state power plants resulting from co-benefits of the NOx and SO_2 control device installations that will result from the CSA.

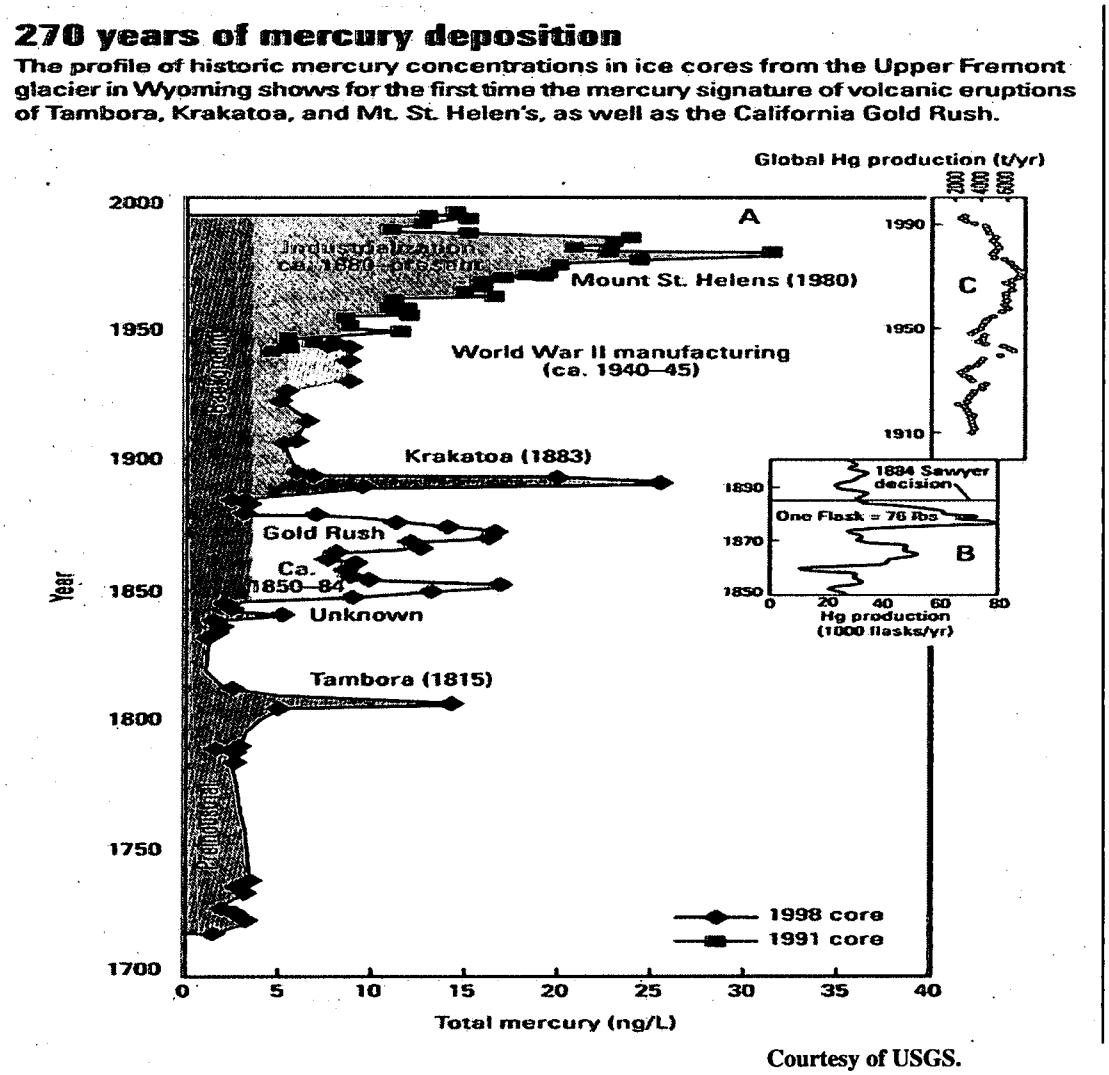
2. The second option is to follow the lead of other states and set mercury emission standards. These states take the position that, while the science and technology are not fully developed, they are adequately developed to initiate rulemaking requirements. States with mercury standards appear to be acting from the basis that, since rulemaking has a history of forcing cost-effective technological developments, rulemaking will again be the engine for development.

3. Option three is to continue the study further, and then expect to set specific mercury emission standards at a later time. Upon completion of more comprehensive studies, DAQ would recommend that the General Assembly direct the Environmental Management Commission to initiate rulemaking. This option is based on the premise that it would be beneficial for all stakeholders to wait until additional information is available for additional future mercury control than to propose standards soon that may need to be revised later.

CHAPTER II MERCURY, METHYLMERCURY, AND RISKS

The United States presently accounts for 3 to 5 percent of total global mercury air emissions. Natural sources of mercury, such as volcanic eruptions and emissions from the ocean, are estimated to contribute about 40 percent of current worldwide mercury air emissions, whereas human-made sources account for the remaining 60 percent. Figure II-1 is a graphic representation of the connection between historical events and the age of deposits in the Upper Fremont glacier in Wyoming. The growth of Industrial mercury contributions is striking.

FIGURE II-1
270 YEARS OF MERCURY DEPOSITION



Courtesy of USGS.

ATMOSPHERIC MERCURY

Mercury in the atmosphere comes both from natural sources and from global emissions from human activities. Most of the mercury in the atmosphere is elemental mercury vapor, which may circulate in the atmosphere for years ("global pool") in a dynamic deposition and re-emission state of flux, and hence, can be transported thousand of miles from the source.[2] However, modeling studies recently have suggested that the rate of oxidation of elemental mercury in the atmosphere may be occurring twice as fast (half-life of six months instead of one year) as previously believed.

Mercury transformation processes from smokestack to earth are not yet well understood. Recent experiments using plume chemistry in a static plume dilution chamber, developed by the Electric Power Research Institute, may change the interpretation of chemistry used to calculate percentages of elemental mercury and oxidized (inorganic) mercury transported in the plume. [3] This study suggests that oxidized mercury rapidly converts to elemental mercury near the stack. This finding may explain measurements made near a large coal-fired power plant in Georgia. Based on mercury concentrations in coal burned at the plant, scientists predicted that the stack gases would contain 60-percent oxidized mercury and 40 percent elemental mercury. Mercury measured in air 15 miles downwind was found to be 9 percent oxidized mercury and 91 percent elemental mercury.[3] Mercury in an oxidized form is more amenable to removal by controls on the boiler (e.g., Scrubbers) and also believed to be deposited down wind of the plant than elemental mercury.

Information presented at the workshop on Mercury and CO_2 during April 19-21, 2004 is italicized.

Update On DAQ's Air Quality Measurements & Mercury Studies[4]

NC has relatively high mercury, well above US average, in terms of:

- *Emissions into ambient air*
- *Measurements in specific ambient airsheds*
- *Modeling in specific ambient airsheds*
- *Wet deposition levels*
- *Fish of selected species*
- *People who eat selected fish species*

Power Generation Is a Major Contributor to National Air Pollutant Emissions[5]

- *SO_2: 63%*
- *NOx: 22%*

- *Hg: 37%*
- *CO_2: ~40%*

A diverse fuel mix is critical to ensure electrical reliability, minimize price volatility, and strengthen national security

MERCURY IMPACT ON LAND

Mercury modeling efforts initially made an assumption that all inorganic mercury compounds that settled on the ground would eventually enter the surface water drainage system and accumulate in rivers, streams, and lakes. Contrary to that assumption, inorganic mercury compounds have been shown to have a strong propensity to attach to and remain on leafy vegetation and soil particles. The majority of inorganic mercury compounds found in water bodies arrive directly from the atmosphere. Mercury deposited on soil and vegetation does not appear to result in exposures believed to be detrimental to health through terrestrial exposure pathways.[6]

MERCURY IMPACT IN WATER

To be converted to organic mercury, elemental mercury must first combine with another element (such as sulfur, chlorine or oxygen) or combine with other compounds to form inorganic mercury compounds, and then undergo further reactions. Recent investigations suggest that a substantial portion of what is often considered "dissolved" mercury is actually mercury associated with macromolecular colloidal organic matter (submicroscopic particles that do not settle out). Either a living organism must act on this inorganic mercury compound or an organic compound must react with it to obtain organic mercury (methylmercury) and then undergo biological interactions.

METHYLMERCURY

The main pathway of introducing methylated mercury forms into aquatic systems is mediated by sulfate-reducing bacteria. While the amount of inorganic mercury is indeed an important factor, it is not the only important factor; nor is it necessarily the controlling factor. A number of parameters have been identified as important in influencing the production rates and abundance of methylmercury in aquatic systems. They include inorganic mercury loading, chemical speciation, water temperature, the availability of an organic substrate for sulfate-reducing bacteria, mercury demethylation activity (by bacteria), natural reduction-oxidation conditions, and in some cases photo-demethylation (light induced).[7] Demethylation is the opposite action of methylation, the creation of methylmercury.

To complicate the issue further, many of these parameters vary temporally and spatially in aquatic systems. Any of these parameters can potentially limit the abundance of bio-available methylmercury in an aquatic system.[8] Demethylation eliminates the toxic

---

[6] Ref. 7, page 18.
[7] Ref. 4, page 1.
[8] Ref. 4, page 1.

methylmercury molecule. Some types of bacteria, naturally occurring reduction-oxidation chemical reactions, and light break the molecular bonds of the methylmercury molecule. Mercury methylation and demethylation are constantly taking place at the same time in the same body of water.

Two lakes that are similar biologically, physically, and chemically have been shown to have different methylmercury concentrations in water, fish, and other aquatic organisms.[9] Additional factors influence the bioaccumulation of mercury in aquatic biota. They include the acidity (pH) of the water, length of the aquatic food chain, temperature, and dissolved organic material. Physical and chemical characteristics of a watershed, such as soil type and erosion or proportion of area that is wetlands, can affect the amount of mercury that is transported from soils to water bodies. Interrelationships among these factors are poorly understood and are likely to be site-specific. No single factor has been correlated with the extent of mercury bioaccumulation in all cases examined.

FOOD CHAIN

Organic mercury, primarily methylmercury, accumulates in long-lived animals. Predatory fish at the top of the food chain accumulate increasing concentrations of methylmercury in their body tissues (bioaccumulation), which becomes a health threat to humans who eat unsafe quantities of these fish.

MERCURY IMPACT ON PEOPLE'S HEALTH

HEALTH RISKS FROM ELEMENTAL AND INORGANIC MERCURY IN AIR

The elemental and inorganic mercury that exits the smoke stack becomes part of the global pool of mercury in the atmosphere or falling on land or water. Elemental and inorganic mercury are not believed to represent major health hazards in the ambient air environment.

HEALTH RISKS FROM ELEMENTAL AND INORGANIC MERCURY IN WATER

In 1974, Congress passed the Safe Drinking Water Act. This law requires EPA to determine safe levels of chemicals in drinking water that do or may cause health problems. These non-enforceable levels, based solely on possible health risks and exposure, are called Maximum Contaminant Level Goals (MCLG). The MCLG for mercury has been set at 2 parts per billion (ppb) because EPA believes this level of exposure would not cause potential health problems.

Based on this MCLG, EPA has set an enforceable standard called a Maximum Contaminant Level (MCL). MCLs are set as close to the MCLGs as possible, considering the ability of public water systems to detect and remove contaminants using suitable treatment technologies. The MCL for total mercury in drinking water has also been set at 2 ppb because EPA believes, given present technology and resources, this is the lowest level to which water systems can reasonably be required to remove this contaminant should it occur in drinking water.

---

[9] Ref. 5, Chapter 2, page 6.

These drinking water standards and the regulations for ensuring these standards are met, are called National Primary Drinking Water Regulations. All public water supplies must abide by these regulations. EPA has found mercury to potentially cause kidney damage when people are exposed to it at levels above the MCL for relatively short periods of time.[10]

The U.S. Environmental Protection Agency (EPA) has announced the availability of a recommended fish tissue residue criterion for methylmercury to protect human health. This water quality criterion describes the maximum advisable concentration of methylmercury in freshwater and estuarine fish and shellfish tissue to protect consumers of fish and shellfish among the general population. EPA expects the criterion recommendation to be used as guidance by States, authorized Tribes, and EPA in establishing or updating water quality standards for waters of the United States. Because consumption of contaminated fish and shellfish is the primary route of human exposure to methylmercury, EPA is expressing this water quality criterion as a fish and shellfish tissue value rather than as a water column value. EPA is providing suggested approaches for relating this criterion to water column concentrations, and also plans to develop more detailed guidance to help water quality managers implement the methylmercury criterion in water pollution control programs.[11] The current EPA's recommended fish tissue residue criterion for freshwater and estuarine fish is 0.3 mg methylmercury per kilogram of fish.[12]

HEALTH RISKS FROM METHYLMERCURY IN AIR

Methylmercury is very unstable and breaks down rapidly when exposed to oxygen and sunlight. It is not believed to represent a health risk in ambient air because it is unable to exist there.

HEALTH RISKS FROM METHYLMERCURY IN WATER

Several fishing village epidemiological studies have been conducted to assess the neurodevelopment of children. Results show that the developing human nervous system to be particularly sensitive to methylmercury. The Seychelles Islands and Faroes Islands fishing village epidemiology studies of the 1980s and 1990s assessed the neurodevelopment of children from birth to several years old following maternal consumption of fish or whale meat on a routine basis during pregnancy. The Seychelles Islands are located in the Indian Ocean near Africa. The Seychelles Islands study was conducted by the University of Rochester School of Medicine and Dentistry. The Faroes Islands are located in North Atlantic between Scotland and Iceland. That study was conducted by the Harvard School of Public Health.[13]

---

[11] http://www.epa.gov/waterscience/criteria/methylmercury/factsheet.html
[12] N.C. DHHS, Occupational and Environmental Epidemiology Branch, August 5, 2004
[13] Toxicological Effects of Methylmercury, National Research Council, 2000, National Academy Press.

The Seychelles Islands study evaluated approximately 740 mother-infant pairs where the mothers consumed 12 meals per week of fish with low levels of methylmercury of less than 0.3 ppm, which is less than the North Carolina's fish advisory action level of 0.4 ppm. The mercury levels in the mothers' hair during pregnancy were on average 6.8 ppm (range 0.5 – 27 ppm). A broad range of cognitive-behavioral tests were given to the children at approximately 6 months, 1 ½ years, 2 ½ years, 5 ½ years and 9 years. No effects were detected among the children. Based on this study, maternal consumption during pregnancy of fish with low methylmercury levels (less than 0.3 ppm) is accepted as safe. [15,14,]

The Faroes Islands study evaluated approximately 700 mother-infant pairs where the mothers consumed 1-3 meals per week of fish with low levels of methylmercury (less than 0.3 ppm) and 1 meal a month of pilot whale meat containing high levels of methylmercury (1 ppm and greater), which is higher than the North Carolina's action level of 0.4 ppm. The average hair levels of the Faroes mothers during pregnancy was 4.3 ppm (range 0.2 – 39 ppm), which is similar to Seychelles. When children were evaluated at 7 years of age, researchers detected deficits in attention, language, and memory. A maternal hair level of 10 ppm, a cord blood of 58 ppb, and a daily dose of 1 microgram per kilogram per day were found to be associated with a 10 percent risk of abnormalities in language, attention, and memory in children. Based on this study, maternal consumption of seafood with high methylmercury levels may be associated with an increased risk to the developing child.[15]

According to the American Academy of Pediatrics, the differences in the results of these studies may be due to the bolus or high doses that the Faroes Islands fetuses received from maternal consumption of pilot whale meat monthly verses the low doses that the Seychelles Islands fetuses received from maternal consumption of fish weekly. Additional studies are needed to further evaluate the issue of whether the bolus doses of methylmercury that were received by the Faroes children during the sensitive time periods of development are more likely to cause neurodevelopmental damage than the same doses given cumulatively over a period of several months. The average maternal hair levels and range of maternal hair levels for these two studies were similar but the doses were delivered differently.[16]

CURRENT NCDENR WATER AND AIR SAMPLING EFFORTS

DIVISION OF WATER QUALITY

The Division of Water Quality (DWQ) has two long-term programs that monitor mercury in surface waters. These two programs, the Ambient Water Quality Monitoring Program and the Fish Tissue Monitoring Program perform assessments of total mercury on a continual basis. Additional special studies are conducted in tandem with these long-term

[14] Prenatal Methylmercury Exposure From Ocean Fish Consumption in the Seychelles Child Development Study, Myers G et al., 2003, *The Lancet* 361, pp 1686-1692

[15] EPA Mercury Report To Congress, Vol. 1 Summary, No.EPA-452/R-97-001

[16] Technical Report, *Mercury in the Environment: Implications for Pediatricians,* American Academy of Pediatrics, *Pediatrics* 108:1, pp 197-205, Goldman, l, Shanon, M, 2001.

programs in order to address specific questions or issues.

The Ambient Water Quality Monitoring Program involves the long-term water sampling of surface waters. Under this program, quarterly surface water samples are collected and analyzed for total mercury using EPA Method 245.1. With a reporting limit of 200 ng/L, this method typically identifies relatively large releases of mercury to surface waters and would not describe background or typical conditions. The DWQ chemistry laboratory is in the process of constructing a Class 1000 Clean Room in order to perform the new, low-level total mercury analytical methods described in EPA Method 1631. The DWQ expects that sample analysis will begin early 2005. With a total mercury reporting limit of 0.5 ng/L, EPA Method 1631 should allow the DWQ to determine background and typical levels of total mercury in surface waters, as well as begin to establish a database to determine trends.

The Ambient Water Quality Monitoring Program does not include the measurement of methylmercury in surface waters. Current methodology to determine methylmercury in surface waters is expensive and would require major equipment purchases for DWQ to perform the analyses.

The Fish Tissue Monitoring Program has collected thousands of fish tissue samples for mercury, and tens of thousands of fish tissue samples that includes a suite of other pollutants (e.g., PCBs, dioxin, pesticides). Since January 2000, the DWQ has processed over 800 fish tissue samples for total mercury from locations across the state. However, a majority of the samples were collected from eastern North Carolina. The DWQ continues to process up to 300 samples per year for fish tissue analysis, including total mercury. Multiple sizes and species of fish are collected and analyzed in order to provide a representation of those fish typically caught and consumed by fishermen. Presently, it is assumed that 100 percent of total mercury measured in higher trophic level fish is methylmercury (EPA 2001). This is a reasonable assumption since freshwater fish currently under advisory (i.e., bowfin, largemouth bass, chain pickerel) are high on the food chain. However, for smaller fish (e.g., sunfish), this may be an overestimation of the fraction of total mercury that is methylmercury.

In 2003, DWQ completed sampling and analysis for the Eastern Regional Mercury Study (ERMS). This study included the analysis of total mercury and methylmercury in surface water and sediment, and total mercury in fish from eastern North Carolina. Study sites tended to focus on the coastal plain physiographic region of the state (Figure II-2), however two sites were located in the piedmont. The ERMS study indicated that total mercury and methylmercury concentrations in surface water, sediment, and fish are similar to those found in other water bodies in the southern Atlantic drainage. Southern Atlantic drainage tends to have higher levels of methylmercury in surface waters than other northern and western states. The U.S. Environmental Protection Agency funded the laboratory analysis of total mercury and methylmercury.

The DWQ is currently conducting several special studies associated with mercury. This includes a special study near Riegelwood, NC (Cape Fear River Basin), additional marine

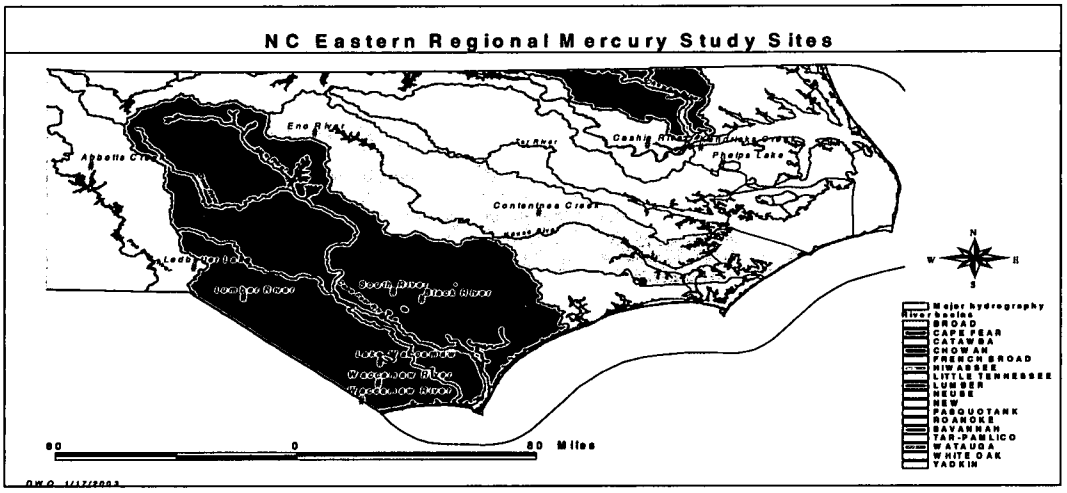
fish sampling and additional low-level mercury studies:

- The Riegelwood area monitoring study began in 2001 as a result of the closing of a chlor-alkali facility. The study seeks to evaluate the potential changes to fish tissue levels of total mercury as a result of the removal of a known atmospheric source. This study includes fish sampling and tissue analysis for total mercury at six downwind locations in the Cape Fear River Basin. Regular fish tissue sampling and analysis will continue as resources allow.

- Additional marine fish species analysis will be conducted as a joint effort between the DWQ, Division of Marine Fisheries, and the Department of Health and Human Services (DHHS). This follow-on study plans to focus on total mercury levels in spot, croaker, speckled trout, and bluefish. Additional species may be added if resources allow.

- Additional low-level mercury studies will be conducted to continue work begun in the ERMS. The additional studies will continue monitoring key DWQ-DAQ locations (i.e., Lakes Waccamaw, Lumber River Basin, and Lake Phelps, Pasquotank River Basin) and add new monitoring locations. New monitoring locations will be added to characterize total mercury and methylmercury west of the Yadkin River. The laboratory portion of this additional monitoring will be funded from a USEPA grant.

Figure II-2



DIVISION OF AIR QUALITY

The Division of Air Quality (DAQ) operates two North Carolina mercury wet (precipitation) deposition sites. The Pettigrew State Park site is located near Phelps Lake in Washington County, while the Waccamaw State Park site is stationed next to the atmospheric mercury monitoring unit near Lake Waccamaw.

Mercury levels in samples of eastern North Carolina rainwater vary widely from week to week but are comparable to data from sites across the United States. Volume-weighted average rainwater mercury levels are consistently higher at Lake Waccamaw than at a comparable site 150 miles to the north in remote northeastern North Carolina (Pettigrew State Park). Recent data from both sites during 1999 and 2000 suggests that mercury levels in precipitation may be declining in these areas. Levels declined to values typical of the more remote location at Pettigrew State Park between 1998 and 1999 at Lake Waccamaw State Park. In the years following however, the levels have crept back up. The reasons for this are definitively clear. Cleanup activities at the chlor-alkali facility have generated a considerable amount of fugitive mercury emissions. It is possible these "cleanup" emissions are to blame for the rise in mercury levels following the drop that was observed after the plant shut down in 1999. Continued sampling throughout the cleanup process and beyond should help to answer that question.

A new North Carolina mercury wet deposition measurement site is being planned. This sampling represents a joint venture by DAQ and DWQ. The existing air monitoring site is known as Condor, a CASTNET site. It is located inland from the coast in Montgomery County. The purpose of the new monitoring site is to collect background mercury concentrations. New mercury wet deposition equipment is being purchased for the site. The current schedule has valid data collection underway by late winter of 2004.

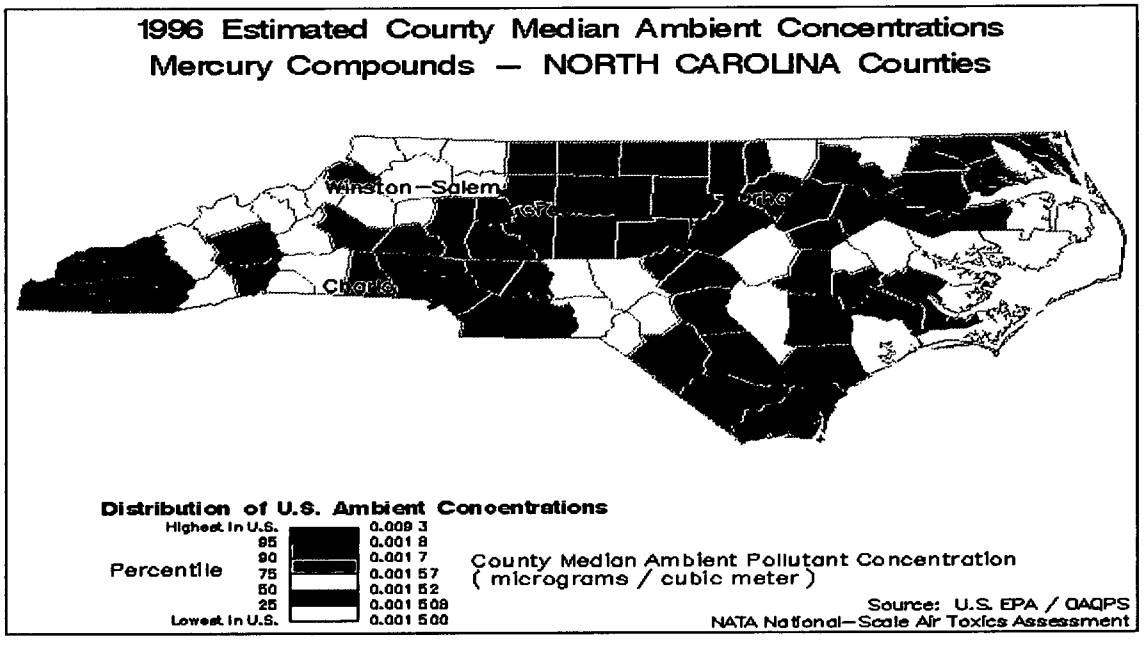
Additional DAQ mercury monitoring sites were located in the vicinity of Charlotte, North Carolina, to help define temporal and geographic trends in atmospheric mercury. To achieve this, two sampling equipment groups were operated continuously for one calendar year beginning March 2002. The first sampling site was a permanent site near the center of downtown Charlotte. Continuous data on total gaseous mercury and meteorological conditions was generated at this site. The downtown site also houses a variety of other instruments providing data for other DAQ atmospheric monitoring initiatives. It is anticipated that the data will create a snapshot of "urban" air quality conditions. Figure II-3 shows the estimated 1996 ambient mercury compound concentrations in North Carolina.

The second sampling equipment group is installed in a mobile monitoring trailer. The trailer was shared at three site locations on the perimeter of Charlotte over the course of the year. It is equipped to monitor for total gaseous mercury, reactive gaseous mercury, and elemental mercury, with the capability to also monitor for VOCs and carbonyls. These three site locations were selected to capture air quality conditions on the rapidly changing periphery of Charlotte. The final data collected are currently undergoing DAQ internal review.

At the July 30, 2004 stakeholder meeting, there was discussion about conducting a fish, air, and water sampling study to determine the mercury levels in these media before, during and after the utilities have made the CSA installments. The NC Division of Air Quality, NC Division of Public Health, NC Division of Water Quality, Duke Power, Progress Energy, Electric Power Research Institute and Research Triangle Institute could participate in the study design. Funding will be solicited to support this study. The study

length is anticipated to occur over 10-15 years. The progress of the study will be provided to the stakeholders and General Assembly on a biannual basis or sooner if needed.[17]

FIGURE II-3



NORTH CAROLINA FISH ADVISORIES

The most recent safe fish eating guidelines issued by the Department of Health and Human Services (DHHS) were prepared by the Medical Evaluation and Risk Assessment Unit (MERAU) and dated August 29, 2001. Women of childbearing age (15-44 years), pregnant women, nursing women, and children under 15 years may eat two meals per week of fish low in methylmercury, like farm-raised fish, canned tuna and other canned fish, fish sticks, shrimp, crab, lobster, clams, oysters, scallops, salmon, trout, cod, whitefish, pollock, mahi-mahi, ocean perch, halibut, haddock, flounder, croaker, herring, crappie, sunfish, white perch, yellow perch, and bream.[18] They should not eat any shark, swordfish, tilefish, or king mackerel.[19] Also, they should not eat bowfin (blackfish), chain pickerel (jack fish) or largemouth bass caught in North Carolina waters south and east of Interstate 85.

According to the guidelines, other women, men, and children over 15 years old may eat four meals per week of fish low in methylmercury, such as farm-raised fish, canned light tuna and other canned fish, fish sticks, shrimp, crab, lobster, clams, oysters, scallops, salmon, trout, cod, whitefish, pollock, mahi-mahi, ocean perch, halibut, haddock,

---

[17] N.C. DHHS, Occupational and Environmental Epidemiology Branch, August 5, 2004

[18] All fish and shellfish should be properly prepared and cooked.

[19] On January 12, 2001 EPA and FDA issued national fish consumption advisories due to high levels of mercury in some marine fish. These advisories recommend that women of childbearing age and children should not eat shark, swordfish, king mackerel or tilefish.

flounder, croaker, herring, crappie, sunfish, white perch, yellow perch, and bream.[20]. They should eat no more than one meal per week of shark, swordfish, tilefish, or king mackerel. Also, they should eat no more than one meal per week of bowfin (blackfish), chain pickerel (jack fish), or largemouth bass caught in North Carolina waters south and east of Interstate 85.

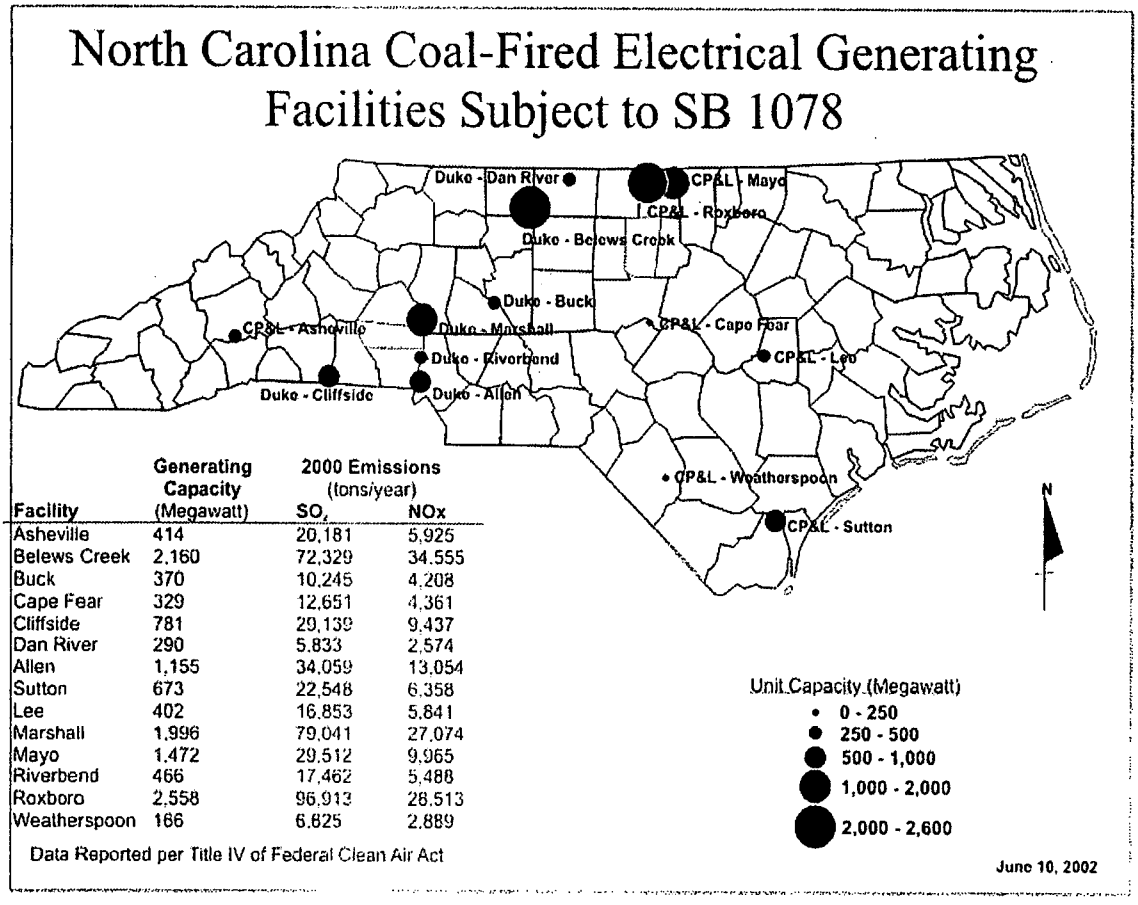
[20] All fish and shellfish should be properly prepared and cooked.

CHAPTER III LEGISLATIVE AND REGULATORY EFFORTS TO REDUCE MERCURY EMISSIONS

NORTH CAROLINA'S CLEAN SMOKESTACKS ACT (CSA)

In response to the CSA of 2002, the utility companies are required to reduce their NO_x emissions 78 percent by 2009 and their SO_2 emissions 73 percent by 2013. In order to achieve these requirements, Duke Energy and Progress Energy are in the process of installing flue gas desulfurization (FGD) wet and/or dry scrubbers to reduce SO_2 emissions, and combustion controls and post-combustion controls to lower NO_x emissions. Figure III-1 indicates the location and relative emissions of CSA boilers.

Figure III-1



Facility	Generating Capacity (Megawatt)	2000 Emissions (tons/year) SO_2	NOx
Asheville	414	20,181	5,925
Belews Creek	2,160	72,329	34,555
Buck	370	10,245	4,208
Cape Fear	329	12,651	4,361
Cliffside	781	29,139	9,437
Dan River	290	5,833	2,574
Allen	1,155	34,059	13,054
Sutton	673	22,548	6,358
Lee	402	16,853	5,841
Marshall	1,996	79,041	27,074
Mayo	1,472	29,512	9,965
Riverbend	466	17,462	5,488
Roxboro	2,558	96,913	28,513
Weatherspoon	166	6,625	2,889

CSA BOILER EMISSIONS

Coal-fired generating units currently account for approximately 66 percent of mercury emissions estimated to be emitted into the air in North Carolina. Emission control equipment planned for installation to meet the North Carolina Clean Smokestacks Act (CSA) are estimated to capture about 65 percent of mercury emissions from Duke

Power's and Progress Energy's coal-fired generating units in North Carolina by 2012.[21] Although the Act does not prescribe mercury-specific controls, these substantial mercury emission reductions are achieved as a secondary benefit (co-benefits). The proposed addition of wet scrubbers to control sulfur oxides (SO_2) is expected to reduce total mercury emissions from CSA coal-fired electrical generating units from an estimated 3,056 pounds per year (ppy) to 1,416 ppy.

Figure III-2 shows the relative percentage of each CSA affected electrical generating plant's contribution of mercury into the atmosphere in 2002 by Coal-fired boilers covered under CSA. The Roxboro, Marshall, and Belews Creek facilities combined mercury emissions are estimated to represent 60 percent of the total CSA mercury emissions.

There are mercury emission sources in North Carolina that are not subject to the CSA. A list of all sources reporting mercury emissions, including coal-fired boilers covered under CSA, was truncated with Craven County Wood Energy, who reported emissions of 6.91 pounds of mercury emissions in 2002 (see Appendix D). These non-CSA mercury sources represent approximately 34 percent (1,737 pounds) of the total 2002 (5,111 pounds) of mercury emissions in North Carolina. CSA boilers represent 66 percent (3,374 pounds). Figure III-3 graphically shows the predominance of the CSA boilers.

From 2005 to 2012, the installation of SO_2 controls to meet the SO_2 cap are estimated (EPA's Mercury Emission tool) to reduce CSA mercury sources to 43.5 percent (1,340 pounds) of the total (3,077 pounds) of mercury emissions in North Carolina. The assumption is that non-CSA mercury sources mercury discharge remains constant at 1,737 pounds of mercury per year. Figure III-3 shows that the remaining contribution of the non-CSA mercury sources percentage increases to 56.4 percent from 34 percent of a reduced number of pounds of mercury (5,111 to 3,077 pounds in 2012). Figure III-4 shows the new predominance of the non-CSA mercury sources in the State.

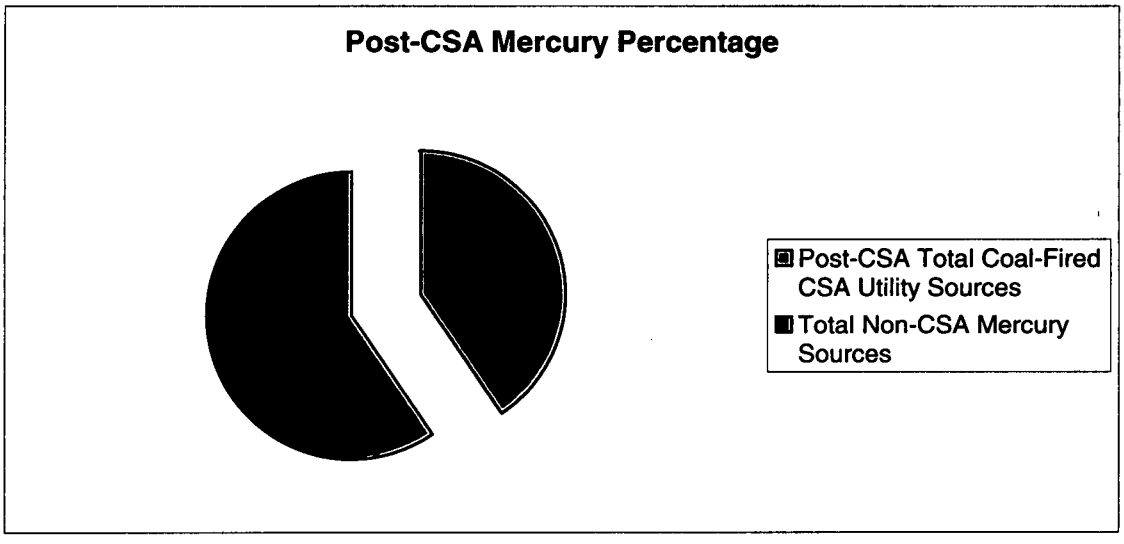
POST- CSA UTILITIES MERCURY CONTRIBUTION
43.5 PERCENT OF 3,077 LBS. MERCURY



Information presented at the workshop on Mercury and CO_2 during April 19-21, 2004 is italicized.

CURRENT AND PROJECTED MERCURY EMISSIONS[22]

- *Current Emission Estimates*

[22] New North Carolina Coal-fired Utility Multiple Pollutant Regulations,2004 Electric Utilities Environmental Conference, Tucson, AZ, January 20, 2004, Steve Schliesser, QEP, Senior Engineer, NC Division of Air Quality

a. *Uncontrolled Emissions ~ 4,100 lb/yr*

b. *Cold-side ESP Efficiency – 29%*

c. *Hot-side ESP Efficiency – 11%*

d. *Controlled Emissions ~ 3,050 lb/yr*

e. *Overall Statewide Reduction – 25%*

- *Future Emission Estimates*

a. *Cold-side ESP / FGD Efficiency – 78%*

b. *Hot-side ESP /FGD Efficiency – 39%*

c. *Controlled Emissions ~ 1,370 lb/yr*

d. *Overall Statewide Reduction– 65%*

CURRENT CSA PROGRESS BY THE UTILITIES

Progress Energy reported to the North Carolina Utility Commission on April 1, 2004, that the total project cost in future dollars remains at $813 million. The company observed that the projected SO_2 removal rates have increased for scrubbed units, resulting in a cancellation of a planned scrubber for Lee 3. Significant construction at the Asheville and Roxboro plants is taking place in 2004.

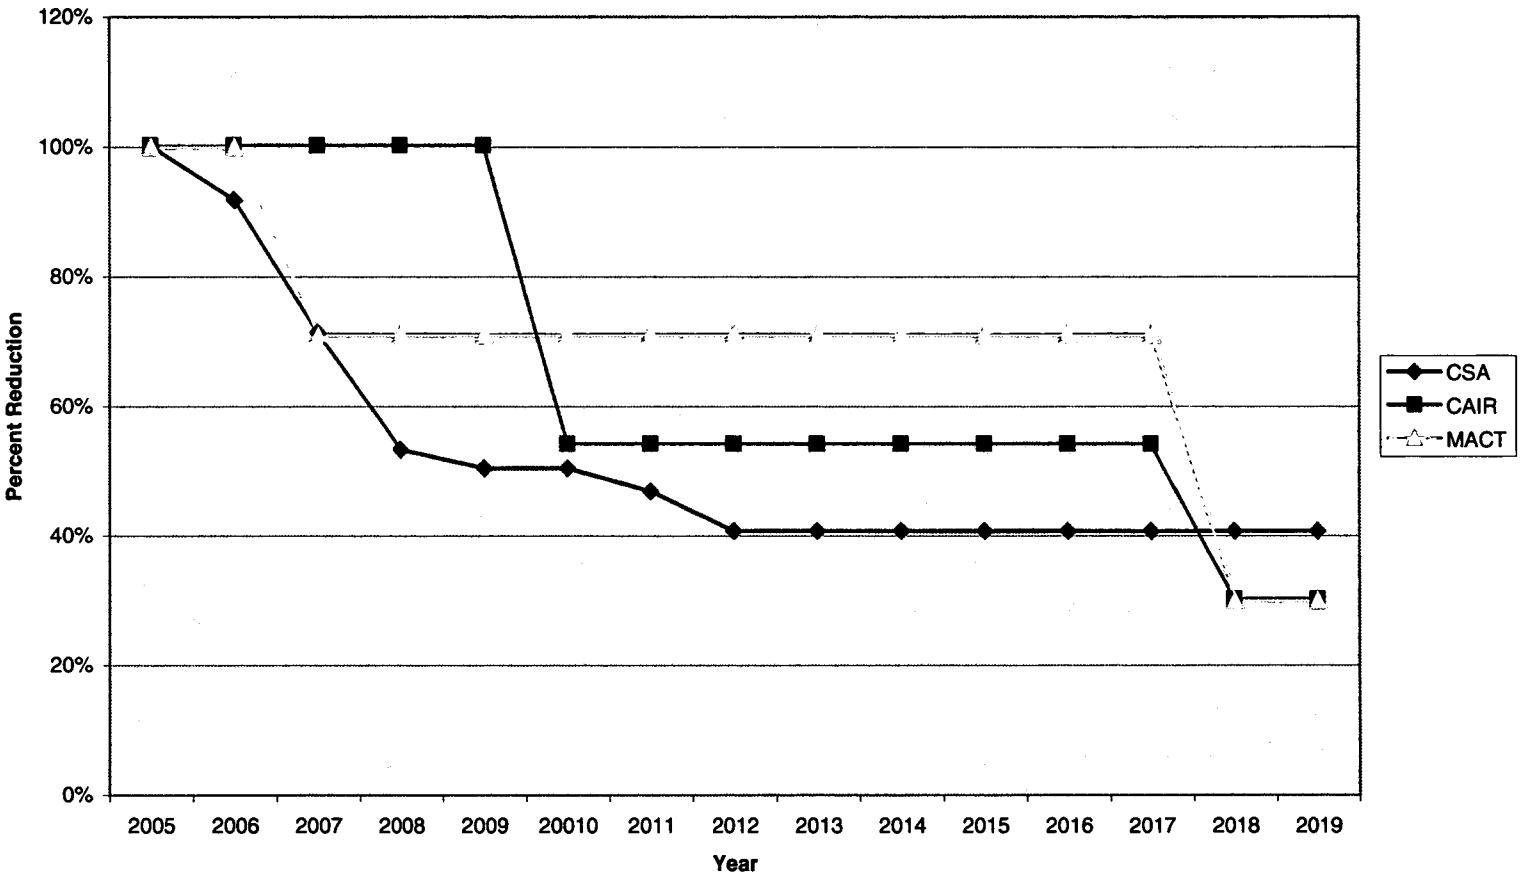
Duke Energy reported April 1, 2004, that its estimated compliance costs to be $1.526 billion. The company reported that the technologies expected to be required to support compliance have not changed.

The North Carolina Department of Environment and Natural Resources and the North Carolina Utilities Commission certified that "the actions taken to date by Progress Energy Carolinas, Inc. and Duke Power, a Division of Duke Energy Corporation, appear to be in accordance with the provisions and requirements of the Clean Smokestacks Act."[23]

The EPA Tool was used to estimate mercury emission reductions from the co-benefits of meeting requirements of the CSA. Credit for mercury reductions are credited for the year's planned completion date. Figure III-5 indicates the CSA utility emissions are at or below both the proposed MACT and Clean Air Interstate Rule (CAIR) mercury reduction percentages indicated until 2018.

[23] *The Implementation of the "Clean Smokestacks Act"*, A Report to the Environmental Review Commission and the Joint Legislative Utility Review Committee, June 1, 2004.

FIGURE III-5
COMPARISON OF CSA TO FEDERAL MACT AND CAIR PROPOSALS



CLEAN SMOKESTACKS & DUKE POWER'S MERCURY EFFORTS[24]

Power Plants in the US:

- *About 1/3 of Total US Non-Natural Emissions.*
- *About 1 % of Total Global Emissions.*
- *Mercury in coal is a "trace" element and concentrations emitted are very small.*
- *Low concentration makes control difficult.*
- *Control technologies not commercially ready. Extended run times needed to determine full impact.*
- *Inhalation of mercury from power plants is not an issue.*

Mercury types from coal combustion.

- *Elemental (Hg°), 40 to 60% (Bituminous Coal)*
- *Oxidized (HgCl), 40 to 60% (Bituminous Coal)*
- *Particulate Mercury, 0.05% Bituminous Coal)*

Co-Benefits

- *Case 1: SCR, ESP, & FGD*
- *Three Units 39% of projected system MW-hrs*
- *SCR oxidizes Hg to HgCl (80 – 90+%)*
- *Cold Side ESP 25 – 35% Hg collection*
- *FGD collects 80-90+% of oxidized Hg*
- *Expected overall Mercury removal of 80 to 90% reduction*

Duke Research:

---

[24] Mercury - Power Plants, Clean Smokestacks & Mercury Efforts, Duke Power Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

- *2001 – Collection efficiency across ESP (Marshall & Allen).*
- *2002 – Mercury oxidation with & without SCR (Cliffside 5).*
- *2004 – August: Mercury collection from pilot FGD (Marshall).*

Co-Benefits

- *Case 2: ESP, & FGD*
- *9 Units 43% of projected system MW-hrs*
- *Cold Side ESP 25 – 35% mercury collection*
- *FGD collects 50 to 60+% of remaining mercury*
- *Expected overall Mercury removal of 55 to 65% reduction*

Duke Research:

- *2005 – DOE: Pilot of oxidation catalyst downstream of ESP (Marshall).*
- *2004 – 1/04: Impact of Low NOx combustion on oxidation & ESP Collection efficiency (Marshall) – Increased oxidation & collection eff.*
- *2004 – 5/04: Verification of the impact of Low NOx combustion with different coals and unit (Allen).*

Co-Benefits *Case 3: Cold Side ESP*

- *1 Units .01% of projected system MW-hrs*
- *Cold Side ESP 25 – 35% mercury collection*

Duke Research:

- *2004 – DOE: Southern Co testing with activated carbon & impregnated carbon. Results to date 60-70% removal with activated carbon. Impregnated carbon may increase removal with less injection.*

Co-Benefits

- *Case 4: Hot Side ESP*
- *18 Units 17 % of projected system MW-hrs*

- *Hot Side ESP 0 – 9 % mercury collection*

Duke Research:

- *1999 – EPA ICR data request stack test on Cliffside 1.*
- *2003-2005 DOE: Impregnated carbon injection on Hot Side ESP.*
- *9/03 – 1 wk trial Cliffside 2*
- *Reduction: 30% full load, 70+% low load*
- *9/04 – 1 wk trial Cliffside 2 (verification of 9/03 results)*
- *2/05 – 1 month trial Buck 5*
- *Cliffside Unit 2 Hot Side ESP mercury Control, September 2003 trial.*

Continuous measurement of mercury is in the very early stage of development.

LEGISLATION TO CONTROL MERCURY EMISSIONS IN OTHER STATES[25]

The following bills were introduced in state legislatures for the 2003-2004 sessions to reduce mercury emissions and other pollutants from power plants.

Colorado – SB 140 sponsored by Senators Grossman and Williams – Requires large electrical power plants to install best available control technology by the later of 1/1/2014, or the date that is 40 years after the date on which the plant begins operation.

***Connecticut** (law) – HB6048 (Public Act 03-72) HB 6048 requires coal-fired power plants to comply with an emissions rate equal to or less than 0.6 pound of mercury per trillion BTU of heat input, or alternatively, an emissions rate comparable to a 90 percent reduction in mercury emissions. The legislation would achieve compliance through the installation of best available control technology (the act notes that if a facility installs and properly maintains the best available control technology and still fails to meet the emissions rate, it can request an alternative emissions rate from the Department of Environmental Protection

***Hawaii** – HB195 sponsored by Representative Morita - The purpose of this part is to regulate the emissions of nitrogen oxide, sulfur dioxide, mercury, and carbon dioxide by power plants, in order to protect the public health and safety and to enhance

---

[25] The National Caucus of Environmental Legislators, Compiled 2-4-04, http://www.ncel.net/news_uploads/96/Mercury.Power%20Plant%20emissions%20bills.doc,

environmental quality of life. The bill would reduce aggregate mercury emissions by an amount equal to ninety per cent from 1999 levels not later than January 1, 2007.

***Iowa** – HF435 sponsored by Representative Don Shoulz – Directs the state to set mercury emissions limits for coal fired power plants and waste incinerators by 2010.

***Maryland** – (DRAFT awaiting bill number) sponsored by Delegate James Hubbard – Sets emission limits from coal-fired power plants for nitrogen oxide, sulfur dioxide, mercury and carbon dioxide.

***Michigan** – HR187 sponsored by Representative Jack Minore - A resolution to urge the Environmental Protection Agency to reconsider and reverse its proposal to ease restrictions on mercury emissions.

***Minnesota** - HF803 sponsored by Representatives Johnson, S., Ozment, Ellison, Wagenius, Cox & SB1032 sponsored by Senators, Anderson, Pogemiller, Marty, Metzen - By July 1, 2010,an electric generation facility that uses coal as its primary fuel shall install applicable best available control technology identified by the United States Environmental Protection Agency for controlling criteria pollutants under the federal Clean Air Act, if installation of such technology is economically feasible. If installation of such technology is not economically feasible at a particular facility, the facility shall instead upgrade the facility to comply with the new source performance standards promulgated under the federal Clean Air Act applicable to a new coal-fired power plant of that type. The owner of a facility subject to this bill may opt to convert the facility to one that uses natural gas as the primary fuel to comply with that paragraph.

***New York** – AB479 sponsored by Assemblyman Pete Grannis – Directs the state to set mercury emissions limits for coal fired power plants and waste incinerators by 2010.

***New York** – AB5933 sponsored by Assemblyman Richard Brodsky - This bill requires the Department of Environmental Conservation ("DEC") to establish air pollution standards for power plants regarding nitrogen oxide, sulfur dioxide, carbon dioxide and mercury. Requires the commissioner to promulgate emergency regulations within thirty days such that electric generators of a 15MW capacity or more shall emit no more than 1.5 pounds per MW hour of Nitrogen oxide (NO_x) by 2004 and no more than 3 pounds per MW hour of sulfur dioxide (SO_2) by 2007. Requires the department to promulgate regulations for reductions in emissions of carbon dioxide and establish a cap by January 1, 2007, that is 7 percent less than the total 1990 CO_2 emissions. Requires the department to promulgate regulations for reduction in emissions of mercury from electric generators that is no more than 10 percent of the mercury emissions generated in 1999 by January 1, 2007.

***New York** – SB3172 sponsored by Senator Eric Schneiderman – This bill directs the state to set regulations reducing power plant emission of NO_x, SOx, CO_2 and mercury. The bill calls for a 90 percent reduction in mercury emissions.

Virginia – HB1472 sponsored by Representative Jack Reid - Establishes a schedule by which investor-owned public utilities that own or operate coal-fired generating units are required to reduce by specific amounts their emissions of oxides of nitrogen, sulfur dioxide and mercury. The utilities are to determine what technologies will be used to achieve the emission limits established by the bill. Any permit issued by the Air Pollution Control Board for a coal-fired generating unit, which is subject to this new law, will have to provide for testing, monitoring, record keeping and reporting to assure compliance with the reduction requirements. The bill also authorizes the Governor to enter into agreements with the utilities to transfer to the state any emissions allowance that may be acquired by the utilities under federal law. The Department of Environmental Quality and the State Corporation Commission (SCC) are to report annually to the status of the emissions reduction and cost recovery efforts to the committees having jurisdiction over the subject matter. In addition, the Department of Environmental Quality is required to conduct an ongoing analysis of the issues related to the development and implementation of standards and plans to control carbon dioxide (CO_2) from coal-fired generating units. The Department is also to evaluate available control technologies and perform a cost-benefit analysis of alternative strategies to reduce emissions of CO_2, and report its findings to the committees with jurisdiction

***Washington** - SB582 sponsored by Senator Keiser, Fraser and Kline – Requires the state to develop a toxic air emissions strategy that includes: 1) establishing a ten-year schedule to adopt emission reduction standards that significantly reduce emissions for the top ten toxic air pollutants and 2) undertaking actions, including any necessary rule making, to begin emission reductions for the six toxic air pollutants posing the greatest relative risk, as determined by the department, no later than January 1, 2006.

***Wisconsin** – On February 4, state legislators will request that the DNR reintroduce rules seeking an 80 percent reduction in mercury emissions by 2018. The rules were rejected by a legislative committee last December and were being held in limbo by the DNR Board, a group that has oversight over the DNR.

Other States' Actions

Massachusetts – On September 19, 2003, Governor Mitt Romney announced regulations that will require the state's oldest power plants to significantly reduce mercury emissions. The Executive Office of Environmental Affairs (EOEA) and the Massachusetts Department of Environmental Protection (DEP) have proposed a two-phase mercury emissions standard. The first phase requires facilities to capture 85 percent of the mercury contained in combusted coal by October 1, 2006. The second phase requires facilities to capture 95 percent of the mercury by October 1, 2012. In total, the regulations will cut mercury emissions by over 130 pounds per year. (Source: Massachusetts Dept. of Enviro. Protection news release, 9/13/03; http://www.state.ma.us/dep/pao/news/mercregs.htm)

***New Hampshire** – In 2002, New Hampshire passed the nation's first 4-pollutant law requiring reductions in NO_x, SO_2, CO_2, and mercury. The law requires an annual cap applicable to total mercury emissions from all affected sources burning coal as a fuel, to be recommended by the department not more than 60 days following the U.S.

Environmental Protection Agency's proposed regulation establishing a Maximum Achievable Control Technology (MACT) standard for mercury emissions from utility boilers, but in no case later than March 31, 2004, with timely consideration by the legislature expected by July 1, 2005. (Source: HB284 sponsored by Rep. Jeb Bradley)

*Sponsored or co-sponsored by a participant in the National Caucus of Environmental Legislators.

FEDERAL ACTIONS AND STATUS

In the January 30, 2004 Federal Register, EPA proposed new air rules for reducing emissions of sulfur dioxide (SO_2), nitrogen oxides (NO_x), and mercury. EPA proposed the Interstate Air Quality Rule, which focuses on states whose SO_2 and NO_x emissions are significantly contributing to fine particle and ozone pollution problems in other downwind states. The proposed Interstate Air Quality Rule would cover 29 states in the Eastern United States and the District of Columbia. In a separate but closely related action, EPA proposed the Utility Mercury Reduction Rule for controlling mercury emissions from power plants. Together, the Interstate Air Quality Rule proposal and mercury proposal create a multi-pollutant strategy to improve air quality throughout the U.S.[26]

INTERSTATE AIR QUALITY RULE[27]

EPA Administrator Mike Leavitt signed the proposed Interstate Air Quality Rule on December 17, 2003. The proposed Interstate Air Quality Rule would reduce emissions of SO_2 and NO_x in 29 eastern states and the District of Columbia in two phases. SO2 emissions would be reduced by 3.6 million tons in 2010 (approximately 40 percent below current levels) and by another 2 million tons per year when the rules are fully implemented (approximately 70 percent below current levels). NO_x emissions would be cut by 1.5 million tons in 2010 and 1.8 million tons annually in 2015 (about 65 percent below today's levels).

Each affected state would be required to revise its state implementation plan to include control measures to meet specific statewide emission reduction requirements. To achieve the required reductions in the most cost effective way, the proposal suggests that states regulate power plants under a cap and trade program similar to EPA's highly successful Acid Rain Program. Emissions would be permanently capped and could not increase.

CLEAN AIR INTERSTATE RULE (CAIR)[28]

On May 18, 2004, the Environmental Protection Agency proposed additional details and rule text supplementing its January 2004 proposal (and renaming it) to reduce interstate transport of fine particulate matter and ozone. The CAIR would require 29 eastern states and the District of Columbia to significantly reduce and permanently cap emissions of sulfur dioxide (SO_2) and/or nitrogen oxides (NO_x). In 2015, NO_x emissions from the

[26] http://www.epa.gov/oar/interstateairquality/

[27] http://www.epa.gov/oar/interstateairquality/basic.html

[28] http://www.epa.gov/oar/interstateairquality/pdfs/cairsuppfs51804final.pdf, Supplemental Proposal for Reducing Interstate Transport of Fine Particulate Matter and Ozone.

power sector would be 65 percent below today's levels. SO2 emissions from that sector would be 50 percent below current levels by 2015 and approximately 70 percent below current levels when fully implemented.

Reducing emissions of these pollutants will significantly address these health issues, in addition to improving visibility and protecting sensitive ecosystems. EPA's modeling predicts that when combined with existing emissions reduction requirements, this rule would help approximately 90 percent of "nonattainment areas" meet national air quality standards for ozone and particle pollution.

By addressing air pollutants from electric utilities in a cost-effective fashion, EPA's Clean Air Interstate Rule proposal would protect public health and the environment without interfering with the steady flow of affordable energy for American consumers and businesses. Each of the 29 states affected by the program and the District of Columbia must submit a plan to EPA that demonstrates it will meet its assigned statewide SO_2 and/or NO_x emissions budget (i.e., emissions reduction requirements). States can meet the emissions reduction requirements by either: joining the EPA-managed cap-and-trade programs for power plants, or achieving reductions through other emissions control measures.

UPDATE ON MACT PROPOSAL[29]

The proposed new proposed rulemaking (NPR) Clean Air Act (CAA), section 112 MACT rule would limit emissions of mercury from coal-fired EGUs and Ni from oil-fired EGUs. Exposure to mercury or nickel above identified thresholds has been demonstrated to cause a variety of adverse health effects. The NPR also proposed an alternative to regulate mercury from coal-fired EGUs and Ni from oil-fired EGUs under Section 111. In the January 30, 2004 NPR, EPA also proposed, in the alternative, standards of performance under CAA section 111 to establish a mechanism by which mercury emissions from new and existing coal-fired Utility Units would be capped at specified, nation-wide levels. A first phase cap would become effective in 2010 and a second phase cap would become effective in 2018. Facilities would demonstrate compliance with the standard by holding one ''allowance'' for each ounce of mercury emitted in any given year.

DESCRIPTION OF MERCURY EMISSION CREDIT TRADING RULE PROPOSAL

Allowances would be readily transferrable among all regulated facilities. EPA believes that such a ''cap and trade'' approach to limiting mercury emissions is the most cost effective way to achieve the reductions in mercury emissions from the power sector that are needed to protect human health and the environment. The added benefit of this cap-and trade approach is that it dovetails well with the sulfur dioxide (SO_2) and nitrogen oxides (NO_x) Interstate Air Quality Rule (IAQR) that was also proposed through a notice January 30, 2004 (69 FR 4565). That proposed rule would establish a broadly applicable Federal Actions and Status.

---

[29] Federal Register / Vol. 69, No. 51 / Tuesday, March 16, 2004 / Proposed Rules

In the January 30, 2004 Federal Register, EPA proposed new air rules for reducing emissions of SO_2, nitrogen oxides NO_x, and mercury. EPA proposed the Interstate Air Quality Rule, which focuses on states whose SO_2 and NO_x emissions are significantly contributing to fine particle and ozone pollution problems in other downwind states. The proposed Interstate Air Quality Rule would cover 29 states in the Eastern United States and the District of Columbia. In a separate but closely related action, EPA proposed the Utility Mercury Reduction Rule for controlling mercury emissions from power plants. Together, the Interstate Air Quality Rule proposal and mercury proposal create a multi-pollutant strategy to improve air quality throughout the U.S.[30]

REDUCING POWER PLANT EMISSIONS: EPA'S NEW PROPOSED RULES FOR MERCURY[31]

EPA Proposes to Reduce Utility Emissions through Current Clean Air Act (CAA) Authorities

1. *Interstate Air Quality Rule (IAQR) to address the contribution of transported SO_2/NO_x emissions to ozone (smog) and fine particle ($PM_{2.5}$) nonattainment problems in the Eastern U.S.*

Standards to Reduce Mercury Emissions and Deposition

1. *Section 112 standards*
   - *Maximum achievable control technology (MACT)*
   - *Command-and-control*
   - *Take comment on trading options*

2. *State-implemented section 111 standards*
   - *Emissions Guidelines and New Source Performance Standards*
   - *Market-based, cap-and-trade program*

Proposed Alternatives to Reduce Mercury Emissions from the Power Sector

- *Three individual approaches outlined in the January 30, 2004 proposal*

  1. *Propose traditional, command-and-control section 112 MACT requirements for utility units. Reduces mercury emissions from 48 to 34 tons by January 2008*

  2. *Propose cap-and-trade approach under guidelines outlined in section 112(n)(1)(A)*

---

[30] http://www.epa.gov/oar/interstateairquality/

[31] Reducing Power Plant Emissions: EPA's New Proposed Rules For Mercury, William H. Maxwell, Combustion Group, U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Research Triangle Park, North Carolina, Workshop on Mercury and CO2, Raleigh, NC, April 19-21, 2004

3. *Propose market-based, cap-and trade approach under section 111*

   a. *Revises December 20, 2000 finding that it is "appropriate and necessary" to regulate Utility Units under section 112*

   b. *Caps mercury emissions at 15 tons in 2018; interim cap for 2010 proposed to encourage early reductions in SO_2 and NO_x, generating additional mercury emissions reductions*

   c. *Final approach to be determined following completion of public hearings and close of public comment period*

Final rule signed on/before March 2005

SECTION 112 MACT

A. *Affected source definition*

1. *Electric Utility Steam Generating Unit (Utility Unit)*

   a. *Any fossil fuel-fired combustion unit of more than 25 MWe that serves a generator that produces electricity for sale*

   - *Cogeneration Utility Unit – unit that generates steam and electricity and supplies more than one-third of its potential electric output capacity and more than 25 MWe output to any utility power distribution system for sale*

   - *Cogeneration is defined as the simultaneous production of power (electricity) and another form of useful thermal energy (usually steam or hot water) from a single fuel-consuming process*

2. *Non-Utility Units, not subject to this rule*

   - *Any unit that meets the above definition, <u>but</u> combusts natural gas >98% of the time*

   - *Simple- and combined-cycle turbine units*

   - *Industrial boilers*

SECTION 111(D) – EMISSION GUIDELINES (EG)

1. *Requires EPA to prescribe regulations that outline a procedure by which each State shall submit plans which create standards of performance for existing sources for which air quality criteria have not been set but for which NSPS have been established.*

2. *Cap-and-Trade program reduces the overall amount of emissions by:*
   - *Requiring sources to hold allowances to cover their emissions on a one-for-one basis*
   - *Limiting overall allowances so that they cannot exceed specified levels (i.e., the "cap level"*
   - *Reducing the cap to less than the amount of emissions actually emitted, or allowed to be emitted, at the inception of the program*
   - *Allowing for a declining cap over time*
   - *Creating market-based incentives for early reductions*

SECTION 111 – REGULATORY APPROACH

1. *Primary goal is to reduce Utility Unit mercury emissions from current levels*
   - *2018 cap is permanent*

2. *Effectively becoming more stringent as more plants are required to keep their collective emissions below 15 tons*
   - *Near-term interim cap in 2010*

3. *Level will reflect the maximum level of mercury reductions achievable through FGD and SCR installations (for SO_2 and NO_X emission reductions) on units covered under the IAQR*

4. *Level is not prescribed in current proposal because of uncertainties associated with the ability of these controls to reduce mercury emissions*

5. *EPA seeks comment and technical information on the Phase I cap level*

6. *EPA believes that a carefully designed "multi-pollutant" approach – a program designed to control NO_X, SO_2, and mercury at the same time – is the most effective way to reduce emissions from the electric power sector*

Details of section 111 trading program are outlined in a Supplemental Notice of Proposed Rulemaking (SNPR), which was published on March 16, 2004

SNPR: MERCURY PROGRAM REQUIREMENTS UNDER SECTION 111

1. *Each State must submit a plan that demonstrates it will meet its assigned statewide mercury emissions budget*

    a. *States may join the trading program by adopting or referencing the model trading rule in State regulations; or, adopting regulations that mirror the necessary components of the model trading rule*

    b. *States can choose not to join the federal trading program and meet their budget through intra-state trading or no trading*

    c. *States can also choose to implement more stringent mercury emissions requirements*

2. *EPA has taken comment on a proposal to promulgate, under section 112(n)(1)(A), a cap-and-trade program for mercury from coal-fired utility units*

    a. *Trading program would be federally implemented with the EPA, instead of states, serving as the permitting authority*

SNPR: MONITORING MERCURY EMISSIONS

1. *Monitoring of mercury will resemble current monitoring of SO_2 and NO_x under the Acid Rain and NO_x SIP Call programs*

2. *A comprehensive QA/QC program ensures the adequacy of emissions data*

3. *Current monitoring in the Acid Rain and NO_x SIP Call programs averages over 98% availability*

4. *A petition process enables monitoring flexibility and facilitates the resolution of issues*

5. *Commensurate with the SO_2 and NO_x cap-and-trade programs, regulated sources would have the flexibility of using alternative monitoring approaches as long as such approaches meet the performance requirements in the rule*

SUMMARY

1. *Recent proposals are based on 3 major points regarding public health*

   - *Science continues to tell us to move aggressively on fine particles*
   - *There is growing evidence that ozone may be a larger problem than previously expected*
   - *Mounting scientific evidence and public concern/interest indicate that mercury emissions must be controlled*

2. *Administration strongly prefers the Clear Skies Act legislation instead of controlling NO_x, SO_2 and Hg under the existing CAA*

   - *EPA will stay with the current package of proposals, absent any movement on the legislation*
   - *EPA is committed to action*

3. *Power sector is not the only industrial sector EPA is looking towards to make significant reductions*

   - *Petroleum refining, car/truck/engine manufacturing, and construction equipment industries are making reductions through the Tier II, Heavy Duty Diesel, and Non-road Diesel rules*
   - *EPA is also requiring a variety of industries to meet new MACT standards, which will create emission reductions of both criteria and air toxics pollutants*

NEXT STEPS

Finalize Mercury Rule	*December 2004*
Finalize Interstate Air Quality Rule	*December 2004*

PROPOSED UTILITY MACT MERCURY EMISSION LIMITS[32]

	New Unit		*Existing Unit*	
Coal Rank	*10^{-6} lb/MWh*	*or lb/TBtu*	*10^{-6} lb/MWh*	*or lb/TBtu*
Bituminous	*6*	*0.57*	*21*	*2.0*
Subbituminous	*20*	*1.90*	*61*	*5.8*
Lignite-Fired	*62*	*5.82*	*98*	*9.2*

[32] Summary of Proposed Regulations: Mercury, Paul Farber, Sargent & Lundy, LLC Chicago, IL, Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

IGCC Unit	*20*	*1.90*	*200*	*19*
Coal Refuse	*1.1*	*0.102*	*4.1*	*0.38*

Note: Emission limits for new units are proposed in 10^{-6} lb/MWh units only (12-month rolling average).
Equivalent lb/TBtu limits are provided for reference.
Existing units have the option of complying with either the lb/TBtu or lb/MWh emission limit.

INSIGHTS ON ECONOMIC IMPACTS OF UTILITY MERCURY AND CO_2 CONTROLS[33]

Mercury trading is very cost-effective compared to mercury unit-specific targets

EPA's proposed MACT would cost 5-10 times more than its proposed mercury Cap on NPV basis:

- *Mercury trading is far more cost-effective*
- *MACT achieves ~32 tons by 2008*
- *Mercury Cap achieves 15 tons by 2020 (32 tons at ~2012)*

Cost-effectiveness advantages of proposed trading rule would be heightened by technical improvements in mercury control options:

- *Timing flexibility gives opportunities for technology to improve before it must be implemented broadly.*
- *Trading "places a price" on mercury emissions which also incentivizes technical improvements better than MACT.*
- *Mercury trading tends to concentrate reductions on the largest sources.*

OTHER OPINIONS CONCERNING THE CONTROL OF MERCURY EMISSIONS

EDISON ELECTRIC INSTITUTE

In comments by Edison Electric Institute (EEI) to Environmental protection agency in response to 40 CFR Parts 60 and 63, Proposed National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units; Proposed Rule 40 CFR Parts 60, 72, and 75 Supplemental Notice for the Proposed National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility

[33] Insights on Economic Impacts of Utility Mercury and CO2 Controls, Anne Smith Charles River Associates, North Carolina DENR/DAQ Workshop on Mercury and CO2, Raleigh, NC, April 19-21, 2004

Steam Generating Units; Proposed Rule, June 29, 2004, the following major points were addressed:[34]

- EEI believes that, despite dramatic decreases in emissions from the electric generating sector in recent decades, further cost-effective reductions in emissions may be achieved under the proper framework, especially under a properly designed national cap-and-trade program.

- Legislation provides greater certainty for business and the environment, while regulation generally fails to address the overlapping nature of more than a dozen existing interconnected air programs.

- There are inconsistencies in the proposed rule. The preamble states that a unit is considered to be an oil-fired unit and subject to the nickel MACT if it is equipped to fire oil and/or natural gas, and if "it fires oil in amounts greater than or equal to two percent of its annual fuel consumption." However, the same preamble states that the nickel MACT would not apply to units that combust natural gas "greater than 98 percent of the time."

- Integrate and streamline these programs if the mercury rule is to achieve the desired emission reductions at reasonable cost to the American consumer. A cap-and-trade approach is the best way to reduce emissions from the electric utility industry. Such a rule would be protective of public health, scientifically sound, flexible, and cost-effective – all components of reasonable and sensible public policy.

- EPA should establish subcategories for the source category of electric utility steam generating units. Fluidized bed combustion units should be in a separate category and Integrated Gas Combined Cycle (IGCC) units should be exempt. Conventional boilers must be subcategorized by coal rank (bituminous, subbituminous and lignite); other considerations could include process differences and coal chemistry for further subcategorization.

- MACT floors for subcategories must account for the inherent variability in mercury emissions from the best performing units. There are numerous methods for addressing variability, and more than one approach may be necessary to account for variability related to fuel and variability related to plant operations.

- There is currently no justification for regulation beyond the MACT floor.

- There should be no additional requirements beyond what is required to meet the MACT floor for existing units and to satisfy NSPS requirements.

[34] http://www.eei.org/about_EEI/advocacy_activities/Environmental_Protection_Agency/EEI_mercury_final_040629.pdf

- There should be a choice between the least stringent of either a percent reduction standard (percent mercury removed as difference between mercury in coal and mercury emitted from stack) or input-based emission rate (stack concentration in lb/TBTU) standard.

ENVIRONMENTAL DEFENSE

Environmental Defense Recommends: [35]

- Reducing power plant pollution is critical to lowering local mercury deposition and avoiding the dangerous contamination of fish, wildlife and people.

- The EPA should issue strong mercury standards for power plants to reduce mercury pollution from 48 tons today to about 5 tons, or a 90 percent reduction. These reductions are consistent with national standards for other source sectors and achievable through available pollution-control technology.

- States with mercury deposition hot spots should pursue their own mercury pollution standards to protect local water bodies and public health, and all states should press for rigorous national standards.

THE NATIONAL MINING ASSOCIATION

Mr. Jack Gerard, president and CEO of the National Mining Association (NMA), said that after studying the Environmental Protection Agency's emissions data, NMA concludes that EPA's statistical analysis, sampling and methodology are inadequate for determining mercury reduction values for any coal type and for setting emissions limits. "In the absence of adequate emissions data for the wide variety of US coal types and power plants, and without demonstrated technologies for reducing mercury emissions, EPA cannot implement an effective MACT [maximum achievable control technology] rule for power plants, nor set accurate emissions allowances for a cap-and-trade program," Gerard went on to say that EPA's data represents at best only a partial snapshot of the industry. "We don't think it's wise to base decisions that will have far-reaching economic implications on inadequate data that reflect neither the differences among coal types nor the differences among power plant operations," NMA suggestions for mercury proposals include:

- A modification of EPA's cap-and-trade proposal that would allow for greater certainty in setting achievable emissions reductions. Under this proposal, hard data from actual mercury reductions achieved under EPA's new interstate air quality rule would lead to a fairer allocation of emissions allowances for coal types, allow for a more thorough assessment of

[35] http://www.environmentaldefense.org/documents/3370_MercuryPowerPlants.pdf

mercury abatement technologies commercially available, and form the basis of interim emissions allowances in 2015.

- New units should not be forced to rely on purchased credits alone for meeting emissions targets, but should be granted modest allowances to minimize the possibility that power plants would switch to more costly fuels and raise energy costs further.

- NMA suggests that banking of emissions credits be deferred until 2015, stating the later date would better ensure that target reductions in 2018 would be achieved without heavy use of credits banked throughout the longer, eight-year period proposed by EPA.

STAPPA/ALAPCO ORGANIZATION

The State and Territorial Air Pollution Program Administrators (STAPPA) and the Association of Local Air Pollution Control Officials (ALAPCO) are the two national associations representing air pollution control agencies in 54 states and territories and over 165 major metropolitan areas across the United States. State and local air pollution control officials formed STAPPA and ALAPCO over 30 years ago to improve their effectiveness as managers of air quality programs. The associations serve to encourage the exchange of information among air pollution control officials, to enhance communication and cooperation among federal, state and local regulatory agencies, and to promote good management of our air resources.

With respect to mercury, STAPPA and ALAPCO based their analysis on state actions to reduce mercury emissions. State mercury limits proposed or adopted in Connecticut, Massachusetts and New Jersey will achieve control efficiencies on the order of 90 percent or more, while in Wisconsin, where mostly western coal is used, limits are 80 percent. Accordingly, STAPPA and ALAPCO extrapolated such reductions nationwide and arrived at a recommended national mercury emission cap range of 5 to 10 tons per year by 2013; such a range accommodates both eastern and western coal. Further, this range is consistent with STAPPA and ALAPCO's October 2002 recommendation to the EPA Utility MACT Working Group, which, if implemented nationwide, would result in mercury emissions of less than 7.5 tons per year.

The associations also identified a range for an interim mercury emission cap of 15 to 20 tons per year, to be achieved by 2008. Mercury levels in this interim cap range they project to be should be largely achievable through the application of the same air pollution control equipment needed to achieve compliance with the interim NO_x and SO_2 caps that STAPPA and ALAPCO have identified in this analysis. Traditional control technologies for criteria pollutants have been shown to be effective for mercury reduction, especially when used in combination; the most effective for mercury is a combination of low-NO_x burner, selective catalytic reduction, baghouse and scrubber technologies. This interim cap range is also intended to encourage the use of mercury specific control technologies, such as activated carbon injection (ACI), by some facilities. ACI has low capital cost, especially with an existing baghouse, has been proven on

incinerators, and has been piloted and demonstrated and is currently available for coal. The 20-ton-per-year level results if mercury reductions are achieved in the same proportion as NO_x and SO_2 reductions under the recommended interim caps for those pollutants. The 15-tonper-year level reflects a desire to be more progressive in controlling mercury, because it is a hazardous air pollutant. Approximately twice the level that STAPPA and ALAPCO recommended for MACT, a 15-ton-per-year level for mercury is appropriate in the context of a harmonized strategy addressing multiple pollutants.[36]

On June 29, 2004, STAPPA and ALAPCO addressed problems they found with the "National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units: Proposed Rule," A copy of the letter is in Appendix B of this report. Primary concerns as cited in their letter include:

- STAPPA and ALAPCO are extremely dismayed with EPA's proposals to regulate hazardous air pollutants from electric utilities. "We do not believe the rule will adequately protect public health and the environment, a concern that is shared by many others," they said.

- STAPPA and ALAPCO strongly urge the agency to abandon its proposed strategy and, instead, develop final Maximum Achievable Control Technology (MACT) standards, with stringent emission limits and expeditious deadlines, as required by Section 112(d) of the Clean Air Act.

- The Clean Air Act clearly calls for emissions of hazardous air pollution from electric utilities to be regulated under Section 112. Therefore, EPA's proposal to regulate those sources under Section 111, instead, is totally inappropriate.

- The limits contained in the Section 111 proposal are not nearly stringent enough. The proposal calls for an interim emissions cap, expected to be 34 tons per year to be achieved by 2010 that, in fact, does not require any additional control of mercury beyond the co-benefits expected from other programs aimed at reducing emissions of sulfur dioxide and nitrogen oxide, such as the Interstate Air Quality Rule (IAQR).

- The EPA proposal sets MACT levels that would result in national emissions of 34 tons per year, which is clearly not consistent with the legislative mandate for calculating MACT under Section 112.

- EPA should establish a MACT standard that reflects *at least* "the average emission limitation achieved by the best performing 12 percent of the existing sources" or "the emission control that is achieved in practice by the best controlled similar source." Rather than recommending a specific

[36] http://www.4cleanair.org/Multi-P%20Analysis-FINAL-031504-lthd.pdf

technology, STAPPA and ALAPCO suggest a performance standard. Also, we prefer a common standard for bituminous and subbituminous coal, but different percent limits can be considered for the coal types, as long as the limits provide for very good controls of mercury emissions and do not promote fuel switching or blending to avoid controls.

- STAPPA and ALAPCO are extremely concerned that EPA is proposing on a national basis to allow trading of mercury emissions between utilities. "Not only do we question the legality of mercury trading, we are also very concerned that trading could lead to serious hotspot problems around the country."

- The concern about local sources causing local mercury hotspots must not be dismissed. Mercury emissions can travel great distances, some of the pollutant can also be deposited near its source. In fact, there is recent evidence that sources of mercury can have significant local impacts.

- STAPPA and ALAPCO believe it is reasonable to consider 90-percent control for sources using bituminous coal and 80-percent control for units firing subbituminous coal. These limits would result in a national emission reduction between 85-90 percent, which is much more stringent than the decreases expected from EPA's proposal.

- STAPPA and ALAPCO strongly urge EPA to abandon its proposed strategy, and, instead, develop final MACT standards with stringent limits as required by Section 112(d) of the Clean Air Act.

THE NORTH CAROLINA DIVISION OF AIR QUALITY

On June 29, 2004, the North Carolina Division of Air Quality (DAQ) addressed problems found with the EPA's proposed and supplemental proposed rules addressing national emission standards for hazardous air pollutants (NESHAP) for mercury and nickel, which were published in the Federal Register January 30, 2004 and March 16, 2004. A copy of the letter is in Appendix B of this report. DAQ's primary concerns extracted from the letter include:

1. The health effects of mercury in North Carolina

   - Mercury is a significant health problem in North Carolina. Methylmercury levels in fish from eastern North Carolina continue to be elevated above all of the existing toxicological benchmarks provided by the federal government.

   - The Department of Health and Human Services has advised women of childbearing age and small children not to consume these three species of fish when caught from surface waters south

and east of Interstate-85, and reduced consumption rates are recommended for the general public.

- Total mercury concentrations in rainwater are at or above levels that water quality agencies would seek in order to restore the ability to eat locally caught fish without an increased risk of neurological effects.

- Significant reduction in mercury emissions to the atmosphere is necessary for public health protection.

2. Comparison of the EPA Proposal with Existing Measures in North Carolina

   - In 2002, North Carolina passed the Clean Smokestacks Act (CSA), which substantially cuts the state's coal-fired power plants emissions of multiple air pollutants that cause smog, haze and other pollution problems. The speed and amount of reduction of EPA's proposal are less than those for North Carolina's own requirements.

   - The pollution controls required under the CSA are projected, as a co-benefit, to reduce mercury emissions in North Carolina by more than 50 percent by 2012.

   - Under the proposed MACT, the reductions projected are 29 percent until 2018 nationally. In addition, there is no guarantee of site-specific reductions due to EPA's proposed Cap-and-Trade system.

1. Relationship Between the EPA Proposal and the Future Steps Required to be taken by North Carolina.

   - DAQ encourages EPA to consider in its final rule the process North Carolina already has in motion for evaluating the health needs and available technologies for achieving additional mercury reductions.

   - Given the significant early reductions from implementation of the CSA, North Carolina hopes EPA will pass regulations that require similar reductions in other States.

   - The EPA rule needs to offer explicit right and authority for States to deal with residual local issues and to avoid preempting State programs.

- Compliance should be monitored using EPA Method 101A, since mercury continuous emission measurements (CEM)s will most likely not be commercially available, accurate, or reliable by the time that a mercury MACT rule is to be implemented. Title V permits will include compliance assurance monitoring (CAM) plans for periods between compliance tests. There should be an initial compliance demonstration followed by annual testing for large sources and biennial testing for small sources to demonstrate compliance with mercury MACT limits.

- Compliance with MACT limits should be on a facility basis rather than on a boiler-by boiler basis.

- The presumptive three-year compliance period contained in § 112(d) is too short to bring all coal-based units into compliance with mercury MACT limits. Several practical concerns limit the ability to design, build and finance the pollution control equipment that would need to be installed or retrofitted for the entire electric utility industry to comply with a MACT standard in only three years.

CHAPTER IV COAL-FIRED BOILER MERCURY CONTROLS

This chapter discusses mercury controls available to the electric utility coal-fired boiler industry. Information presented at the workshop on Mercury and CO_2 during April 19-21, 2004 is italicized.

INSIGHTS ON ECONOMIC IMPACTS OF UTILITY MERCURY AND CO_2 CONTROLS[37]

Various retrofit controls are possible
"Co-benefits" from PM, SO_2 and NO_x control equipment, especially for bituminous (eastern) coals:

- *Cold-side electrostatic precipitator* (CESP) *–removes ~35% of mercury; FF removes 75-90% of mercury*
- *Wet FGD + CESP removes 60-70% of mercury*
- *SCR with WFGD + CESP removes 85-90% of mercury*

Activated carbon injection (ACI):

- *Cheap to install, expensive to operate, for removals of 60-80%*

ACI with small baghouse:

- *Substantial capital cost, but lower operating costs 85%-90% removal appears possible*

All mercury controls still have uncertain removal potentials
Co-benefits are likely, but magnitude still speculative
ACI still being developed; not "commercialized" yet

PERFORMANCE AND COSTS OF MERCURY CONTROL TECHNOLOGY FOR BITUMINOUS COALS[38]

Status of Technologies for Oxidizing Mercury:

SCRs: DOCUMENTING PERFORMANCE ON FULL-SCALE INSTALLATIONS

- *Better performance on bituminous than subbituminous coals.*

---

[37] Insights on Economic Impacts of Utility Mercury and CO2 Controls, Anne Smith Charles River Associates, North Carolina DENR/DAQ Workshop on Mercury and CO2, Raleigh, NC, April 19-21, 2004

[38] Performance and Costs of Mercury Control Technology for Bituminous Coals:, Michael D. Durham, Ph.D.,MBA , ADA-ES, Inc., NC DAQ Mercury and CO2 Workshop April 19-21, 2004 Raleigh, NC

- *Possibility of aging effects.*
- *Possibility of interferences from other chemicals.*
- *Catalysts are being designed to reduce oxidation of SO_3; this may impact oxidation of mercury.*
- *Oxidizing Catalysts: Pilot-scale testing under way.*
- *Oxidizing Chemicals: Some very short-term full-scale tests. Concerns with corrosion.*

SORBENT INJECTION UPSTREAM OF A WET SCRUBBER

- *Injection of AC and capture in ESP will provide an additional mechanism to reduce mercury emissions.*
- *Oxidation of mercury produced by carbon could enhance capture in FGD.*
- *Decreased mercury levels in scrubber could reduce potential for reemission of elemental mercury from scrubber.*
- *Two DOE/Industry full-scale field tests are scheduled:*
    1. *Georgia Power Yates; currently on-going, medium-sulfur bituminous coal, and*
    2. *AEP Conesville; Spring 2005, high-sulfur bituminous.*

ASH ISSUES

- *The mercury captured by PAC, LOI, and ash appears to be very stable and unlikely to reenter the environment.*
- *The presence of PAC will most likely prevent the sale of ash for use in concrete.*
- *Several developing technologies to address the problem:*
    1. *Separation*
    2. *Combustion*
    3. *Chemical treatment*
    4. *Non-carbon sorbents*

5. Configuration solutions such as EPRI TOXECON™

Costs of mercury control depend on plant size not on amount removed.

Costs of mercury control are unrelated to the amount of mercury captured.

CONCLUSIONS ON ACI PERFORMANCE

- *AC injection can effectively capture elemental and oxidized mercury from bituminous coals.*
- *There will be difference in site to site performance of ACI due to differences in coal, equipment, and flue gas characteristics.*
- *Fabric filters provide better contact between the sorbent and mercury than ESPs, resulting in higher removal levels at lower sorbent costs.*
- *Long-term results are promising showing consistent mercury removal greater than 85%.*
- *New COHPAC™ fabric filters will have to be designed to handle higher loadings of PAC to insure high (>90%) mercury removal.*

Commercial Status of Technology: Equipment

- *Similar equipment has been used successfully in the waste industry to inject AC into flue gas.*
- *It has successfully been scaled up for full-scale utility applications.*
- *Operating continuously for nearly a year at Gaston.*
- *Three AC injections systems currently operating.*

Supply of Activated Carbon and Other Sorbents:

- *Sufficient supply available to meet several State regulations.*
- *Additional production needed to meet Federal regulations.*
- *Tremendous progress being made with improved sorbents.*

Performance:

- *Will vary with type of equipment (FF vs. ESP).*

- *Will vary from site to site due to flue gas characteristics (temperature, acid gases).*

WET SO_2 SCRUBBERS

Wet scrubbers are similar to dry scrubbers in that both use an alkaline solution to collect SO_2 and both are located downstream of a particulate air pollution control. However, wet scrubbers saturate the flue gas stream with water, as the complete scrubbing process, including by-products, remains liquid or in a slurry form. They are also referred to as wet FGD scrubbers and normally achieve a SO_2 control efficiency of 90+ percent. In this study it was estimated that wet scrubbers downstream of cold-side ESPs would remove almost 80 percent of total mercury emissions and wet scrubbers downstream of hot-side ESPs would remove nearly 40 percent of total mercury emissions. This decrease in mercury control performance in hot-side ESP is due to the relatively lower amount of mercury oxidized at elevated temperatures. Relative to other air pollution controls, wet scrubbers downstream of cold-ESPs show higher mercury removal performance because the gas temperature favors more oxidized mercury, with the oxidized fraction being more effectively removed in the scrubber. The challenge to improve performance of mercury capture in wet FGD is to find a way to oxidize the elemental mercury vapor before it reaches the scrubber or to modify the liquid phase of the scrubber to cause oxidation to occur. Wet FGD scrubbers are installed on about 15 percent of utility boilers nationwide, most of which are on the larger boilers, as these scrubbers control roughly 25 percent of the US power generating capacity. No wet FGDs are currently installed on any NC boilers, but 22 boilers will have their emissions scrubbed by wet FGDs as a result of the CSA.

SELECTIVE CATALYTIC REDUCTION

The SCR process uses a catalyst with ammonia gas to reduce the nitric oxide (NO) and NO_2 in the flue gas to molecular nitrogen and water. Ammonia gas is diluted with air or steam, and this mixture is injected into the flue gas stream upstream of a metallic catalyst bed composed of vanadium, titanium, platinum, or zeolite. In the reactor, the reduction reactions occur at the catalytic surface. The SCR catalyst bed reactor is usually located between the economizer outlet and the air heater inlet, where temperatures range from 450 – 750 °F. Recent data suggests that SCRs tend to promote additional mercury oxidation, thereby enhancing mercury removal with most existing and emerging particulate / SO_2 control technologies. Eleven SCRs are being installed in North Carolina as a result of the NO_x SIP Call and the CSA.

COLD-SIDE ESP RETROFIT OPTIONS

ADD FLUE GAS COOLING

Lowering the flue gas temperature entering the ESP assists natural fly ash sorption of mercury, improves the performance of any sorbents injected upstream for mercury control, and inherently enhances particulate control performance by reducing gas velocity and lengthening residence time. However, the acid dew point temperature limits the

extent of gas cooling when the flue gas has significant formation potential of hydrochloric acid or sulfuric acid that greatly reduces the service life of steel ducts.

POWDERED ACTIVATED CARBON BASED CONTROL[39]

Conventional Powdered Activated Carbon (PAC)

- *Control requires a fabric filter to achieve acceptable mercury removal efficiency.*
- *Bromated powdered activated carbon (bpac) is much more reactive and has to potential to provide acceptable mercury control with an ESP*

Gaseous mercury can be converted to particle–bound mercury by adsorption onto solid particles in the flue gas. Injecting suitable sorbents into the flue gas upstream of the ESP increases the amount of mercury captured. This modification may also require additional ducting between the injection location and the ESP inlet, and adding a gas absorber / humidifier upstream of the ESP. This approach may be limited to ESPs with a wide compliance margin, as boilers with marginally performing ESPs may have difficulty meeting existing particulate-related emission requirements due to the increased loading of sorbent and likely high resistivity levels.

ADD DOWNSTREAM FABRIC FILTER WITH SORBENT INJECTION

Installing a fabric filter after the ESP allows most of the native collected fly ash in the ESP without reacted sorbent and enhances overall particulate control for marginally performing ESPs. Furthermore, due to the low particulate loading, the filter dust cake porosity is reduced, allowing use of a smaller, less expensive fabric filter with long cleaning cycles and high sorbent and bag life performance.

COHPAC OPTION™

There is a patented variation of adding a downstream fabric filter (baghouse) to a cold- or hot-side ESP known as COHPAC™ (Compact Hybrid Particulate Collector) developed by the Electric Power Research Institute. It involves retrofitting a baghouse either in the space of the last field (or section) of an ESP or in a separate housing downstream of an ESP with a precharger located immediately upstream of the baghouse. In either case, the residual or induced charge on the particulate produces a marked effect in lowering the porosity of the filter dust cake. Such an arrangement allows use of a much smaller, less expensive fabric filter with long cleaning cycles and high sorbent and bag life performance. For example, COHPAC™ units are designed with filtration velocities of 8-12 feet per minute (fpm) as compared to the filtration velocities of 3-5 fpm typically used for pulse-jet fabric filters on coal-fired utility boilers.

---

[39] Mercury Monitoring, Barrett Parker, EPA Emissions Measurement Center, Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

HOT-SIDE ESP RETROFIT OPTION.

This entails conversion of a hot-side ESP to a cold-side ESP, and could then include any of the other cold-side ESP retrofit options mentioned above. Several hot-side ESPs in the US, including a few in NC (such as Duke Energy Allen Units 3-5), have been converted to cold-sides to improve particulate collection performance and ESP reliability. Depending on plant layout and design, this may be possible by reconfiguring the ducting, retuning the ESP to operate at lower temperatures, and perhaps installing a SO_3 or NH_3 gas conditioning system to restore performance.

WET FGD SCRUBBER RETROFIT OPTIONS

Previous research has shown that much of the mercury released during coal combustion is either removed with the flyash or can be absorbed in FGD units, if it is in the oxidized form. Oxidation of the gaseous elemental mercury is more readily captured by wet FGDs than gaseous elemental mercury. Several flue gas additives and scrubbing liquid additives are being developed to oxidize more of the gaseous elemental mercury and to prevent any re-conversion of oxidized mercury to gaseous elemental mercury. However, there is the caution that increasing oxidants in the flue gas or in the scrubbing liquid may also oxidize other species such as SO_2 and NO_x to sulfuric acid and nitric acid aerosols. Other options under development include use of oxidizing catalysts upstream of scrubbers, higher scrubber liquid-to-gas ratios, and scrubber tower design changes.

DRY SORBENT INJECTION.

For boilers with dry air pollution controls without FGD, injection of dry sorbents (such as powdered activated carbon [PAC] or less costly alternatives) offer a candidate control technology. Because of the added contact on the filter dust cake, it is estimated that FFs would require 1/10 of the sorbent rate as ESPs. Full scale tests with a small FF downstream of a hot-side ESP showed 90 percent mercury control with PAC injection. Such performance was achieved with a significant increase in bag cleaning frequency (a reliable surrogate indicator for a decrease in bag life and increase in bag replacement cost) with the suggestion of rather high overall cost for the PAC injection system. Further full scale tests have been performed at a Wisconsin electric utility. [Reference: "Full Scale Evaluation of Mercury Control with Sorbent Injection and COHPAC..."] Other tests have/ are being performed with Darco FGD™ carbon injection upstream of ESPs. Results with low sulfur bituminous coal show total mercury capture vary from 20 – 80 percent depending on ESP operating temperature ranging from 220 – 275 °F.

Sorbent collection performance for mercury is expected to depend on 5 key parameters, including sorbent size, sorbent capacity, residence time, type of dry air pollution control, and mercury level. Predicted costs for PAC using representative values for these parameters range from $4-12 million/year for ESPs and from $4-6 million/year for FFs for a 500 MW boiler. (Since these levels are considered prohibitive by some, many other candidate technologies target cost levels as ¼ to ½ of PAC costs.). Title: "Predicted Cost of Mercury Control at Electric Utilities Using Sorbent Injection"

CALCIUM-BASED SORBENT INJECTION

An alternative to PAC is calcium-based sorbent, such as limestone. EPA laboratory tests indicated that injection of calcium-based sorbents into flue gas could result in significant mercury removal and a small amount of SO_2 and SO_3 removal. Further testing by McDermott Technology, Inc. produced results slightly above 50 percent mercury capture. Comparison of these results with PAC results indicate that while PAC is a more effective sorbent than limestone on a mass basis, limestone is a more effective sorbent than PAC on a cost basis.

In summary, there are several emerging potential retrofit mercury control technologies at various stages of investigation and development. Further efforts to study and validate full-scale performance are underway, but it appears premature to obtain a complete set of definitive cost data for performing a robust cost analysis for many/most of the competing mercury control technologies.

IGCC: WHAT IS IT?[40]

INTEGRATED COAL GASIFICATION COMBINED CYCLE (IGCC)

- *Chemical conversion of coal to synthetic gas for combustion in a modified gas turbine.*
- *Inherently cleaner process because coal is not combusted and the relatively small volumes of syngas are easier to clean up than the much larger volumes of flue gases at a coal combustion plant.*

IGCC ENVIRONMENTAL IMPACTS - AIR POLLUTION

- *Commercially available IGCC power plant technologies can have much lower air pollution emissions than new conventional coal plants.*
- *Actual air emissions performance will likely depend, at least in part, on what control technology and performance levels are required by regulators.*

Mercury capture at IGCC plants is quite feasible and much less costly than at conventional coal plants and the potential exists to indefinitely sequester mercury captured at IGCC facilities.

Commercially available IGCC power plant technologies produce substantially smaller volumes (about one half) of solid wastes than do new conventional coal plants using the same coal

---

[40] Integrated Coal Gasification Combined Cycle (IGCC) Power Plants and Geologic Carbon Sequestration, Joe Chaisson, April 21, 2004, Revised. Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

IGCC solid wastes are less likely to cause environmental damage than fly ash from conventional coal plants because IGCC ash melts in the gasification process, resulting in an ash much less subject to leaching pollutants than is conventional coal combustion fly ash.

COAL GASIFICATION AND MERCURY MANAGEMENT

- *Proven, low cost mercury controls can remove most of the mercury from coal syngas produced (14 years experience at Eastman Chemical).*

- *Mercury is captured in a small volume activated carbon bed. Bed contents are currently managed as hazardous wastes (due to other toxics captured), but could be sequestered in a long-term mercury storage facility or the mercury contained could be economically recycled.*

Thus coal IGCC with a carbon bed plant mercury control is today the only technology that can convert coal to power and capture nearly much of the coal mercury in a form and volume suitable for permanent sequestration.

CHAPTER V TWO MERCURY EMISSION ESTIMATING TOOLS

In 1999, the U.S. Environmental Protection Agency (EPA) conducted the Electric Utility Steam Generating Unit Mercury Information Collection Effort (EU/ICE) to gather information about mercury emissions from the coal-fired electric utility industry. This effort led to the collection of stack test and coal mercury content reports on 80 furnace or boiler units. Two computer tools have been used in this report to estimate mercury emissions leaving the smokestacks of coal-fired electrical utility boilers. Both tools are based on the same data. For this report, the two tools are differentiated as the EPA tool and the EPRI tool.

The EPA tool, "Electric Power", "*EUCFF*" (Version 3.0.1) was developed for EPA by the Research Triangle Institute in June 2001 for estimating mercury emissions from coal combustion at electrical utilities in the United States. *Electric Power* allows permitting authorities and others to evaluate the impact on mercury emissions if certain parameters including type of coal, boiler, or pollution control device are changed.[41] This program does not account for any additional mercury capture if selective catalytic reduction (SCR) equipment is installed in the flue gas stream. Therefore, if an SCR is installed, the actual mercury emissions may be lower (more captured) than emissions otherwise reported. The EPA tool results are more conservative that the EPRI tool results because the EPRI tool program algorithms incorporates the affects of high chlorine in coal combusted in North Carolina. Chlorine combines with mercury to form inorganic molecules that can be captured.

The EPRI tool was used to develop EPRI's technical Report "An Assessment of Mercury Emissions from U.S. Coal-Fired Power Plants," in October 2000. Due in part to the reason cited above, the EPRI tool normally estimated higher mercury capture rates than the EPA tool. However, in light of data variability and other uncertainties that may exist during the massive data collection and testing effort, DAQ believes it prudent to report estimated mercury capture with a range of values instead of exact numbers.

Information presented at the workshop on Mercury and CO_2 during April 19-21, 2004 is italicized.

A SOFTWARE TOOL FOR ESTIMATING MERCURY EMISSIONS AND REDUCTIONS FROM COAL-FIRED ELECTRIC UTILITIES (EU)[42]

- *Tool for evaluating alternatives for mercury control.*
- *Case-by-case MACT is applicable until nationally applicable MACT standard*

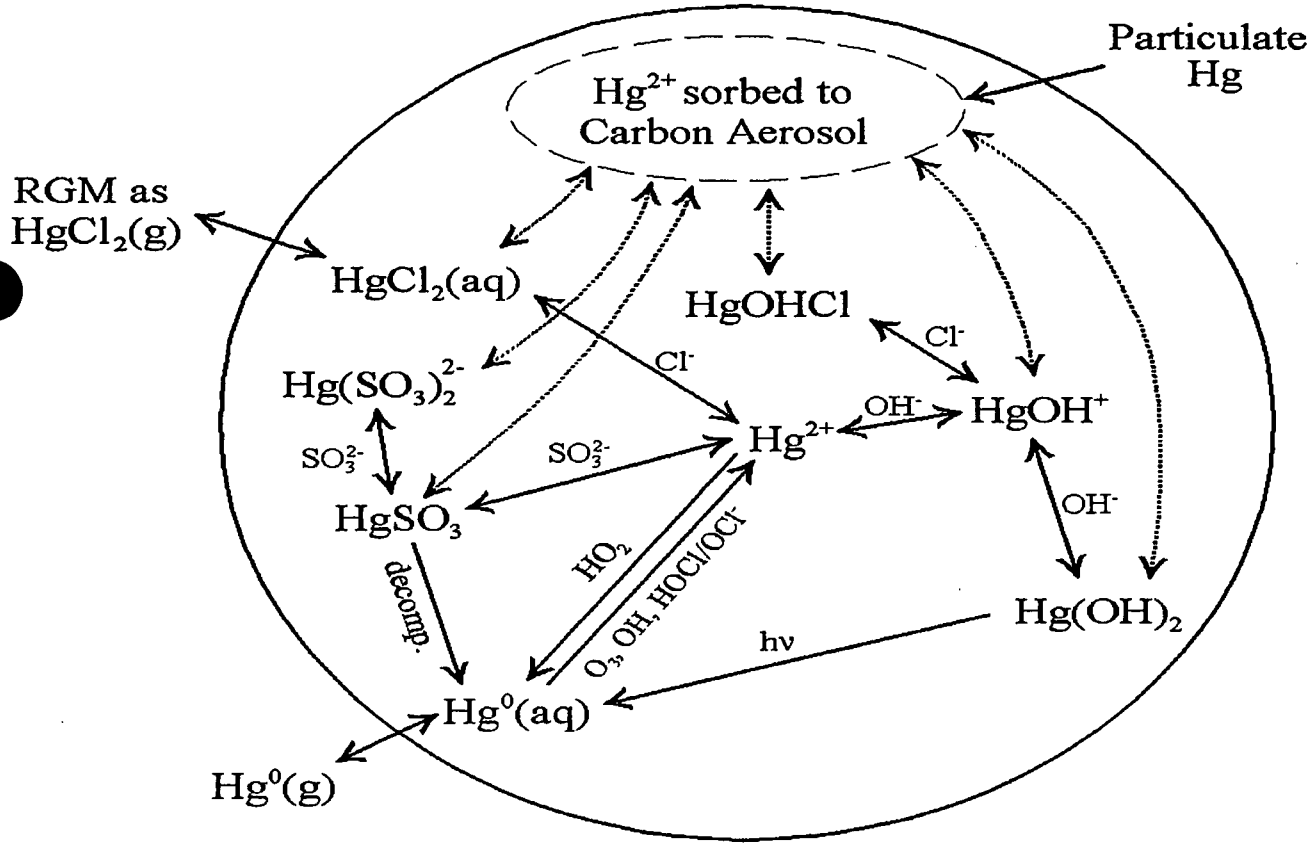
CHAPTER VI LOCAL MERCURY SOURCES AND INFLUENCES

Information presented at the workshop on Mercury and CO_2 during April 19-21, 2004 is italicized.

MODELING ATMOSPHERIC MERCURY DEPOSITION[44]

It is well known that particulate matter deposits from the atmosphere through dry processes, but gaseous constituents also dry deposit. It appears that dry deposition of RGM is especially important near combustion sources. Figure VI-1 graphically illustrates the complex chemical reactions taking place in the atmosphere resulting in dry mercury deposition.

FIGURE VI-1
CLOUD CHEMISTRY MECHANISM FOR THE CMAQ-MERCURY MODEL



[44] Modeling Atmospheric Mercury Deposition to the Sounds and Other Water BodiesO. Russell Bullock, Jr., NOAA Air Resources Laboratory,(On assignment to the U.S. EPA Office of Research and Development), Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

- *The Florida everglades experience provides the best example so far of the likely importance of dry deposition of mercury to total ecosystem impacts.*

- *Atmospheric mercury models are under development at a number of institutions around the world, and a concerted effort of model inter-comparison is being made to identify important uncertainties.*

- *Sparse and incomplete observational data is hampering model evaluation efforts, especially the lack of closure on the total deposition flux.*

- *Atmospheric mercury models will continue to evolve as our understanding of mercury chemistry in air and cloud water evolves.*

The greatest obstacle to discovery is not ignorance - it is the illusion of knowledge.

Daniel J. Boorstin (1914-2004)

ATMOSPHERIC MERCURY: PANDORA'S BOX?[45]

Comparison of mercury inputs to the Everglades, depicted is the Everglades Protection Area, i.e. the remaining 'natural' portions of the Everglades:

- *Two years' monitoring of surface water inflows of mercury from all of the 'into' structures were 1.8 and 3.2 kg/year, during which atmospheric deposition from 4 years of rainfall mercury collection ranged from 125 to 140 kg/year.*

- *Thus, greater than 95% of the annual mercury budget of the Everglades comes from atmospheric deposition via rainfall.*

- *Atmospheric modeling of sources within southern Fla. indicates that dry deposition adds approximately 30% additional mercury load to WCA-3A, not included in these estimates.*

The Bottom Line

- *Reduction of atmospheric sources of mercury from within Florida has led to ~ 60% declines in mercury in Everglades fish and wildlife in less than 15 years since peak deposition.*

- *To the extent that mercury emissions are in the reactive form (RGM) one can expect to see benefits at local or regional scale within years to decades.*

---

[45] Atmospheric Mercury: Pandora's Box?, Tom Atkeson, Coordinator Mercury & Applied Science, Workshop on Mercury and CO_2, Raleigh, NC, April 19-21, 2004

- *The main driver of the Everglades mercury problem is mercury load - overwhelmingly from atmospheric deposition.*

- *There is synergy with co-deposition of mercury and sulfate, which combine to exacerbate mercury methylation.*

Figure VI-2 reflects annual mercury deposition rates from approximately 1810 to 1996 that was analyzed from a sedimentary core sample collected in the Everglades. Mercury dropped back to 1980 deposition rates from a high in the early 1990s.

Figure VI-3 shows the reduction of mercury use throughout the world's economy. This decline has been of the order of 80 percent.

THE FLORIDA EVERGLADES STUDY RESULTS[46]

The Florida Everglades study goal was to understand and simulate how changes in local atmospheric mercury emissions in south Florida would influence mercury concentrations in top predator fish, thus demonstrating the potential of combining air and water modeling approaches in Total Maximum Daily Load (TMDL) involving air deposition of mercury. This study focuses on mercury, and incorporates extensive field data into a framework combining atmospheric mercury deposition and aquatic mercury cycling models to demonstrate the feasibility of the approach. The data year studied for this project is from June 22, 1995 to June 21, 1996.

A fundamental question to examine in this pilot TMDL study was the relationship between atmospheric reactive gaseous mercury (RGM) deposition and long term fish mercury concentrations. Once the model was calibrated to the current atmospheric RGM deposition estimate of 35 μg/m2/yr, simulations were also carried out with loadings at 75, 50, 25 and 15percent of current levels. In these simulations, RGM and methylmercury concentrations in inflows were adjusted in proportion to RGM deposition. Atmospheric loadings of methylmercury also were changed proportionally. Predicted fish mercury concentrations were compared after each simulation had run 200 years, producing essentially steady state conditions. Annual cycles of site conditions and mercury deposition were repeated Inorganic mercury throughout the simulation period.

The purpose of including the results of this Florida Department of Environmental Protection study is an attempt to establish a link between airborne mercury emissions and methyl mercury concentrations in top predator fish. The findings point to a linear relationship existing between airborne mercury emissions and methyl mercury concentrations in three-year-old big mouth bass. See Figure VI-4.

A fundamental question to examine in this pilot TMDL study was the relationship between atmospheric inorganic mercury deposition and long term fish mercury concentrations. Once the model was calibrated to the current atmospheric inorganic mercury deposition estimate of 35 μg/m2/yr., simulations were also carried out with loadings at 75, 50, 25 and 15 percent of current levels. In these simulations, Inorganic mercury and methylmercury concentrations in inflows were adjusted in proportion to Inorganic mercury deposition. [46] Integrating Atmospheric Mercury Deposition with Aquatic Cycling in South Florida: An approach for conducting a Total Maximum Daily Load analysis for an atmospherically derived pollutant, Florida Department of Environmental Protection, October, 2002, Revised November, 2003

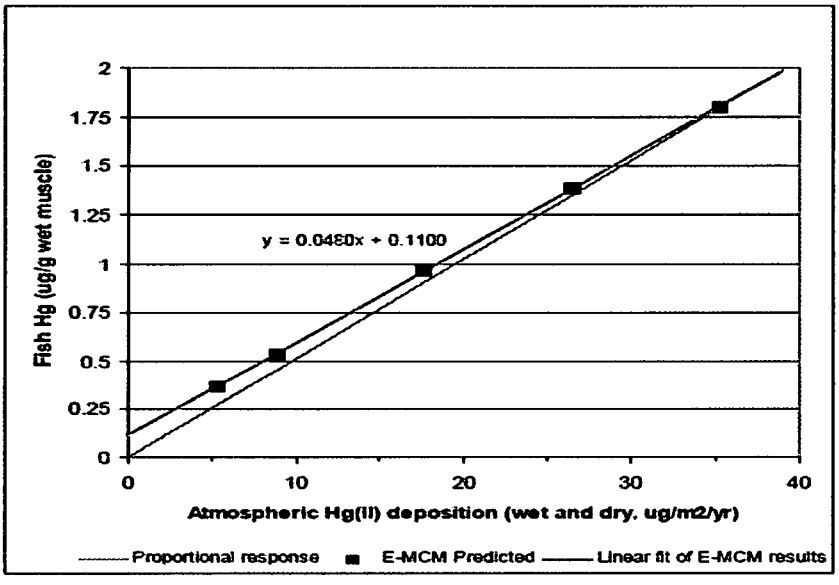
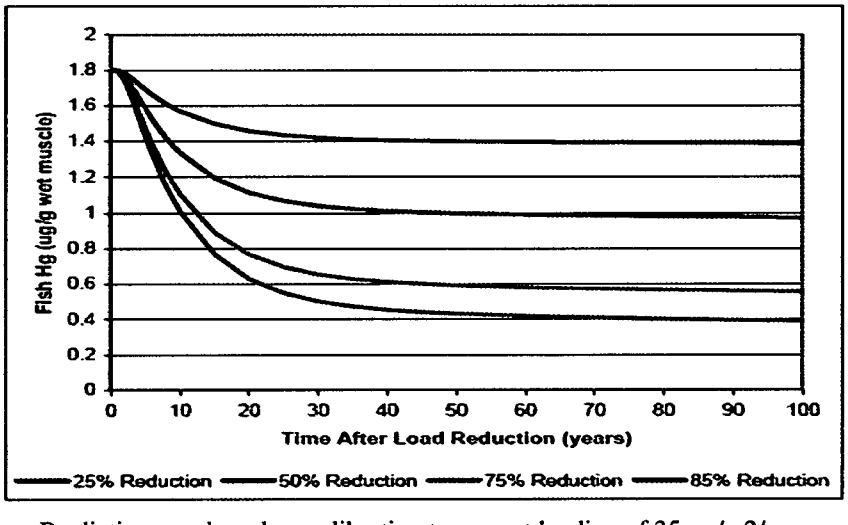
FIGURE VI-4
THREE YEAR OLD LARGEMOUTH BASS PREDICTED MERCURY CONCENTRATIONS (AS A FUNCTION OF DIFFERENT ATMOSPHERIC MERCURY DEPOSITION ANNUAL RATES)



Atmospheric Inorganic mercury deposition (wet and dry, ug/m2/yr)
Fish mercury (ug/g wet muscle)

It is unknown at this time if the results of this study are applicable in North Carolina as a predictive tool. South Florida's metrological experience is very different from that found in this State. There are also major differences in mercury sources, topography, soil structure, and exposure to pollution affects across state borders.

FIGURE VI-5
PREDICTED DYNAMIC RESPONSE OF MERCURY CONCENTRATIONS IN LARGEMOUTH BASS IN WCA 3A-15 FOLLOWING DIFFERENT REDUCTIONS IN RGM DEPOSITION.

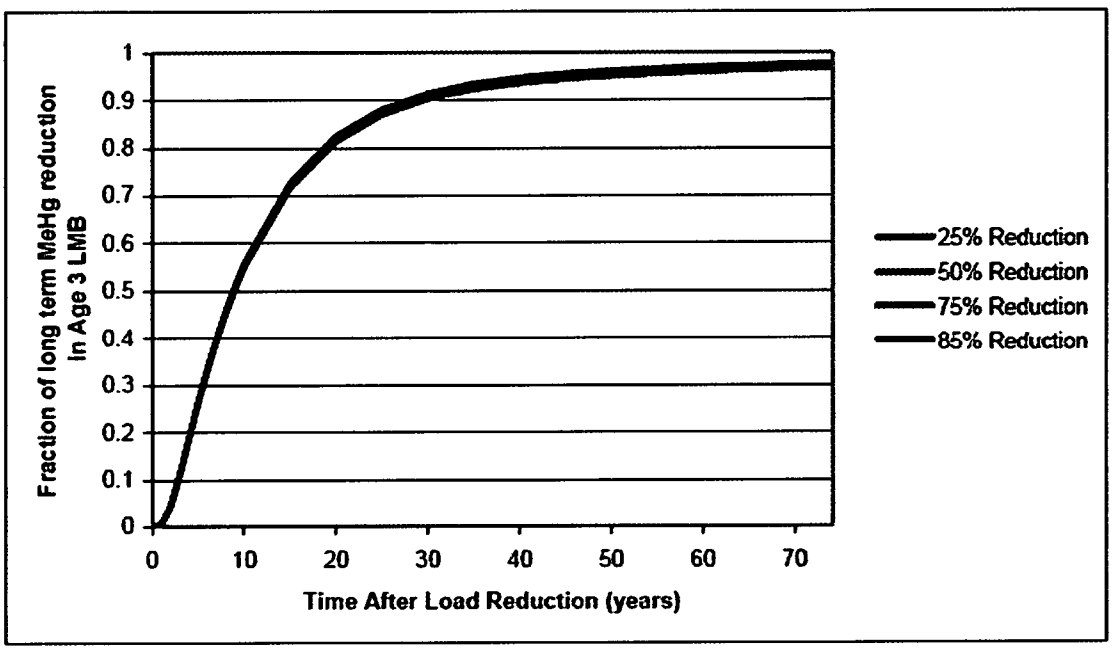


Predictions are based on calibration to current loading of 35 µg/m2/yr.

Figure VI-6 shows that the number of years required for the system to approach a new steady state is effectively independent of the actual magnitude of the change. Two phases are illustrated by the curve: the first is a period of comparatively rapid response driven by the decline of inorganic mercury loading and the hydraulic residence time of the system; the second phase is far slower, and is governed by the turnover rate of labile inorganic mercury in the sediments supporting methylation. Because the simulated concentrations of mercury in largemouth bass ultimately reflect net methylation rates in the sediments, the response of largemouth bass is prolonged. For example, the time required to achieve 50 percent of the ultimate response in fish tissue mercury concentrations is approximately 10 years for all load reduction scenarios tested with the base calibration with atmospheric inorganic mercury deposition at 35 μg/m2/yr. Within 30 years, approximately 90 percent of the ultimate predicted response is projected to occur.

Figure VI-6

Comparison Of The Rate At Which Age 3 Largemouth Bass Concentrations Approach Steady State Following Different Reductions In Inorganic Mercury Deposition



Simulations all based on calibration with current Inorganic mercury deposition = 35 μg/m2/yr.).

The report discusses uncertainties in some detail. Causes of uncertainty are listed to encourage the reader to understand that this report, excellent as it is, may or may not represent the true relationship of atmospheric mercury deposition to methylmercury contamination in fish:

- No simple relationship links mercury concentrations in water and mercury concentrations in fish; the relationship is site specific.

- The average annual precipitation for the study year was 156 cm. The normal precipitation range at the site is 125-140 cm.

- The model indicates a significant seasonal trend in total mercury wet deposition to the area, predicting that over 80 percent of the wet deposition would occur from May through October.

- The program used measured wet deposition (23.1 $\mu g/m^2$/year) and modeled estimate of dry deposition (12.2 $\mu g/m^2$/year). For a total of 35 $\mu g/m^2$/year.

- Assumption that two limiting factors govern methylation and demethylation rates: the supply of available mercury and the rate of activity of the methylating and demethylating microbes.

- Assumption that microbial methylation and demethylation rates were limited only by their respective mercury substrates.

- Assumption that RGM and methylmercury concentrations in inflows would respond linearly to changes in atmospheric deposition.

- Several attempts have been made at construction of global mercury models but all lack key information on the atmospheric reactions of mercury and their rates.

- The understanding of the biogeochemical cycle of mercury has advanced greatly in the past decade but a number of features of that cycle remain obscure. The program was calibrated to a single site in this study.

- Unable to compare model predictions to observations in terms of the effects of different site conditions such as pH, DOC, fish growth rates, sulfate and sulfide levels, and other site conditions that vary systematically across the Everglades.

THE FLORIDA MERCURY REPORT – PUTTING IT IN PERSPECTIVE[47]

EPRI Comments on "Integrating Atmospheric Mercury Deposition With Aquatic Cycling in South Florida"

Recent news coverage of the Florida Mercury Report published on November 6 indicates that the installation of mercury emission control technology on waste incinerators in the early1990s has resulted in a 60-70% decrease in mercury concentrations in fish and birds in the Everglades. Does this mean that placing mercury emission controls on power plants throughout the United States would have a similar effect?

The mercury emissions released by municipal and medical waste incinerators are

[47] *The Florida Mercury Report – Putting it in Perspective,* EPRI • askepri@epri.com • www.epri.com

different from those released by power plants.

- There are two major forms of mercury in emissions – oxidized (or ionic), which is water-soluble, and elemental, which is not water-soluble.

- Most incinerator mercury is in the water-soluble form whereas the form of mercury released from power plants depends upon many factors, such as the type of coal being burned. Recent research has shown that most of the mercury released by utilities (at least 60 percent) is the non-water soluble elemental form, and that a significant amount of the remainder converts to this non-soluble form shortly after leaving the stack.

- The form of mercury emitted is critical as oxidized mercury can be washed into local rivers, lakes, and streams by rainfall whereas elemental mercury is carried away by wind and enters the global mercury cycle.

- Power plant chimneys are typically higher than incinerator chimneys and therefore disperse emissions over a larger area, resulting in less local impact.

The Florida Everglades represents a unique ecological system not typical of, and in fact, strikingly different from other US waterways. Thus, the results from this study are not necessarily applicable to other areas.

- The Everglades are in a tropical zone (no seasons), the water is shallow, and the bottom sediments are much different from those in other water bodies throughout the U.S. Other waterways also have different levels of acidity, biological activity, dissolved oxygen, and turbidity. These differences can dramatically affect mercury cycling and uptake by biological organisms. Thus, it is unlikely that the changes in mercury, both amount and rate of decline, observed in fish would be observed in other US waters.

The claim that changes in mercury emissions result in rapid changes in fish mercury content is not supported by the data or findings.

- The Florida report assumes that mercury deposition in the Everglades originates from local sources (primarily incinerators and power plants). However, while such patterns might be expected, data measurements and long-range transport modeling indicate otherwise.

- In fact, despite decreases in mercury emissions from incinerators, the amount of mercury being deposited in the Everglades overall has not changed significantly.

- Indeed, both EPA and EPRI have modeled mercury transport and concluded that over 60 percent of mercury deposited in Florida originates outside the State.

- Since fish mercury content has apparently fallen, other factors must be involved. Several theories have been suggested involving changing nutrient levels and water flows in the Everglades. Further research is needed to understand this situation.

- An April 2004 researchers' review of the Florida mercury findings concluded that the observed fish mercury trends could not be explained solely by estimated changes in mercury emissions, but needed data on other atmospheric components that might be required to drive such trends.

The atmospheric transport model used by the State of Florida to estimate mercury deposition has limitations.

- The model does not incorporate chemical reactions in the atmosphere. It also does not include global sources of mercury, only local emissions. Thus, it cannot effectively simulate the actual mercury deposition.

EPRI's recent research findings indicate that power plant mercury controls would not significantly change the amount of mercury contained in fish, or the human exposure to it.

- In early 2003, EPRI completed a comprehensive study of US power plant mercury emissions, potential mercury controls, and responses of fish to changes in mercury in their habitat waters. The results showed that reducing mercury emissions from power plants by approximately 50 percent would result in a reduction of mercury in fish of about 1½ percent . This study, combining atmospheric data and models, fish consumption information from US government studies, and an economic model of the US utility industry, relies on more recent information than the two-year-old Florida study report released on November 6.

THE ISSUE OF MERCURY "HOT SPOTS"

MERCURY DEBATE CONCENTRATES ON HOT SPOTS[48]

There's no argument that mercury is a noxious pollutant yet there is widespread disagreement over how or whether to control it. Now the attention is on potential "hot spots," whereby individual power plants could end up not cutting mercury-related emissions under a free market approach espoused by the Bush administration and others. The issue has come to light because of the trading system proposed by the Bush team—the same kind used successfully to help control sulfur dioxide emissions. Simply put, power plants that run afoul of the caps can buy credits from those that exceed their targets. That's the cap-and-trade part of it. The other aspect is that the plan sets a limit of 34 tons of mercury deposits by 2010, or a reduction of 30 percent from today's levels—a number that the Energy Information Administration predicts would be more like 40 percent because of the addition of the trading approach.

---

[48] http://www.rppi.org/mercurydebate.shtml

But, many environmental groups oppose such tactics, noting that while national mercury levels may drop, specific places will suffer from hot spots unless maximum allowable levels are set by individual plants. A cap-and-trade program raises the possibility that any utility could choose to buy credits rather than implement modern pollution controls. Individual communities could therefore suffer harm.

ENVIRONMENTAL DEFENSE REPORT NAMES TOP 10 U.S. MERCURY 'HOT SPOTS'[49]

"Mercury hot spots sound the alarm for strong national limits on dangerous mercury pollution," said Michael Shore, Environmental Defense senior air policy analyst. "EPA's weak stance on mercury ignores the agency's own scientific assessment and puts profits of the utility industry ahead of children's health. Affordable technology exists to protect our children from toxic mercury pollution and it is the government's legal and moral responsibility to put those tools to work now."

According to the report, the top 10 states for mercury hot spots (ranked by the most severe hot spot in each state) are Indiana, Michigan, Maryland, Florida, Illinois, South Carolina, North Carolina, Pennsylvania, Texas and Tennessee.

"America's children can't afford for the EPA to get a failing grade on the cleanup of toxic mercury emissions from coal-fired power plants. Other polluters have already been required to reduce their mercury emissions by 90 percent, and coal-fired power plants should not be let off the hook. States with mercury hot spots should vigorously pursue strong standards to protect water quality, ensure fish are fit to eat, and prevent brain damage in children," said Shore.

Somewhere north of Fort Wayne lies an area of nearly 500 square miles considered to be the most mercury-contaminated spot in the country, according to figures from the U.S. Environmental Protection Agency. Environmental Defense, a private non-profit organization, released the figures compiled earlier by the EPA, but never published, in December, listing the 484-square-mile "hot spot" as leading the country in mercury deposits.

Using data from 1998, the Environmental Defense report is based on a complicated computer model that analyzed weather patterns, mercury emissions from area coal-fired power plants and other information, said Michael Shore, a senior policy analyst for Environmental Defense.

The report from Environmental Defense, a national organization of 400,000 members founded in 1967, does not give a source for the contamination. Nor does it specifically define the hot-spot area by county lines or municipal boundaries. Instead, the report used mapping done by the EPA that divided the country into 22-mile-by-22-mile square grids. The checkerboard square with the most mercury deposits was a grid ambiguously described as being north of Fort Wayne, Shore said. "It's not a precise spot," he said.

---

[49] http://www.fortwayne.com/mld/fortwayne/news/local/7685703.htm Laura Johnston / Ft. Wayne Journal Gazette 11 Jan 2004

"When you look at the specific sites, when you look at the states in the Midwest and the East, there are hot spots all over. The places where mercury deposition is highest, local sources dominate." Shore blamed the coal-fired power plants in Indiana, as well as plants in northeast Illinois and western Ohio, for the contamination.

The Indiana Department of Environmental Management is aware of the mercury issue, which it considers a national problem, spokeswoman Laura Pippenger said. The agency is working with the EPA to find out how it gathered and interpreted the data that indicated the northeast Indiana hot spot. "This sort of modeling can have discrepancies that can indicate a hot spot like this," Pippenger said. But the Environmental Defense study shows that mercury pollution is caused by power plants nearby, Shore said. "It travels to some extent, but communities that live around the power plants are most at risk to mercury pollutants," said Jones, of the Indiana Public Interest Group. Shore and Jones hope that information will convince the Bush administration to enact tough regulations on power plants. "If we're going to clean up pollution, we need to reduce mercury from local sources," Shore said.

"HOT SPOTS"—MERCURY EMISSIONS AND DEPOSITION PATTERNS[50]

There are concerns about potential mercury "hot spots" in the United States, particularly those that might be associated with power plant emissions and might not diminish, but actually become more numerous or severe, following proposed power plant regulations. EPRI has addressed this issue using computer modeling and data analyses, and concludes that mercury emissions from power plants will not create or intensify any hot spots under regulations proposed by EPA. Indeed, power plants contribute little to the areas of highest deposition in the United States, either currently or in future regulated scenarios.

In its December 2003 proposals to regulate mercury emissions from power plants, the EPA defined mercury "hot spots" as locations where deposition contributed by power plants alone is enough to raise mercury in fish tissue above the level EPA deems safe to consume. This is also the highest permissible level for waterways not to be classified as mercury impaired. In general, mercury hot spots are areas of excessively high mercury deposition compared to national or regional averages. Widely scattered measurements of the amount of mercury depositing in rainfall and other precipitation show no strong gradient from the Midwest to the East that might reflect the greater number of mercury sources in the eastern United States. However, simulations done with some computer models have led to speculation that some unmeasured U.S. locations may experience elevated mercury deposition compared with nearby areas, meeting the general definition of hot spots. There are concerns that a cap-and-trade regulatory approach, one of the alternatives proposed by EPA, will allow some electric utility sources to increase the amount of mercury they emit—or will not require them to reduce emissions as much as a Maximum Achievable Control Technology (MACT) approach would. Thus, there has been speculation that the cap-and-trade approach may have the potential to create or exacerbate mercury hot spots.

---

[50] http://www.epri.com/corporate/discover_epri/news/HotTopics/env_HotSpots.pdf. June 2004

EPRI has applied state-of-the-art modeling to evaluate the potential for hot spots under alternative approaches to regulating utility mercury proposed by EPA.
Because it is impractical to look for "hot spots" by measuring mercury deposition at every location in the country, EPRI has run sophisticated, state-of-the-art computer models to simulate deposition of the mercury released from power plants and other emission sources. EPRI's analysis considered the amount and chemical forms of mercury emitted from every coal-fired power plant in the United States under three scenarios: a 2004 Base Case, for current conditions; and EPA's two proposed regulatory approaches, the MACT rule and the Cap & Trade rule. The model simulations of regulatory scenarios are for year 2020, when all emission reduction measures mandated by either rule will be fully implemented. The Base Case simulates mercury emissions from power plants and all other mercury sources, such as municipal and medical waste incinerators. The two regulatory scenarios lower power plant emissions according to requirements of the proposed MACT or Cap & Trade rules, but keep emissions from other sources constant. Holding emissions from other sources constant while varying emissions only from power plants allows researchers to estimate the impacts of EPA's proposed approaches to regulating utility mercury.

To perform the simulations, EPRI used a national economic model to evaluate the amount and chemical forms of mercury emitted from U.S. power plants under each scenario. These emission results were fed into a fine-scale model of mercury chemistry and physics in the atmosphere, which was used to calculate amounts and patterns of deposition throughout the United States under current conditions, the MACT rule, and the Cap & Trade rule.

EPRI's results show that the highest values of modeled deposition in the United States are produced by mercury emitted from sources other than power plants.
According to EPRI's computer simulations, after regulation, the areas of highest mercury deposition in the United States will continue to be those locations chiefly affected by emissions from sources other than power plants. Even with a liberal definition of utility-influenced deposition locations (i.e., where utility-emitted mercury makes up roughly 30 percent or more of the total deposition), only about 2.5 percent of US surface area falls into this category following MACT or Cap and Trade. The leading non-utility mercury deposition locations receive most of their mercury from municipal and medical waste incinerators. Locations affected by these incinerators would continue as the leading areas of mercury deposition in the mid-Atlantic and southern New England states, even after power plants have fully reduced their emissions. This result holds for either the MACT rule or the Cap & Trade rule. While distant non-U.S. mercury sources are the dominant contributors to deposition in much of the United States, non-utility U.S. sources emit mercury at rates and in forms that dominate deposition in their regions. Even after power plant sources are controlled, incinerators will continue to dominate the mercury contributing to deposition in high-deposition areas. Both regulatory approaches proposed by EPA would play an important role in reducing deposition in locations that have substantial deposits from utility sources in 2004. Power plant dominated locations would subsequently fall below the top 55 locations of highest human-caused deposition under either regulatory approach. However, the Cap & Trade approach would produce

markedly lower deposition at utility-dominated locations than would the MACT approach.

Neither proposed regulatory approach would increase deposition in high-deposition areas or create new high-deposition areas compared to current levels. The Cap & Trade rule produces greater mercury deposition reductions than does the MACT rule.

Modeling results for 2020 show that all states in the country will experience overall reductions in deposition due to the proposed mercury rules. But the reduction in mercury deposition is greater under the Cap & Trade rule (an average drop of 7 percent) than under the MACT rule (an average drop of 5 percent). Reductions in deposition vary somewhat by location, with greater reductions occurring in the mid-Atlantic and Southeastern states. This is because the proposed rules incorporate greater incentives for power plants in these regions to pursue mercury controls. Those power plants tend to burn bituminous coal, which emits a relatively higher proportion of divalent mercury, the chemical form most easily captured by currently available NOx and SOx emission control devices, as well as by mercury specific control devices currently under development. Since it is more cost-effective to reduce mercury emissions at these plants, they are more likely to install controls and therefore will have a greater relative impact on reducing mercury emissions and deposition. Finally, neither the Cap & Trade rule nor the MACT rule substantially lowers the highest deposition values that occur at locations in the Middle Atlantic and southern New England states, because the values at those locations are primarily influenced by emissions from municipal and medical waste incinerators.

CHAPTER VII NORTH CAROLINA'S TOTAL AND SPECIATED MERCURY EMISSION ESTIMATES

NC UTILITY BOILER CHARACTERISTICS

North Carolina is one of the leading electricity producing states with 46 coal-fired utility boilers with a total capacity of 13,300 megawatts (MW). Duke Energy and Progress Energy companies own and operate a combined total of 46 boilers at 14 power stations, accounting for 97 percent of NC's electrical generating capacity. In addition, there are eight coal-fired cogeneration boilers at four stations producing nearly 500 MW that are not covered under the CSA, but would be subject to proposed federal EPA requirements.

All the Duke Energy and Progress Energy boilers burn pulverized eastern bituminous coal and currently employ electrostatic precipitators (ESPs) as their only particulate matter (PM) controls. Most of these boilers were built before 1977 and are not subject to EPA New Source Performance Standards. As is typical in other states, there are a wide variety of boiler vintages (1950's to 1980s), boiler manufacturers (Combustion Engineering, Babcock & Wilcox, Riley), boiler design types (tangential-fired, wall-fired), and boiler sizes (40 to 1250 MW). Likewise, the existing ESPs reflect a wide variety of vintages (1950's to 1980s), manufacturers (Research Cottrell, Western Precipitation, Buell, and Environmental Elements), design types (cold- and hot-sides), sizes (sectionalization) from 3 to 6 fields; collection plate areas from 80,000 to 980,000 square feet), and some with, and others without, resistivity conditioning systems (sulfur trioxide or ammonia injection) on cold-side ESPs.

The state's two main electrical utility companies are mandated to significantly reduce NO_x and SO_2 emissions to the caps and schedule stipulated in the NC CSA. Each of the two major utility companies submitted their plans identifying the boilers being retrofitted with NO_x and SO_2 control technologies and the corresponding retrofit schedules. In contrast to the definitive CSA provisions with corresponding NO_x and SO_2 technology plans already made by the utilities, the new State law does not mandate any specific requirements or technology choices for mercury emission reductions. Instead, considerable mercury emission reductions from utility boilers are expected as co-benefits from to the specific reductions of NO_x and SO_2 emissions.

Table VII-1 presents a summary-level profile of the current and planned emission control characteristics of the NC coal-fired boiler population. One change in planned emission control occurred since last year: Progress Energy is not planning to install a FGD scrubber on the Lee Unit 3 boiler as previously intended. The characterization highlights include:

- 99 percent with advanced NOx combustion controls based on generating capacity,
- 79 percent with SO_2 scrubbers based on generating capacity; 87 percent with SO_2 scrubbers based on the amount of coal fired in Btu/yr,

- 68 percent with cold-side ESPs based on generating capacity, and
- 32 percent with hot-side ESPs based on generating capacity.

TABLE VII-1.
GENERATING CAPACITY STATISTICS FOR NO_X AND SO_2 CONTROLS ON NC COAL FIRED ELECTRIC UTILITIES

Utility	Advanced NO_x Control [1]	Generating Capacity and Percent Capacity with NO_x Control	SO_2 Control	Generating Capacity and Percent Capacity with SO_2 Control
Duke Energy (28 boilers with 8,192 MW total)	Total MW with Advanced Control	8,192 MW	Total MW with Scrubbers	6,217 MW
	Percent MW with Advanced Control	100 %	Percent MW with Scrubbers	76 % by capacity (87 % by use factor, trillion Btu/yr coal fired)
Progress Energy (18 boilers with 5,111 MW total)	Total MW with Advanced Control	5,013 MW	Total MW with Scrubbers	4,325 MW
	Percent MW with Advanced Control	98 %	Percent MW with Scrubbers	85 % (88 % by use factor, trillion Btu/yr coal fired)
Statewide (45 boilers with 13,303 MW total)	Total MW with Advanced Control	12,756 MW	Total MW with Scrubbers	10,542 MW
	Percent MW with Advanced Control	99 %	Percent MW with Scrubbers	79 % (87 % by use factor, trillion Btu/yr coal fired)

1. Technologies considered as advanced NOx controls include SCR, SNCR, NH_3 injection, or combustion modification.

Table VII-2 summarizes the NOx and SO_2 control technologies and operational schedules selected for each of the 14 power stations by the two utility companies to comply with the CSA requirements. A few rather minor changes in FGD installation schedules were made. Also included in Table VII-2 are the stations' generating capacity and general type of ESP. To the extent possible, the table reflects the tendency in installing:

- SCRs on some of the largest boilers early in the schedule (2002-2004) and SNCRs on the medium sized boilers later in the schedule (2003-2009), and
- FGD wet and dry scrubbers on the medium and large boilers (200-1250 MW) across the schedule (2005-2012).

These trends tend to maximize cost-effectiveness and accelerate air quality improvement for the affected period (2002-2012).

2. Number in parenthesis identifies boiler unit(s) equipped with corresponding emission control technology.

PRELIMINARY ESTIMATE OF TOTAL MERCURY EMISSIONS FROM NC UTILITY BOILERS

In 1999, the U.S. EPA conducted the Electric Utility Steam Generating Unit Mercury Information Collection Request (EU/ICR) to gather comprehensive information about mercury emissions from the coal-fired electric utility industry. This effort included collection of speciated Hg (elemental, oxidized, and particle-bound Hg species) emission control tests using the Ontario Hydro measurement method on 80 utility boilers. Recently validated by EPA and the utility industry, the Ontario Hydro method has become the

official method for measuring speciated Hg emissions from coal-fired utilities. The tests measured Hg rates in the coal feed to the boiler, and speciated Hg concentrations in the gas streams entering and exiting the emission control device. In addition, it also collected data on each of the roughly 1100 boilers in the United States of the important coal characteristics affecting Hg emission control. The coal data involved type, quantity burned, heating value, Hg, chlorine, sulfur, ash, and moisture content for the entire year of 1999. DAQ utilized each of the following tools to estimate Hg emissions from the existing and future planned emission control technology configurations for the NC coal-fired power plants.

EPA Hg Emission Estimating Tool

DAQ staff utilized appropriate data to calculate the estimated emissions for each boiler for the corresponding categories of NC utility boilers (see Appendix C). For the case of existing boiler configurations, two categories were utilized: cold-side ESP and hot-side ESP, each with bituminous coal, conventional dry-bottom pulverized boilers (Bins 1 and 4, respectively). For the case of future planned configurations, two additional categories were utilized: cold-side ESP with wet scrubber and hot-side ESP with wet scrubber, likewise each with bituminous coal, conventional pulverized boilers (Bins 10 and 11, respectively). The amount of Hg fed to each boiler was calculated from the 1999 EU/ICR data as the product of the amount of coal burned and the Hg coal content. Then the Hg emission level from each boiler was then calculated as the combined product of the following three factors:

- Amount of Hg fed to each boiler,
- Total Hg collection efficiency, and
- Relative percentage of each Hg species (elemental, oxidized, and PM-bound) in the emissions.

EPRI Hg Emission Estimating Tool

A similar engineering tool to develop *preliminary estimates* of speciated mercury emissions using site-specific information from electric utility boilers is available from the Electric Power Research Institute (EPRI).[51] While similar, the EPRI tool has three primary distinctions relative to the EPA tool.

- First, the EPRI tool sub-divides the 80-boiler EU/ICR emission database into only 11 categories. The data sets were grouped largely by emission control technology configurations, not by coal and boiler types.
- Second, EPRI's analysts concluded that the coal chlorine level was the dominant predictor of total and speciated Hg emission collection performance for all but one emission control technology (see third

[51] Electric Power Research Institute, "An Assessment of Mercury Emissions from U.S. Coal-Fired Power Plants," Final Report 1000608, October 2000.

distinction below). Given this correlation, they used regression analysis techniques to describe the relationship between coal chlorine level and Hg collection performance for 10 of the 11 categories of emission control technologies. This relationship predicts higher Hg emission control performance for increasing coal chlorine content. Coal chlorine is expressed in parts per million (ppm).

- Third, additional analysis indicated that for one emission control technology, namely cold-side ESPs, another chlorine-related factor, coal chlorine-to-SO_2 ratio, provided a better correlation with Hg collection performance than just coal chlorine. This relationship predicts higher Hg emission control performance for increasing coal chlorine/SO2 ratio. In this case SO_2 is expressed in lb/million Btu. [Limited copies of the report containing the EPRI tool are available to borrow from DAQ.]

In summary, EPA and EPRI used sound scientific principles in evaluating the EU/ICR database and in developing their respective engineering tools. DAQ considers both the EPA tool and the EPRI tool as viable means to estimate Hg emissions from the existing and future planned emission control technology configurations for the NC coal-fired power plants. Accordingly, DAQ has applied both tools to gain insight and understanding on the relative performance and emissions of existing and future planned emission controls on NC utility boilers.

NC Coal Composition

Both engineering tools recognize the importance of coal characteristics and emission control technology on the extent and control of mercury emissions. EPA divided up the EU/ICR data into coal types, and accounted for the amount of coal mercury. EPRI took another direction by accounting and correlating mercury control performance on coal chlorine composition or coal chlorine/SO_2 ratio. Table VII-3 presents coal composition data to show the favorable characteristics of the coal burned in NC electric utilities, including:

- Coal mercury content is slightly lower than the national average,
- Coal chlorine content is twice than the national average, and
- Coal chlorine/ SO_2 ratio is over three times more than the national average.

TABLE VII-3.
COMPARISON OF AVERAGE COAL BURNED IN NC AND USA ELECTRIC UTILITIES

Area	Coal Composition		
	Mercury, [1] lb/TBtu	Chlorine, [2] ppm	Cl/SO_2 Ratio [3]
NC	6.5	1400	1000
USA	7.0	700	300

1. Mercury content expressed as pounds of Hg per trillion Btu.
2. Chlorine content expressed as parts per million (ppm).
3. Chlorine to SO_2 ratio expressed as chlorine ppm per SO_2 ppm.

EMISSION ESTIMATES USING THE EPA AND EPRI TOOLS

Based on using input data from the 1999 EU/ICR, DAQ staff calculated the estimated emissions for each boiler for the corresponding categories of NC utility boilers using Excel spreadsheets. Table VII-4 compares the total Hg collection efficiencies delineated by emission control technology produced separately by the EPA and EPRI engineering tools. In three of the four emission control categories for existing and planned configurations, the EPRI tool predicts higher total Hg collection efficiencies than the EPA tool. Only in the case of Cold-side ESP followed by a FGD scrubber did the EPA tool predict a higher total Hg collection efficiency than the EPRI tool. Given the EPA predictions are based on a category average for each coal type, one performance number within a given coal/boiler/emission control type is developed, independent of coal chlorine content. The EPRI predictions are based on coal chlorine content or coal chlorine/SO_2 ratio. Consequently, there is a range of performance numbers developed, depending on the corresponding range of values of these two coal composition factors for the coals combusted in NC. Given that the EPA and EPRI tool developers took different directions in analyzing the available database, it is not surprising that performance levels for comparable control technologies did not turn out exactly the same.

TABLE VII-4.
MERCURY EMISSION CONTROL PERFORMANCE FOR EPA AND EPRI TOOLS

Emission Control Technology	EPA Tool [1]	EPRI Tool [2]
	Percent Total Mercury Removal, percent	
ESP Cold-side	29	40-48
ESP Hot-side	11	22-27
ESP Cold-side / FGD	78	65-70
ESP Hot-side / FGD	40	65

1. EPA prediction based on a category average for each coal type; one performance number within a given coal type is used independent of coal chlorine content.
2. EPRI prediction based on coal chlorine content or coal chlorine/SO2 ratio; a range of performance numbers is used depending on the corresponding values of these two coal composition factors.

Table VII-5 and Figure VII-1 present the results of the statewide mercury emission estimates for the current and future planned emission control configurations produced by using the EPA and EPRI tools. These two graphics show that:

- Nearly the same level of coal mercury feed levels as input to the boiler for both the EPA and EPRI tools of roughly 4,100 lb/yr.

- Modest emission reductions for the current set of emission controls; the EPA tool predicts nearly 3,000 lb/yr Hg emissions and 25 percent emission control, which are considerably higher than the EPRI tool predicting roughly 2,400 lb/yr Hg emissions and 42 percent emission control.

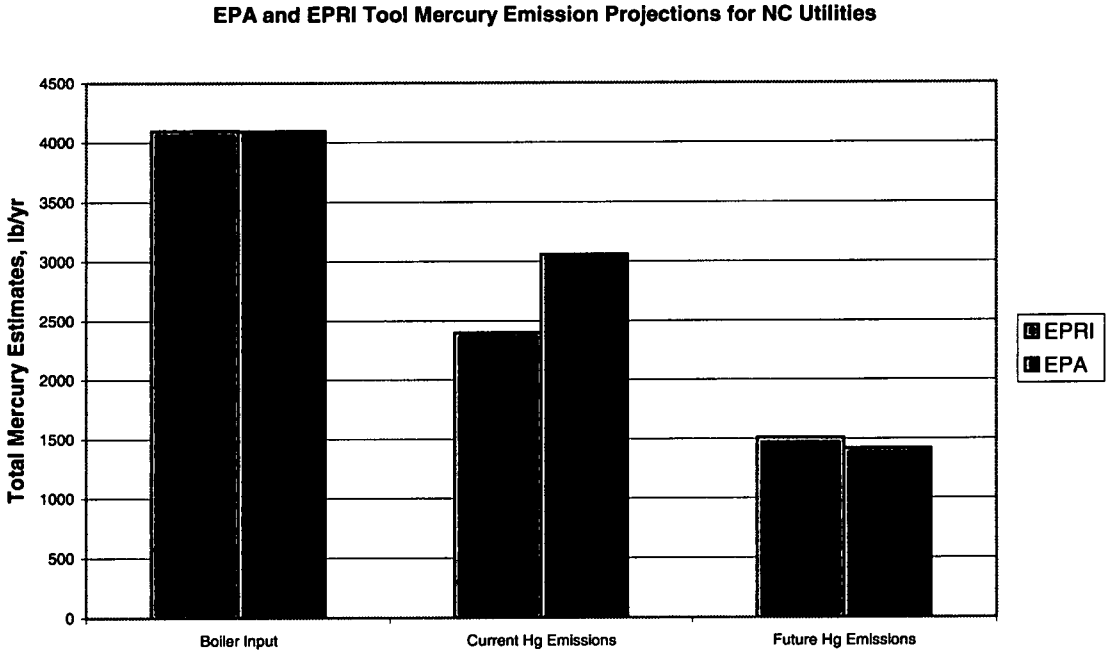
- Significant emission reductions for the future planned set of emission controls; the EPA tool predicts approximately 1,400 lb/yr Hg emissions and 65 percent emission control, comparable to the EPRI tool predictions of approximately 1,500 lb/yr Hg emissions and 64 percent emission control.

TABLE VII-5.
MERCURY EMISSION ESTIMATE PROJECTIONS
USING EPA AND EPRI TOOLS FOR NC ELECTRIC UTILITY BOILERS [1,2]

Tool	Total Mercury Levels				
	Boiler input, lb/yr	Emissions, lb/yr		Removal, %	
		Current	Future	Current	Future
EPA	4094	3057	1417	25	65
EPRI	4096	2397	1487	42	64
Average	4095	2727	1452	34	64

1. Projections assume the same coal supply and electric generation levels as 1999.
2. Estimate reflects average of EPA and EPRI tools.

FIGURE VII-1.
TOTAL MERCURY EMISSION PROJECTIONS FOR NC ELECTRIC UTILITIES
USING EPA AND EPRI TOOLS

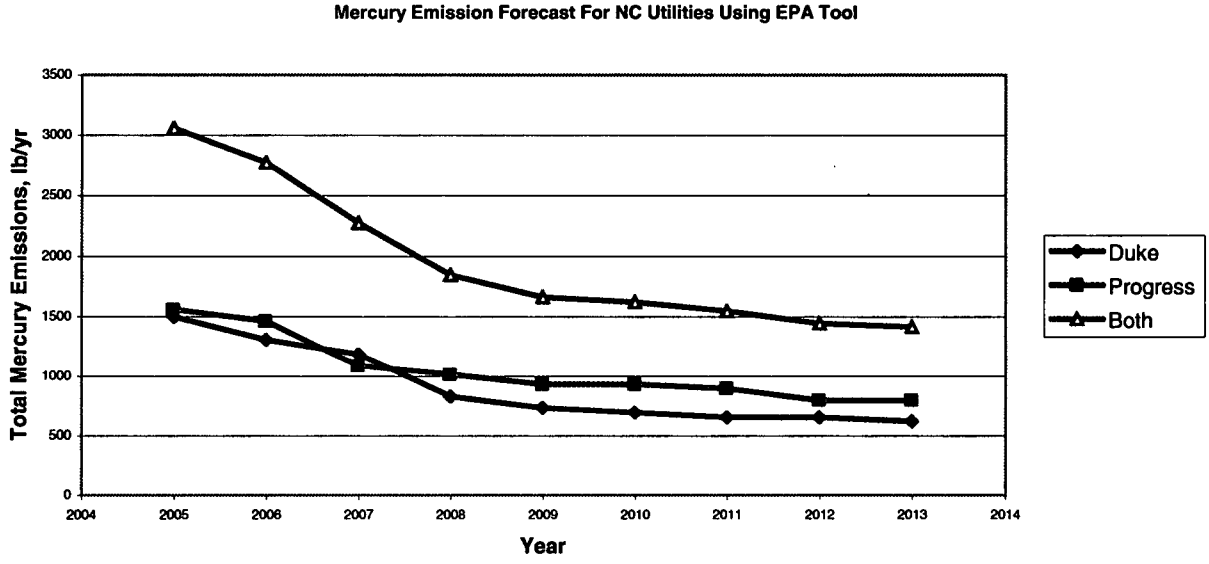


TOTAL MERCURY EMISSION FORECAST

The mercury emission estimate results from utilizing the EPA tool were applied with the SO_2 scrubber operational plans presented in Table VII-2 for forecasting emission reductions from 2005 – 2013. For the purpose of these future projections, it was assumed that the emission reductions from installing scrubbers would be fully effective during the year the utility company planned to install the equipment. This assumption was based on the general prediction that, on balance, the scrubber would become operational near mid-year and the boiler would be non-operational with no emissions for approximately a two-month period during equipment tie-in.

Figure VII-2 shows three graphs illustrating the estimated total mercury emissions for Duke Energy, Progress Energy, and the sum of both utilities. Note there are more emission reductions (reflected by the relatively steeper slope of the emission graphs) during the first half of the period (2005-2009) than in the second half (2009-2013) for all three graphs. Similar to the SO_2 case, this is due to the fact that each utility tends to install scrubbers on their largest units first, thereby achieving the largest emission reductions in the first half of the SO_2 / NOx compliance period.

FIGURE VII-2.
MERCURY EMISSION REDUCTION SCHEDULE FOR
NC ELECTRIC UTILITIES USING EPA TOOL



PRELIMINARY ESTIMATE OF SPECIATED MERCURY EMISSIONS FROM NC UTILITY BOILERS

For the past several years, advancements in the study of mercury have evolved to include examining the three chemical forms or species in which it is released into ambient air. The three species include elemental, oxidized, and particle-bound Hg. Total mercury is the sum of the three species. The term *speciation* is used to denote the relative amounts of these chemical forms of mercury. A related term – *partitioning* -- is similarly used in describing the relative behavior or outcome of the sub-division of these three parts of mercury species. Each mercury species has its unique set of chemical and physical properties leading to distinctive traits in terms of reactivity, toxicity, and collectability in emission controls.

To begin understanding the complex behavior of mercury in and from coal-fired exhaust gas, it is now standard practice to measure the individual mercury species. Given the capture of mercury by emission control equipment is dependent on mercury speciation, virtually all mercury studies for the past 5 years recognize the fundamental importance of focusing on particular mercury species. Research programs now provide information, methods, models, and data to address the key questions dealing with Hg speciation. Studies characterizing collection performance of various emission control technologies, behavior and transport of plumes, and plume deposition entails mercury species. For example, in terms of their contrasting properties and behavior, recent studies show that:

- Bituminous coal produces more oxidized Hg than other coal types;
- Most conventional and emerging control technologies capture oxidized Hg and particle-bound Hg much more effectively than elemental Hg;

- Elemental Hg is relatively stable, stays suspended for long time periods and is the dominant of the three species in ambient airs sheds; whereas

- Oxidized Hg emissions are fairly reactive, become attached to particles or other gases, and tend to be deposited within 25-50 miles of release. Of the three species, it can be argued that oxidized mercury represents the most important species to control from a state perspective because of its tendency to be deposited within a relatively short distance of release.

Given this basic and profound significance, DAQ utilized the available tools to quantify not only total mercury, but also speciated mercury emissions. The additional effort proved worthwhile, as interesting and encouraging information was produced regarding speciated mercury emissions.

Table VII-6 shows average results from the EPA and EPRI tools for the current and future situations delineating total and speciated mercury emission estimates from the NC utility boilers. It depicts the relative collection performance of ESPs in the current case of emission controls. The data in the table confirms that ESPs do not collect any elemental mercury, only collect a small fraction of oxidized mercury, but collect the majority of particle-bound mercury. Similarly, it depicts the relative collection performance of adding wet scrubbers to the majority of the boilers (80 percent by capacity, 87 percent on Btu heat input basis) in the future case of emission controls. The data in the table reflects that scrubbers do not collect any elemental mercury, collect a very high fraction of oxidized mercury, and likewise collect the majority of particle-bound mercury. It also suggests that some of the oxidized mercury collected in the scrubber is converted over to elemental mercury in the scrubber water, and is re-emitted out the stack.

The top half of Table VII-6 reflects a mass balance. For the current case of emission controls, it shows that the:

- Amount of mercury in the coal fed to the boilers is 4,100 lb/yr;

- Total mercury emissions are 2700 lb/yr;

- Oxidized mercury emissions are 1800 lb/yr, comprising most of the total mercury;

- Elemental emissions are 800 lb/yr; and

- Particle-bound emissions are 100 lb/yr.

(In rounded numbers to the nearest 100 for readability purpose and to reflect the nature of estimated numbers)

For the future case of emission controls, it shows some similar and contrasting facts, including:

- The same amount of mercury in the coal fed to the boilers would be 4,100 lb/yr;
- Total mercury emissions would be reduced to 1500 lb/yr;
- Oxidixed mercury emissions would drop to 400 lb/yr;
- Elemental emissions would be expected to *increase* to 1100 lb/yr, accounting for the majority of mercury emissions; and
- Particle-bound emissions would be reduced to 20 lb/yr.

The bottom half of Table VII-6 describes the data in terms of the relative percentage of mercury species for the two time cases. This helps to show how the mercury species are partitioned. In the current case:

- (All percentages presented below are relative to the mercury fed to the boilers):
- Emission controls (ESPs) collect 33 percent of the mercury fed to the boilers;
- The remainding 67 percent are released as emissions:
- Elemental emissions being 20 percent;
- Oxidized emissions being 44 percent, accounting for the majority of mercury emissions and
- Particle-bound emissions account for only 3 percent.

TABLE VII-6.
MERCURY MASS BALANCE AND PARTITIONING FORECAST FOR NC ELECTRIC UTILITY BOILERS [1,2]

Mercury Mass Balance							
Time	Coal Hg, lb/yr		Mercury Emissions, lb/yr				Total
			Total		Elemental	Oxidized	PM	
Current	4095		2727		813	1808	106	
Future	4095		1462		1061	384	17	
Mercury Partitioning [3]								
	Coal Hg, %		Removed in Emission Controls, %		Distribution of Mercury Emissions, %			
					Elemental	Oxidized	PM	
Current	100		33		20	44	3	100
Future	100		64		26	9	0.4	100

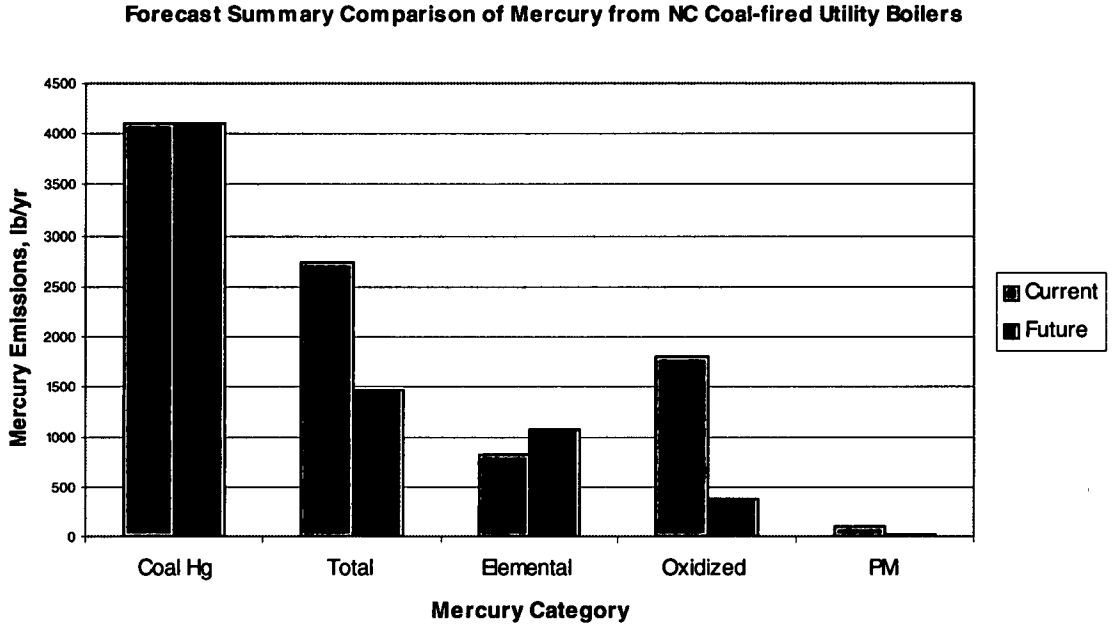
1. Projections assume the same coal supply and electric generation levels as 1999.
2. Estimate reflects average of EPA and EPRI tools.
3. Percentages presented are relative to the mercury fed to the boilers.

For the future case of emission controls, it likewise shows some similar and contrasting facts, including:

- Emission controls (ESPs and scrubbers) collect 64 percent of the mercury fed to the boilers;
- The remaining 36 percent are released as emissions:
- Elemental emissions would be expected to *increase* to 26 percent, accounting for most mercury emissions;
- Oxidixed emissions would drop to only 9 percent, and
- Particle-bound emissions would account for less than 1 percent.
  (All percentages presented above are relative to the mercury fed to the boilers)

Figure VII-3 graphically illustrates the same data as in Table VII-6 and can show the relative trends in total and speciated mercury emissions discussed above more readily for some readers.

FIGURE VII-3.
FORECAST SUMMARY OF TOTAL AND SPECIATED MERCURY EMISSION ESTIMATES FROM NC UTILITY BOILERS (REPRESENTS AVERAGE FROM EPA AND EPRI TOOLS)



Summary

Speciated data adds a new layer of valuable information regarding mercury emissions. Adding SO_2 scrubbers to most of the boiler capacity significantly deceases the amount of total mercury emissions from over 2700 to less than 1500 lb/yr. Of equal or possibly more importance, the addition of scrubbers reduces the amount of *oxidized* mercury emissions from over 1800 to less than 400 lb/yr. This means that only 9 percent of the 4100 lb/yr of mercury fed to the boilers (representing potential *oxidized* mercury emissions) is expected to be emitted in the future, a huge improvement over the current case of nearly 45 percent of boiler-fed mercury being emitted as *oxidized* mercury.

This significant reduction in *oxidized* mercury emissions suggests the possibility of considerable reductions in mercury deposition across NC. The exact amount of reduction in mercury deposition is unknown and considered controversial. The relative contribution of global versus statewide/local mercury emissions to atmospheric mercury deposition is poorly understood and remains an area of scientific debate. In general, there are two conflicting hypotheses:

- Hypothesis A. On one hand, roughly 90% of global mercury emissions come from abroad. Results of simulated modeling indicate that half of the mercury deposited in NC comes from abroad. This would suggest that even if NC could completely eliminate all its mercury emissions, there would only be a 50 percent drop in mercury deposition.

- Hypothesis B. On the other hand, data from the ongoing Florida study indicate a linear relationship between local emission reduction and deposition. This data suggests that any reduction in mercury emissions, especially *oxidized* mercury, will proportionally decrease local deposition and result in local environmental benefits within a few years. Accordingly, there could only be a nearly 2-fold or nearly 5-fold percent drop in mercury deposition, depending on whether the relationship is largely driven by total mercury or *oxidized* mercury.

Given that both engineering tools indicate similar performance levels, there is reasonable level of confidence in the expected emission reductions from adding scrubbers. These tools project emission reductions over current levels by nearly 2-fold for total mercury and nearly 5-fold for *oxidized* mercury. What is uncertain is whether Hypothesis A, B, or something in between applies in NC, and whether the relationship between emission reduction and environmental benefit is largely driven by total mercury or *oxidized* mercury.

CHAPTER VIII MERCURY CONTROL OPTIONS BEYOND CSA

OPTIONS UNDER THE CLEAN SMOKESTACK ACT ON THE DEVELOPMENT AND IMPLEMENTATION OF MERCURY STANDARDS AND PLANS

This report section is in response to Section 12 of the Clean Smokestacks Act (CSA) directing DAQ to study mercury issues. This Second Interim Report section includes a description of options that might be available in terms of standards and plans.

OPTIONS

This chapter discusses the rationale and plans to further study the complex and evolving science on mercury controls and effects. Included are three options with approximate dates for completion. We solicit the input of any and all interested persons concerning these or any other options.

- Option 1. Further study,
- Option 2. Set standards similar to those adopted or being considered by other states, or
- Option 3. Further study and then set standards, or
- Other sugested options.

OPTION 1. FURTHER STUDY; DEFER ANY RULEMAKING ACTION UNTIL A LATER TIME.

RATIONALE FOR FURTHER STUDY

First, as was the case when the CSA was signed in 2002, essentially all scientific information dealing with the benefits and costs of alternative strategies is still evolving, and is expected to continue evolving in the near-term. The federal government, electric power industry, and pollution control industry are advancing the technology and state-of-the-science on the measurement, control, fate, and health effects of mercury emissions.

Second, EPA is scheduled to finalize similar federal standards for controlling mercury emissions from coal-fired power plants in March 2005. The format of the federal requirements may add to the significant mercury emission reductions to be realized from the NC CSA.

Third, the relative impact of mercury deposition from local emission sources versus nearby states and the global "pool" is not fully understood; some data indicate that local sources have a profound effect, while other data suggest that emissions from abroad drive deposition. The different data makes it difficult to accurately predict mercury emission reductions and corresponding deposition from in-state power plants resulting from co-benefits of the NOx and SO_2 control device installations that will result from the CSA. It is also difficult to predict the effects from out-of-state areas from new EPA standards and/or NC's Section 126 petition urging emission reductions in 13 nearby states. In summary, it can be argued that it is too early and untimely at this point in time to

mandate any additional requirements beyond the CSA and the pending EPA standards for controlling mercury emissions from NC coal-fired power plants.

And fourth, NC appears to be the leading, or at least one of the leading, states in reducing mercury emissions from coal-fired power plants. This claim is based on our preliminary conservative projections that total and oxidized mercury emissions will be reduced by 65 percent and 90 percent, respectively, by 2013. These relatively high levels are consistent with the CSA, which stated that "[t]he General Assembly anticipates ... significant reductions in the emissions of mercury."

SCOPE FOR STUDY

There are no "hard" data available that clearly and unambiguously establish the relationship between Hg emission reductions from scrubbed coal-fired power plant and the local Hg deposition impact. Given this data gap and the state's apparent mercury-sensitive environmental properties, a comprehensive study is being planned to determine this relationship. DAQ has the experience for such a study, including speciated Hg ambient air monitoring, meteorological monitoring, wet mercury deposition monitoring, and dispersion modeling. Coincidentally, two NC coal-fired utility boiler stations have started constructing FGD scrubbers for operation in 2005-2007, providing opportunity to collect the above- mentioned set of Hg data before and after scrubber operation. The plants are Duke Power's Marshall Station and Progress Energy's Asheville Station. DAQ will collaborate with the stakeholders in preparing a study plan in the summer/fall of 2004.

Concurrently, it would be beneficial for the NC utilities to collect new, or share any already collected, total and speciated mercury emission data from some of the power plants. This would help better establish their current emission levels and provide sets of data to compare and validate the EPA and EPRI emission estimating tools data. It would also provide additional opportunity to evaluate an evolving list of emission control technology options.

Currently three technology options are considered possibly viable for NC utility boilers:

- Wet FGD scrubbers on boilers only equipped with cold-side or hot-side ESPs. Studies show that FGDs following cold-side ESPs have much higher performance and, therefore are more cost-effective, in mercury removal than those following hot-side ESPs.

- Carbon injection on units equipped with cold-side or hot-side ESPs. Currently, conventional activated carbon injection is considered only applicable on cold-side ESPs, even though carbon injection with fabric filters produce much higher performance than cold-side ESPs. Specially-treated carbons, such as brominated carbon, are the only sorbents currently viable on hot-side ESPs. Duke Power conducted a 1-week long brominated-carbon injection feasibility test at its Cliffside station in 2003;

results were encouraging enough that a 1-month long test is scheduled in 2004 at Duke's Buck Station with the same technology.

- Carbon injection with a fabric filter on units equipped with cold-side or hot-side ESPs. A full-scale continuous demonstration with activated carbon injection and fabric filter treating flue gas from a bituminous-fired boiler with hot-side ESP has shown the capabilities and limitations of the technology since July 2003. Mercury capture results show performance in the 70 – 90 percent range.

Several other mercury and multi-pollutant control technologies offer potential, but the promise of their performance has not yet undergone enough performance and reliability testing.

SCHEDULE

A comprehensive study could be completed in 2007 or 2008 by DAQ, pending resource availability.

OPTION 2. SET STANDARDS LIKE OTHER STATES

Option 2. Set standards like other states requiring mercury emission reductions on a percent basis (such as 40, 80, or 90 percent as in CT, IN, and WI), a thermal release basis (such as 0.6 lb/million Btu as in CT, IN, and MA), or a energy production basis (such as 0.0066 lb/MWhr as in NJ).

RATIONALE FOR RULEMAKING

Five states (CT, IN, MA, NJ, and WI) have mercury emission reduction standards in place or are already planning to propose mercury emission reduction standards. These states take the position that, while the science and technology are not fully developed, they are adequately developed to initiate rulemaking requirements. Federal mercury emission standards have been in effect on waste incinerators using carbon injection (the same control technology being successfully demonstrated at power plants) for several years. [For example, the municipal waste incinerator near Wilmington, NC has been using carbon injection for 3 years.] States with mercury standards believe that, since rulemaking has a history of forcing cost-effective technological developments, rulemaking will again be the engine for development. Rulemaking bodies in these states are convinced they have mercury problems with corresponding health effects. To them, common sense dictates that they must reduce mercury emissions from their largest sources. Lacking federal rules, these states have exercised or are planning to exercise their independence while setting an example for other states to follow.

SCHEDULE

DAQ projects that rulemaking in response to directions from the General Assembly could commence as early as 2006, with implementation occurring at least two or more years thereafter.

OPTION 3. STUDY FURTHER AND THEN SET STANDARDS.

Upon completion of the comprehensive study outlined in Option 1, DAQ would initiate a rulemaking development effort, similar to that described in Option 2.

RATIONALE FOR STUDY FOLLOWED BY RULEMAKING

Some argue that it is simply too premature and untimely to mandate additional requirements beyond the CSA now, based on the nature and extent of complex, evolving science, technology, and pending federal regulations. DAQ's conservative estimates indicate that significant mercury emission reductions are already expected as a co-benefit under the CSA. Further study as outlined in Option 1 is expected to improve understanding of the issues, along with results from many ongoing studies by federal agencies and the industry. It could be beneficial for all stakeholders to wait until additional information is available for additional future mercury control than to propose standards soon that may need to be revised (up or down) later.

SCHEDULE

DAQ anticipates that the studies could be completed in 2007 or 2008, allowing rulemaking to occur in 2008 or 2009, with implementation at least two years thereafter.

APPENDIX A
SCHEDULE OF PRESENTATIONS

Due to size of electronic files, these presentations are not included in the printed version of this report, but may be seen at DAQ's website: http://daq.state.nc.us/news/leg/2004-04-hg-co2-agenda.pdf

Monday, April 19

Introduction and Welcome
Keith Overcash, Director, NC Division of Air Quality, DENR

Background and Significance of Clean Smokestacks Act
Brock Nicholson, Deputy Director, NC Division of Air Quality, DENR

Purpose and Charge for this Workshop, Logistics, etc.
Jim Southerland, Environmental Engineer, NC Division of Air Quality, Planning Section

Basis for Issues to be Discussed: CO_2 and Mercury
Moderator, Sheila Holman, Planning Chief, NC Division of Air Quality

Review of the Science and Concerns for Climate Change in North Carolina
Ryan Boyles, Associate State Climatologist, State Climate Office of NC at NCSU

History and Transitions of the Global Warming Program and Policies in the US
Wiley Barbour, Environmental Resources Trust

Development, Components and Status of the NC State Energy Plan
Larry Shirley, Director, NC State Energy Office, NC Department of Administration

Health Effects of Methylmercury and North Carolina's Advice on Eating Fish
Dr. Luanne Williams, Toxicologist, NC Department of Health and Human Services

Recent NC Water Quality Mercury Monitoring Results
Michelle Woolfork, Water Quality Engineer, NC Division of Water Quality

Update on DAQ's Air Quality Measurements and Mercury Studies
Steve Schliesser and Todd Crawford, Toxic Protection Branch, NC Division of Air Quality

Lunch Speaker - Importance and Impacts of CSA Sections 12 and 13 and Your Input for the Future of North Carolina
Secretary William (Bill) Ross, NC Department of Environmental and Natural Resources

General Mercury Topics and Issues Session (Hg-1)
Moderator, Michael Abraczinskas, Environmental Engineer/Meteorologist, NC Division of Air Quality

Voluntary Mercury Reductions: NC Champions
Norma Murphy, NC Division of Pollution Prevention (P2), DENR

State of Science/Ability to Measure Mercury in Smokestack Environments
Barrett Parker, USEPA

Developing a Tool for Estimating Mercury Emissions and Reductions from Coal-Fired Utilities
Jeff Cole and C. Clark Allen, RTI International

Atmospheric Modeling and Deposition of Mercury from Stack to Sounds and other Water Bodies

O. Russell Bullock, Jr., Meteorologist, NOAA Air Resources Laboratory (on assignment to the EPA Office of Research and Development)

Historical Scientific Examination of Mercury Deposition to the Florida Everglades over the Past 100 Years or Atmospheric Mercury; Pandora's Box Revisited
Dr. Thomas D. Atkeson, FI DEP, Tallassee, FL, Robert K. Stevens, FL DEP (at US EPA, RTP, NC), and Matthew S. Landis, US EPA, RTP, NC

Tuesday, April 20

NC Specific Mercury Topics and Issues – Session 2 – (Hg-2)
Moderator, Steve Schliesser, Senior Environmental Engineer, NC Division of Air Quality

USEPA's Proposed Mercury MACT and Alternate Proposals for Mercury Reduction Trading Options
A Summary of Options and Schedule for Comments and Final Regulations
Bill Maxwell and Dr. Bob Wayland, USEPA

Performance and Costs of Mercury Control Technology for Bituminous Coals
Dr. Michael Durham, President, ADA Environmental Solutions

Achieving CSA System-wide Reductions in (NOx &SO_2) Emissions at Duke Energy Facilities and Reactions to Achieving EPA's MACT/Trading Proposals for Mercury (Including limited comments on options for new technologies, etc.)
Robert A. McMurry, Duke Energy

Achieving CSA System-wide Reductions in (NOx & SO_2) Emissions at Progress Energy Facilities and Reactions to Achieving EPA's MACT/Trading Proposals for Mercury
Ben White, Progress Energy

Estimated Emission Reductions in NC from Co-control as a Result of CSA, Using EPA Tool to Estimate NC Coal-Fired Power Plant Mercury Emissions
Steve Schliesser & Paul Grable, Environmental Engineers, NC Division of Air Quality

Developing Policy Options That Can Result in Integration of CO_2 and Mercury Reductions and State Implementation Plan Credits
Alden Hathaway, Environmental Resources Trust, Inc., Washington, DC

Lunch Speakers – Mercury and CO_2 Emissions from the Power Generation Sector
Dr. C.V. Mathai, Manager for Environmental Policy, Arizona Public Service Company, Phoenix, AZ

Insights from Economic Analyses of the Impacts to the Utility Industry from Mercury and CO_2 Controls, *Dr. Anne E. Smith, Vice President, Charles River Associates, Washington, DC*

Mercury Reduction Programs in Other States
Martha Keating, Air Toxics Scientist, Clean Air Task Force

General CO_2 Topics and Issues (CO_2)
Moderator, Phil Besesi, Project Manager, NC State Energy Office

Potential Impacts for the NC State Energy Plan on Emissions of CO_2 with Technical Procedures and Assumptions Upon Which These Plans Were Developed
Jeff Tiller, Appalachian State University

Technology, Energy Efficiency, and Renewable Energy for Emission Reduction
Ward Lenz, Director, Energy Programs and John Morrison, Vice President, Advanced Energy

The People, the Planet, and the Pocketbook: How a Green Builder Program Can Avoid Emissions Using Solar Energy
Dona Stankus, AIA, NC Solar Center

Potential in NC for Extraction of Wind Energy
Dr. Dennis Scanlin, Professor, Technology Department, Appalachian State University

LETTERS ADDRESSING PERCEIVED FLAWS IN PROPOSED STANDARDS OF PERFORMANCE FOR NEW AND EXISTING STATIONARY SOURCES: ELECTRIC UTILITY STEAM GENERATING UNITS

STAPPA/ALAPCO Letter

Concerning the "National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units: Proposed Rule,"

June 29, 2004

Docket ID No. OAR-2002-0056
EPA Docket Center (Air Docket)
U.S. Environmental Protection Agency
West (6102T), Room B-108
1200 Pennsylvania Avenue, NW
Washington, D.C. 20460

Dear Sir or Madam:

On behalf of the State and Territorial Air Pollution Program Administrators (STAPPA) and the Association of Local Air Pollution Control Officials (ALAPCO), thank you for this opportunity to comment on the "National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units: Proposed Rule," which was published in the *Federal Register* on January 30, 2004 (69 *Federal Register* 4652) and the "Supplemental Notice for the Proposed National Emission Standards for Hazardous Air Pollutants; and, in the Alternative, Proposed Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units," which was published in the *Federal Register* on March 16, 2004 (69 *Federal Register* 12398).

It is well known that mercury is a powerful neurotoxin that accumulates in the food chain and can cause damage to the brain and nervous system when ingested. In fact, because of methylmercury contamination, the U.S. Environmental Protection Agency (EPA), the Food and Drug Administration, 45 states throughout the country and other organizations, such as Health Canada, have issued fish consumption advisories to the public due to elevated concentrations of mercury. In January 2003, the Centers for Disease Control and Prevention estimated that nearly 8 percent of women of childbearing age are exposed to mercury levels that are above those considered safe for a developing fetus. More recently, EPA researchers have indicated that, based on examinations of umbilical cord blood, the estimate is closer to 15 percent.

In view of the dangers associated with exposure to mercury and other hazardous air pollutants, STAPPA and ALAPCO believe it is extremely important that EPA take swift and aggressive steps to reduce emissions of these pollutants from utilities and other source categories.

Unfortunately, for the reasons that will be described in these comments, STAPPA and ALAPCO are extremely dismayed with EPA's proposals to regulate hazardous air pollutants from electric utilities. We do not believe the rule will adequately protect public health and the environment, a concern that is shared by many others. For example, the Children's Health Protection Advisory Committee (CHPAC), a panel of experts that EPA formed to advise the agency on issues related to the protection of children's health, has expressed deep concerns with EPA's proposed rule. Specifically, CHPAC stated, "[f]rom our understanding, the unique vulnerabilities of children, infants, and women of child-bearing age were not adequately considered in the development of the EPA's proposed rule." Additionally, CHPAC indicated that the current proposal does not go as far as feasibly possible and "[t]o protect children from mercury exposure, EPA needs to go beyond the minimum required by statute (i.e., the proposed MACT floor)."

In view of our deep concerns and the objections other groups have expressed regarding the proposal, STAPPA and ALAPCO strongly urge the agency to abandon its proposed strategy and, instead, develop final Maximum Achievable Control Technology (MACT) standards, with stringent emission limits and expeditious deadlines, as required by Section 112(d) of the Clean Air Act. We have several major concerns with EPA's proposals, which we will articulate in this comment letter.

Flawed Emission Limits Under Sections 111 and 112

EPA has included several options for addressing emissions of hazardous air pollution from electric utilities, including proposals under Section 111, Section 112(d), and Section 112(n) of the Clean Air Act. We oppose all three options for a variety of reasons; most importantly, each is extremely weak and not sufficiently protective of public health and welfare.

We believe the Clean Air Act clearly calls for emissions of hazardous air pollution from electric utilities to be regulated under Section 112. Therefore, EPA's proposal to regulate those sources under Section 111, instead, is totally inappropriate. Furthermore, the limits contained in the Section 111 proposal are not nearly stringent enough. The proposal calls for an interim emissions cap – expected to be 34 tons per year – to be achieved by 2010 that, in fact, does not require *any* additional control of mercury beyond the co-benefits expected from other programs aimed at reducing emissions of sulfur dioxide and nitrogen oxide, such as the Interstate Air Quality Rule (IAQR). It appears, then, that the interim cap for mercury is wholly dependent upon the IAQR, rather than on any measures specifically designed to address hazardous air pollutant emissions. What would happen if, for some reason, the IAQR does not become final? Would the 2010 cap remain enforceable? Moreover, while EPA specifies a 15-ton final cap to be achieved in 2018, the agency acknowledges in its proposal that mercury

emissions could reach 22 tons (or only a 54-percent reduction from the 48 tons determined in 1999) in 2020, when banking and trading are utilized. Thus, EPA's stated 15-ton cap will not truly be achieved. We believe this does not adequately reflect what is technologically feasible and falls far short of what is needed to provide appropriate public health and environmental protection.

While we support regulating hazardous air pollution emissions from utilities under Section 112, as Congress intended, we believe EPA's proposals under Section 112(d) and 112(n) are seriously flawed. The EPA proposal sets MACT levels that would result in national emissions of 34 tons per year, which is clearly not consistent with the legislative mandate for calculating MACT under Section 112. Astonishingly, these levels are even less stringent than the recommendations made by industry representatives during an EPA-sponsored utility MACT development stakeholder process.

STAPPA and ALAPCO are extremely troubled by the statistical analysis regarding the variability of mercury content that EPA used in developing the proposed MACT standard. We believe the Clean Air Act is clear that EPA should base MACT for existing sources on the average of the top 12 percent of sources. We also believe variability in coal mercury content is adequately addressed in the annual averaging time of the standard. EPA's method for accounting for the variability of mercury content in coal is an inappropriate manipulation of the data. It resulted in emission limits that are far more relaxed than they should have been, based on the appropriate use of available data on well-controlled sources. Several state and local air agencies have conducted a thorough review of EPA's variability analysis and are providing the agency with specific comments regarding its inadequacies. We urge EPA to review those comments carefully. In light of our concern about the inappropriateness of EPA's variability analysis, we strongly urge EPA to develop the final MACT standard *without* the faulty statistical analysis the agency incorporated into the development of the proposal.

In addition to using a flawed variability analysis to develop the MACT standards, EPA failed to consider all available technologies. For example, activated carbon injection is commercially available and is widely recognized as a viable control technology for mercury. It has been demonstrated with pilot and full-scale demonstration projects on coal and has been used for over 10 years on other large combustion sources. Also, states are now requiring that activated carbon injection be installed on new coal-fired units for the control of mercury. In failing to consider available technologies like activated carbon injection, EPA has veered significantly from its past approach for developing mercury emission limits for combustion sources and has provided no justification for this dramatic change in the development of emission limits.

In previous MACT standards, EPA has not required technologies to be in long-term use to be considered "commercially available" and to be evaluated as a potential control method. Specifically, at the time EPA proposed the new source performance standards and emission guidelines for municipal waste combustors, activated carbon injection had been tested at only two facilities in the United States. Nonetheless, EPA justified the proposal to use activated carbon injection to set emission limits for mercury

"beyond the floor" because the tests showed lower mercury emissions to be achievable, and because the incremental costs to control mercury beyond the floor were low (59 *Federal Register* 48198 and 48228). EPA did not indicate that its deliberation was limited to control strategies the agency determined to be in long-term use when developing emission limits. Further, EPA continued to evaluate the applicability and efficacy of activated carbon injection when developing mercury emission limits at hazardous waste and medical waste combustors, even when this technology was rarely used at facilities.

EPA has not provided justification for considering coal-fired power plants in a different light. In fact, EPA has likely significantly frustrated the rapid and wide deployment of mercury control technologies by not considering their use for utility boilers, since the very act of EPA evaluating a technology as a means of developing an emissions limit drives the further development and installation of technologies.

EPA is undoubtedly well aware from its research that sorbent injection technologies, such as activated carbon injection, have been demonstrated to achieve significant mercury emission reductions at coal-fired power plants, regardless of coal-type. For example, a recent study by the Northeast States for Coordinated Air Use Management (*Mercury Emissions from Coal-Fired Power Plants* – October 2003) concludes, based on full-scale demonstration of activated carbon injection technology, that mercury control efficiency of above 90 percent is feasible (at costs similar to those of nitrogen oxide removal).

State and local permitting authorities have been relying on results from these studies to establish mercury emission limits in permits issued for the construction of coal-fired boilers. For example, Wisconsin is preparing to permit a coal-fired electric utility plant, using subbituminous coal, at 83-percent control efficiency.[52] Also, Iowa has issued a permit for a facility that will operate with subbituminous coal. That permit sets a limit of 1.7 lb Hg/TBtu, which is equivalent to an 83-percent reduction for operation with coal from the source with the highest average mercury content.[53]

Clearly, since a coal-fired power boiler operator holding a permit with mercury limits that rely on sorbent injection has commenced construction of a facility under that permit, the technology is clearly in commercial use, and thus must be considered in the development of mercury emission limits.

---

[52] Wisconsin Public Service Corporation Weston Unit 4 – 500 MW supercritical pulverized subbituminous coal-fired boiler; 1.7 lb. of Hg./TBtu controlled; 10.0 lb. of Hg./TBtu uncontrolled; 83% mercury control efficiency; sorbent injection/baghouse/dry FGD; sorbent not identified.

[53] MidAmerican Energy Company CBEC (Council Bluffs Energy Center) Unit 4 - 790 MW (estimated net) 7,675 MMBtu/hr heat input supercritical pulverized subbituminous coal-fired boiler; 1.7 lb. of Hg/TBtu (controlled); 10 lb. of Hg/TBtu (uncontrolled); expected control efficiency of 83% on coal with highest average mercury content; activated carbon injection with a minimum feed rate of 10 pounds per million cubic feet of exhaust gas. An optimization study required in which facility is to optimize control and can try other sorbents. Other controls - baghouse/selective catalytic reduction (SCR)/dry flue gas desulfurization (FGD).

Finally, EPA's proposal also includes an alternative MACT scheme that would allow for a cap-and-trade program similar to the proposal under Section 111. The preamble indicates that EPA would institute such a program under the provisions of Section 112(n) of the Clean Air Act. Section 112(n) calls for EPA to conduct a study for Congress describing the public health hazards resulting from utility emissions and describing control alternatives. Section 112(n) also states that "[t]he Administrator shall regulate electric utility steam generating units under this *section...,*" (i.e., Section 112) (emphasis added). It does not indicate that the regulations should be established under that *subsection* (i.e., subsection 112[n]). Sections 112(d), 112(f) and 112(h) of the Clean Air Act are the only subsections of Section 112 under which EPA is authorized to establish National Emission Standards for Hazardous Air Pollutants (see 40 CFR 63.2). Therefore, EPA is not authorized to establish emission standards under Section 112(n).

Recommended MACT Standard

As the Clean Air Act requires, EPA should establish a MACT standard that reflects *at least* "the average emission limitation achieved by the best performing 12 percent of the existing sources" or "the emission control that is achieved in practice by the best controlled similar source." Rather than recommending a specific technology, STAPPA and ALAPCO suggest a performance standard. Also, we prefer a common standard for bituminous and subbituminous coal, but different percent limits can be considered for the coal types, as long as the limits provide for very good controls of mercury emissions and do not promote fuel switching or blending to avoid controls (see discussion below). Accordingly, STAPPA and ALAPCO believe it is reasonable to consider 90-percent control for sources using bituminous coal and 80-percent control for units firing subbituminous coal. These limits would result in a national emission reduction between 85-90 percent, which is much more stringent than the decreases expected from EPA's proposal.

In summary, we do not believe EPA's proposal is appropriate or consistent with the requirements of the Clean Air Act. As we have recommended, the agency should calculate and establish a more stringent MACT level, in accordance with a proper reading of Section 112.

Coal Blending and Switching

We are concerned about the effects of fuel switching and blending under EPA's proposal. The proposed limits for subbituminous coal are so lax – in fact, they are tantamount to no control – that facilities may switch from bituminous to subbituminous coal or blend their fuels simply to obtain a higher allowable limit and escape stricter controls. The result would be higher emission limits and greater emissions of mercury. We recommend that the final rule address this problem by requiring a stricter emission limit for subbituminous coal (i.e., 80 percent). Additionally, EPA should require facilities that blend fuels to meet the most stringent emission limit that applies to whatever types of coal it uses.

Deadlines

We are very concerned that the deadlines in the Section 111 proposal are extremely protracted. While the settlement agreement under which EPA is operating calls for the agency to issue final utility standards for hazardous air pollutants by March 2005 (formerly December 2004), with compliance by December 2007, EPA's proposal postpones final compliance until 2018 and, as mentioned, would allow compliance to be delayed even further, perhaps for many years, due to banking and trading. We believe this extraordinary delay in compliance is inappropriate and counter to the mandate of the Clean Air Act and the settlement agreement.

The Clean Air Act requires that MACT be determined first and be no less stringent than the average of the best 12 percent of sources. The timing of compliance is to be a separate consideration. If, after the MACT determination is complete, it becomes evident that more than three years is required for all facilities to comply, additional time is available under Sections 112(i)(3) and 112(i)(4) of the Clean Air Act. If Congress had intended for EPA to always limit a MACT determination to what could be achieved in three years, it would not have provided these special extensions.

We recognize that the adoption of facility-by-facility controls with the effectiveness we are recommending represents a significant commitment on the part of many sources and may require more time than the traditional three-year compliance time period for MACT sources. Therefore, if needed, EPA can provide the extensions of time for compliance that are already available within the Clean Air Act.

Trading

STAPPA and ALAPCO are extremely concerned that EPA is proposing on a national basis to allow trading of mercury emissions between utilities. Not only do we question the legality of mercury trading, we are also very concerned that trading could lead to serious "hotspot" problems around the country.

While mercury emissions can travel great distances, some of the pollutant can also be deposited near its source. In fact, there is recent evidence that sources of mercury can have significant local impacts. In November 2003, the state of Florida published a study entitled, *Integrating Atmospheric Mercury Deposition with Aquatic Cycling in South Florida*, which estimated how quickly fish tissue levels respond to decreased regional mercury emissions. According to state officials, drastic reductions in the mercury concentrations in fish and wading birds in the Everglades "...are directly linked to the installation of technology that reduced mercury in emissions from industries in South Florida by a 100-fold during the last two decades." Additionally, according to a report of the New Jersey Mercury Task Force, which examined local emissions, models, and other studies, "it is likely that approximately half of the mercury that is deposited in New Jersey comes from relatively nearby sources." Thus, the concern about local sources causing local mercury hotspots must not be dismissed.

In the proposal, EPA has likened the mercury trading proposal to the acid rain trading program that is in place. Such a comparison is not appropriate because of the nature of the pollutants in question. While the acid rain program focused primarily on emissions contributing to welfare effects, the utility proposal focuses on mercury, which is a neurotoxin with serious health impacts. The two programs are not comparable.

EPA has proposed that any hot spots could be addressed through the adoption of more stringent state or local standards. While the adoption of more stringent standards by state and local agencies is a fundamental right that the Clean Air Act provides for almost all of its programs, the reality is not so clear-cut. Implementing more protective air quality measures is often unrealistic, if not impossible, for many areas. According to a survey that STAPPA and ALAPCO conducted, approximately one-half of state air pollution control agencies have restrictions on their ability to adopt programs that are more stringent than those of the federal government. Therefore, there is the very real possibility that EPA's proposal would result in hot spots that would remain unaddressed, endangering the population living in that area and the surrounding environment.

We have reviewed the trading program EPA outlined in both the proposal published in the *Federal Register* on January 30, 2004 and the supplemental notice on March 16, 2004, In light of the concerns we have raised regarding trading of mercury emissions between utilities, we recommend that EPA abandon this approach.

Additional Deficiencies of Proposed Use of Section 111

As stated earlier, STAPPA and ALAPCO believe EPA's choice of Section 111 as the vehicle for regulating emissions of hazardous air pollutants from electric utilities is highly inappropriate. By using Section 111 of the Clean Air Act to regulate mercury and nickel emissions from utilities, EPA has ignored other important statutory obligations under Section 112 of the Clean Air Act. For instance, EPA is disregarding the mandate to examine other hazardous air pollutants including, but not limited to, arsenic, chromium, cadmium, dioxins and hydrogen chloride. We strongly urge EPA to address emissions of other hazardous air pollutants in addition to mercury and nickel and to do so under Section 112.

Furthermore, while Section 112 requires EPA to evaluate and address the risks that remain eight years after a MACT standard is issued, Section 111 circumvents those requirements and does not mandate a future evaluation of residual risk. The Residual Risk program contained in Section 112(f) is a critical element of the Clean Air Act's efforts to protect public health against the dangers of exposure to toxic air pollution and should be applied to utilities, as it is to other sources of hazardous air pollutants.

STAPPA and ALAPCO strongly believe there is no justification for EPA to take such a huge legal risk by regulating mercury under Section 111 of the Clean Air Act when Congress clearly intended that mercury, like other hazardous air pollutants, be regulated under Section 112. Adoption of a Section 111 rule will undoubtedly be the

subject of protracted legal battles, which will further delay the protection of public health and the environment.

Finally, we are concerned that the use of Section 111, rather than Section 112, will result in a process similar to the State Implementation Plan (SIP) system currently used for Criteria Pollutants. That is, each state or local agency will be required to develop a plan, submit it to EPA, and await approval. Rather than a uniform national approach to regulating HAP emissions from utilities, which Section 112 would provide, the result of a Section 111 regulation would be a time-consuming process, a duplication of effort by each state and many local agencies, and an inconsistent set of state-by-state programs.

Process for Developing the Proposals

We feel compelled to comment on the process EPA used to develop these proposed standards. STAPPA and ALAPCO representatives were involved in the formal, one-and-a-half year Federal Advisory Committee Act (FACA) stakeholder process that EPA sponsored to develop the utility MACT. The FACA workgroup consisted of federal, state, local, industry and environmental group representatives, including six members representing state, local and tribal agencies; eight members representing environmental organizations; 14 members representing industry; one member representing control equipment vendors; and two members representing coal interests, producers and unions. This group met 14 times over a period of 18 months and thoroughly analyzed all issues related to the regulation of toxic air pollution from utilities.

In its January 30, 2004, proposal, EPA completely disregarded the stakeholder group's deliberations. For example, during the stakeholder process, the group never considered the possibility of substituting Section 111 for Section 112. In addition, the FACA workgroup dismissed the possibility of trading mercury emissions between utilities. Furthermore, upon completing the process, the workgroup requested that EPA complete integrated planning modeling based on the workgroup's final recommendations. EPA has failed to do this. It is unacceptable that EPA would abandon the efforts of the agency's FACA workgroup and propose a rule that represents such a marked departure from what the stakeholders considered and recommended. In addition to rejecting the expert advice the agency needed, EPA's action undermines and devalues the entire FACA process.

While we were extremely disappointed that the recommendations of the FACA workgroup were ignored, we were absolutely astonished to learn that the proposals EPA issued contained evidence of excessive reliance on industry input. For example, we noted that portions of documents supplied by an industry group and a law firm representing industry clients appeared verbatim or in nearly identical form in the proposals. This does not reflect an open process that takes into account the recommendations of the other stakeholders.

Conclusion

In light of all of these serious concerns with EPA's proposed regulations for limiting hazardous air pollutant emissions from utilities, STAPPA and ALAPCO strongly urge EPA to abandon its proposed strategy, and, instead, develop final MACT standards with stringent limits as required by Section 112(d) of the Clean Air Act. We continue to believe that the adoption of MACT standards for utilities is necessary and appropriate to protect public health and the environment.

North Carolina Division of Air Quality Letter

June 29, 2004

EPA Docket Center (Air Docket)
U.S. EPA West (6102T)
Room B-108
1200 Pennsylvania Avenue, NW
Washington, D.C. 20460
Attention Docket ID No. OAR-2002-0056

To Whom It May Concern:

On behalf of the North Carolina Division of Air Quality (DAQ), I would like to offer comments on the U.S. Environmental Protection Agency's (EPA's) proposed and supplemental proposed rules addressing national emission standards for hazardous air pollutants (NESHAP) for mercury and nickel which were published in the Federal Register January 30, 2004 and March 16, 2004.

My comments focus on three areas: the health effects of mercury in North Carolina, a comparison of the EPA proposal with existing measures in North Carolina, and a discussion on the relationship between the EPA proposal and future steps required to be taken by North Carolina.

Health Effects of Mercury in North Carolina

Methylmercury levels in fish from eastern North Carolina continue to be elevated above all of the existing toxicological benchmarks provided by the federal government, including benchmarks by the Food and Drug Administration and the Environmental Protection Agency. The North Carolina Department of Health and Human Services has issued fish consumption advisories for three species of freshwater fish that may be caught from waters south and east of Interstate-85; this constitutes more than one half of the state. The Department of Health and Human Services has advised women of childbearing age and small children not to consume these three species of fish when caught from surface waters south and east of Interstate-85. Reduced consumption rates are recommended for the general public. This is a tremendous loss of use of surface waters and natural resources. What makes this all the more important is that the area of greatest concern with respect to methylmercury levels in fish tissue is also the area with the most economic difficulty. Much of eastern North Carolina is economically depressed due to the loss of jobs and many families have resorted to providing their own sustenance through increased fishing and/or hunting.

Studies conducted by the Division of Water Quality suggest that mercury and methylmercury levels in surface waters, and therefore in fish, will not reach benchmark levels without realizing mercury reductions in the atmosphere. Total mercury concentrations in rainwater are at or above levels that water quality agencies would seek

in order to restore the ability to eat locally caught fish without an increased risk of neurological effects. Water quality agencies would typically seek pollutant reductions from wastewater and stormwater when a loss of use occurs. In this case, most municipal wastewater facilities have already installed equipment that would reach the current level of best available technology for mercury removal. This is in spite of the fact that most municipal wastewater facilities also receive and treat rainwater prior to discharging back to surface waters. Clearly this is not a situation to which traditional Clean Water Act controls would apply.

Therefore significant reduction in mercury emissions to the atmosphere is necessary for public health protection. Also, the reduction in a national program must assure that all local problem areas with identified mercury issues benefit from the program.

Comparison of the EPA Proposal with Existing Measures in North Carolina

Recognizing these health concerns, North Carolina is moving forward to control mercury emissions. In 2002, North Carolina passed the Clean Smokestacks Act (CSA), which substantially cuts the state's coal-fired power plants emissions of multiple air pollutants that cause smog, haze and other pollution problems. Under the CSA, North Carolina's 14 coal-fired power plants will reduce their emissions of key pollutants. In particular, the CSA requires power plants to reduce:

Nitrogen oxide (NOx) emissions from 245,000 tons in 1998 to 56,000 tons by 2009 (78 percent).

Sulfur dioxide (SO2) emissions from 489,000 tons in 1998 to 250,000 tons by 2009 (49 percent) and 130,000 tons by 2013 (74 percent).

The pollution controls required under the CSA are projected, as a co-benefit, to reduce mercury emissions in North Carolina by more than 50 percent by 2012. The EPA proposals will not yield comparable reductions. Under the proposed MACT, the reductions projected are 29 percent until 2018 nationally. In addition, there is no guarantee of site-specific reductions due to EPA's proposed Cap-and-Trade system.

Relationship Between the EPA Proposal and the Future Steps Required to be taken by North Carolina

In addition, the CSA requires the DAQ to conduct a study of mercury emissions in the state, including "the development and implementation of standards and plans to implement programs to control emissions of mercury from coal-fired generating units." Attached to these comments is a copy of the first interim report, "Mercury Emissions and Mercury Controls for Coal-Fired Electrical Utility Boilers", dated September 1, 2003. DAQ's final findings and recommendations are due to the NC legislature no later than September 1, 2005.

We would encourage EPA to consider in its final rule the process North Carolina already has in motion for evaluating the health needs and available technologies for achieving additional mercury reductions. Given the significant early reductions from implementation of the CSA, North Carolina hopes EPA will pass regulations that require similar reductions in other States. Regional reductions in mercury are required to ensure speedy return to safe consumption of local fish by populations at risk.

To summarize my comments: (1) mercury is a significant health problem in North Carolina, (2) the speed and amount of reduction of EPA's proposal are less than those for North Carolina's own requirements, and (3) the EPA rule needs to offer explicit right and authority for States to deal with residual local issues and to avoid preempting State programs.

Thank you for the opportunity to comment and for your consideration of these comments in the development of the final rule. Should you have any questions on the comments, please contact Sheila Holman of my staff at (919) 715-0971.

Sincerely,

B. Keith Overcash, P.E.

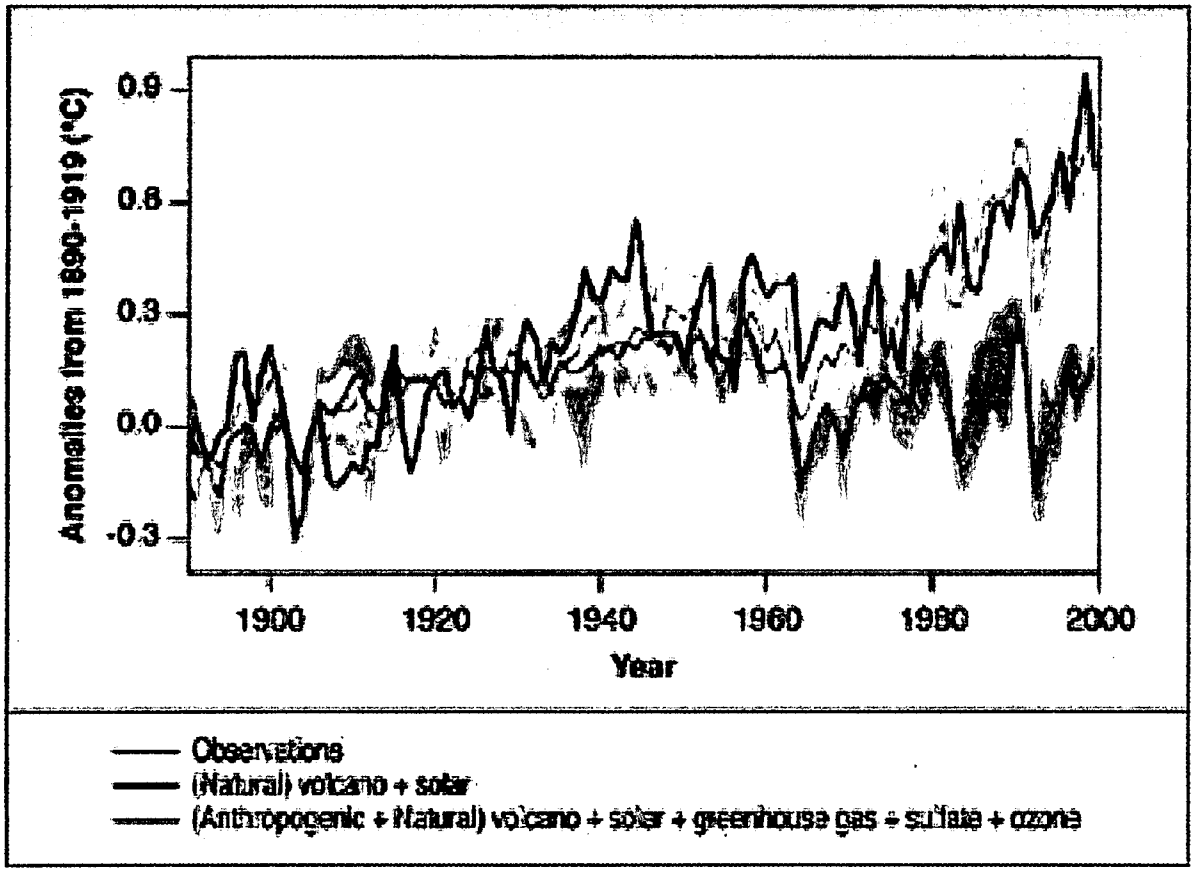
CO_2 Emission Reduction Options For Coal-fired Electrical Utility Boilers and Other Stationary Sources

September 1, 2004
Second Interim Report Pursuant to Clean Smokestacks Act

NCDENR



Source: CCSP/Meehl

North Carolina
Department of Environment and Natural Resources
Division of Air Quality

The Requirement: Excerpted from the Act

[Title: An Act to Improve Air Quality in the State by Imposing Limits on the Emission of Certain Pollutants from Certain Facilities that Burn Coal to Generate Electricity and to Provide for Recovery by Electric Utilities of the Costs of Achieving Compliance with Those Limits]

SECTION 13. The Division of Air Quality of the Department of Environment and Natural Resources shall study issues related to the development and implementation of standards and plans to implement programs to control emissions of carbon dioxide (CO_2) from coal-fired generating units and other stationary sources of air pollution. The Division shall evaluate available control technologies and shall estimate the benefits and costs of alternative strategies to reduce emissions of carbon dioxide (CO_2). The Division shall annually report its interim findings and recommendations to the Environmental Management Commission and the Environmental Review Commission beginning 1 September 2003. The Division shall report its final findings and recommendations to the Environmental Management Commission and the Environmental Review Commission no later than 1 September 2005. The costs of implementing any air quality standards and plans to reduce the emission of carbon dioxide (CO_2) from coal-fired generating units below the standards in effect on the date this act becomes effective, except to the extent that the emission of carbon dioxide (CO_2) is reduced as a result of the reductions in the emissions of oxides of nitrogen (NOx) and sulfur dioxide (SO_2) required to achieve the emissions limitations set out in G.S. 143-215.107D, as enacted by Section 1 of this act, shall not be recoverable pursuant to G.S. 62-133.6, as enacted by Section 9 of this act.

GENERAL ASSEMBLY OF NORTH CAROLINA - SESSION 2001 – (SENATE BILL 1078)
Ratified the 19th day of June 2002. (Ch. SL 2002-4 S.13)

CO_2 Emission Reduction Options For Coal-fired Electrical Utility Boilers and Other Stationary Sources

---

September 2004: Second Interim Report

Pursuant to the Clean Smokestacks Act of 2002

North Carolina
Department of Environment and Natural Resources
Division of Air Quality

An Invitation from Secretary Ross

TO: Environmental Review Commission
Environmental Management Commission

FROM: William G. Ross, Jr.

DATE: September 1, 2004

SUBJECT: Mercury and CO_2 Reports Required by Clean Smokestacks Act

On March 23, 2004, the United States Environmental Protection Agency recognized North Carolina and the Clean Smokestacks Act for outstanding, innovative efforts in improving air quality through regulatory and policy innovations and presented our state with a Clean Air Excellence Award. I had the privilege of saying a few words at the award ceremony in Washington, D.C., on behalf of our state, Governor Easley, and all the other partners who played vital roles in the passage of the law. It was a pleasure for me to describe the story of the Clean Smokestacks Act as a story about the power of innovation, partnerships, teamwork, and leadership.

The act, in addition to providing for major reductions in $S0_2$ and NOx emissions from NC's 14 coal-fired power plants, directed our Division of Air Quality, over a three year period, to study and make recommendations concerning emissions of mercury and carbon dioxide.

As you know, these are important, controversial issues. For example, Donald Kennedy, the Editor of *Science*, has called climate change "the most serious issue" we face.

Last year, 2003, the Division, working with a broad group of interested parties, put together reports reviewing and summarizing the state of scientific research on mercury and carbon dioxide emissions. This year, 2004, the Division has updated the review of research, and has inventoried options for the recommendations we must make next year (2005). We now ask all interested parties to read this year's report and give us their views, questions and suggestions about it.

> In the upcoming year, as we consider what to recommend, we will evaluate options for action with a number of criteria and principles in mind. As a starting point for those criteria and principles, we plan to use ones suggested in a report of a November, 2003 Aspen Institute policy dialogue chaired by Eileen Claussen and Robert W. Fri. The title of the report is: *A Climate Policy Framework: Balancing Policy and Politics.* As adapted for use in the task that the General Assembly has given us, the criteria and principles are as follows:

1. Environmental effectiveness: How effective is the option in meeting its environmental and public health and welfare target, whether that target is public awareness, information collection and evaluation, or emission reduction?
2. Cost effectiveness: Will the option design allow cost-effective compliance? How will it affect the ability of business to compete?
3. Administrative feasibility: Can the option be administered and does it minimize administrative and transaction costs?
4. Distributional equity: Is the burden of compliance with the option fairly apportioned?
5. Political acceptability: Are there elements of option design that affect its political acceptability?
6. Technology development and diffusion: Will the option help provide a platform for technology development and diffusion?
7. Adaptability: Will the option be able to adapt to changing circumstances and incorporate new information?
8. Monitoring and counting: Will the option include things that can be monitored and are verifiable?
9. Encouraging long term success: Will the option encourage long-term progress and success?

As I mentioned above, we invite your input with respect to whether these are the appropriate criteria and principles and how the various options for recommendations come out when judged against the appropriate criteria and principles. Also, we invite you to suggest options that are not in our inventory and to tell us why such options should be considered.

In the interest of giving every citizen of our State, now and in the future, a reasonable opportunity to live a happy, healthy, and prosperous life, we solicit your input and appreciate your help.

Preface

The North Carolina Clean Smokestacks Act (CSA), Session Law 2002-4 (aka Senate Bill 1078), was passed and signed into law in June 2002. This Act's primary requirements established reductions of SO_2 and NOx emissions from coal-fired power plants within the State. There were also two sections of the Act which require the Division of Air Quality (DAQ) to provide reports to the Environmental Management Commission (EMC) and the Environmental Review Commission (ERC) by September of 2003, 2004 and 2005, regarding the effects of these controls on mercury and CO_2 emissions. These sections also require DAQ to study and make recommendations to these bodies regarding any further actions needed for these two substances. The first reports (first interim) under this requirement were provided in 2003 and are available from DAQ's web page on the Internet at http://daq.state.nc.us/news/leg/. A summary of some of the main findings of that report follows this page.

The information in this Second Interim Report on CO_2 supplements and updates the information in the September 2003 report and attempts to define a range of options for future consideration (and should not be considered recommendations). Recommendations from DAQ will be addressed in the September 2005 report. The DAQ will continue the stakeholder process through the preparation of that final (September 2005) report. It continues to solicit input from stakeholders and all comments will be seriously considered. However, DAQ recognizes that it is responsible for all final recommendations, and reserves the rights to include, exclude, or revise the final documents to reflect its best judgment of facts, science and objectivity.

DAQ held a public workshop April 19-21, 2004 as a means of soliciting the latest available information, providing a forum for their discussion among stakeholders and others, and to generally exchange ideas on both CO_2 and mercury. A wide variety of speakers, many of whom are leading experts in their field, provided presentations. The presentation slides of the main points are provided on DAQ's web page and listed in Appendix A of this report. To view them, go to: http://daq.state.nc.us/news/leg/cleanst_hg_co_prov.shtml on your web browser and this will link you to those resentations. DAQ recognizes each of these speakers for their work and expresses its appreciation to each of them for their time and efforts to make these presentations and share their expertise.

Please note that in a few cases, text from some public domain (government) references may be repeated *verbatim* in this report for efficiency, expediency and accuracy. These situations are indicated. The intent is to give proper credit and use only public (copyright unrestricted) sources in these instances. If any errors or deviations to this intent are found, please immediately bring these situations to the attention of the authors. It is not the intent of the authors or DAQ to take credit for the work of others or disregard copyrights.

The authors and editors of this report express their gratitude for all contributors, stakeholders, reviewers and other interested parties who made it possible to produce this work.

Selected Conclusion Statements Extracted From First Interim Report

(See 2003 Report for further details at http://daq.state.nc.us/news/leg/)[1]

- Leading national and international science and governmental authorities, including the current administration, have concluded that man-made emissions contribute to climate change and that it is prudent to take rapid steps to reduce those emissions. The Bush Administration's "US Climate Action Report 2002"[2] accepts and supports the conclusions of the NAS report alluded to above.
- Despite the strong and growing scientific consensus, many still debate the severity of impacts from increased GHG, including CO_2[3], and what should be done in response to rising GHG levels.
- Climate change is a concern at all levels, from local to global, and must be addressed at local, state, regional, national and international levels, with coordinated leadership.
- Options for reducing GHG emissions include conservation, process changes, development and adoption of new technologies and other approaches at all levels of society.
- CO_2 is only one of several (usually identified as five major[4]) greenhouse gases that affect the climate, but the CSA could be interpreted to only address CO_2.
- The emissions of CO_2 in North Carolina from known sources have been quantified by multiple studies. These studies provide data that are acceptable for purposes of problem assessment. However, for emission trading purposes, the protocols and documentation standards required may cause these estimates to be less than fully adequate.

Other energy savings programs exist that contribute, or have the potential to contribute, to the reduction of GHG emissions. For example, the proposed **NC Energy Plan** is closely aligned and based on similar principles and objectives.

- Currently, substantial reductions in emissions of CO_2 are expected to come from energy efficiency improvements and other measures to reduce fuel consumption, as identified in the State Energy Plan.
- The recognized most effective way to "control" CO_2 is to reduce or refrain from burning of carbon-based fuels.
- Scrubbers that control or reduce NOx or SO_2 emissions are not effective in significantly reducing CO_2 and
- Several DOE (and other) research projects aim to
    - increase efficiency of utility boilers
    - capture/sequester CO_2 from stacks, and
    - control these gases by new and innovative methods (such as injection of captured stack effluent into deep underground coal seams or brine pools).

However, these have not yet been proven fully successful or economically viable.

Acronyms Used in This Report

AEFL - Amine-Enhanced Flue Lean Gas Reburn
CAA – Clean Air Act – Primary federal statute governing clean air requirements
CAFO – Confined Animal Feeding Operation
CAIR – Clean Air Interstate Rule
CAPA – Clean Air Planning Act – Carper Bill
CCAR – California Climate Action Registry
CCSP – Climate Change Science Program
CEM – Continuous Emission Measurement
CHP – Combined Heat and Power
CO_2 – Carbon Dioxide – the major global warming gas
CPA – Clean Power Act - Jeffords-Waxman Bill
CSA – North Carolina Clean Smokestacks Act (See inside cover for full text and title)
CSI – Clear Skies Initiative (or Act) – Proposal for revised CAA legislation by the Bush Administration (also recently referred to as synonymous with the CAIR)
DAQ – North Carolina Division of Air Quality
DENR – NC Department of Environment and Natural Resources
DOA – Department of Agriculture (US or NC)
DOE – The US Department of Energy
EPC – Energy Policy Council
EMC – Environmental Management Commission (NC)
EPICI – Electric Power Industry Climate Initiative
ERC – Environmental Review Commission (NC)
EPA – US Environmental Protection Agency
GHG – Greenhouse Gas(es)
GWP – Global Warming Potential
HFC's - Hydroflurocarbons
HVAC – High Volume Air Conditioning
IGCC – Integrated Gasification Combined Cycle
IPCC - Intergovernmental Panel on Climate Change, international authority on climate change
kWh – Kilowatt hour (1000 watts for one hour)
LNB – Low NOx Burner
LoGESO – Local Government Energy Savings Organization
NAAQS – National Ambient Air Quality Standards
NAS - National Academy of Science
NASA – National Air and Space Administration
NASEO – National Association of State Energy Officials
NC – North Carolina
NCCA – North Carolina Climate Action (Registry)
NCSU – North Carolina State University
NESCAUM - Northeast States for Coordinated Air Use Management
NHCPS – New Hampshire Clean Power Strategy
NSF – National Science Foundation
MOU – Memorandum of Understanding

MW – Mega-watt; millions of watts
NOAA – National Aeronautics and Space Administration
NOx – Oxides of Nitrogen, including NO_2, the primary nitrogen species from combustion
OFA – Overfire Air
PFC's - Perfluorocarbons
PTC – Production Tax credit
RGGI – Regional Greenhouse Gas Initiative (NESCAUM)
ROFA – Rotating Opposed-Fired Air
ROTAMIX – Injection of Ammonia to further reduce NOx (Used in combination with ROFA)
RPS – Renewable Portfolio Standard
SCR – Selective Catalytic Reduction
SCRUB – Wet scrubber for SOx
SEO – State Energy Office of NC
SEP – State Energy Plan of NC
SNCR – Selective Non-Catalytic Reduction
SO_2 – Sulfur Dioxide
SOx – Oxides of Sulfur, including SO_2, the primary combustion product of sulfur
SUV – Sport Utility Vehicle
TFS2000 – Combination Low-NOx Burner/Overfire Air
tpd – tons per day
UNFCCC - United Nations Framework Convention on Climate Change
WIR - Underfire Air

CHAPTER I EXECUTIVE SUMMARY

Introduction

The Clean Smokestacks Act (CSA) was passed and signed into law in June of 2002 by the North Carolina General Assembly and Governor Easley, respectively. This Act requires the Division of Air Quality (DAQ) to complete studies and make specific recommendations to the North Carolina Environmental Management Commission (EMC) and the North Carolina Environmental Review Commission (ERC) by September of 2003, 2004 and 2005 regarding CO_2 emissions from coal-fired power plants and other stationary sources. DAQ provided the First Interim Report to these two bodies in September of 2003. This Second Interim Report updates, and expands upon, the information presented in that report and begins to outline options that might be considered for recommendations in the 2005 report. Much of the information presented in this report was gained through additional literature searches and reviews and from information presented in a workshop held with stakeholders, national experts and interested parties in April 2004 (See Appendix A). DAQ continues to be open to new ideas and solicits your continuing input.

This Executive Summary is intended to list and highlight the range of options available from which to develop possible recommendations from which to choose for inclusion in the final report in 2005. This report does not make such choices this time. The process for reaching these decisions will include a continuing stakeholder process, expected to be reconvened in the spring of 2005. The remainder of this report provides additional discussion, details and highlights of options available. The intent is for the reader to use this Executive Summary to identify options and areas that they may wish to explore in more detail in other Chapters.

Main Findings in This *Second(2004) Interim Report*:

Some main points or findings summarized in this report are:

- According to the EPA, North Carolina ranks 14th among the states in total CO_2 emissions.[5]
- Our state's CO_2 output has grown steadily along with rises in energy consumption, increasing by more than 30 percent since 1990.[6]
- Currently more than 70 percent of North Carolina's energy comes from fossil fuels[7], and
- Residential energy consumption is expected to increase by about 50 percent by 2020.[8]
- Other GHG continue to be considered important in addition to CO_2.
- "End of Stack" solutions are not viable and practical for removal of CO_2 from stacks of power plants or other stationary sources at this time, but may be available over a longer term of several years.
- Costs of inaction to address climate change for North Carolina are projected by scientists and many others to be significant.

---

[8] North Carolina Energy Division, *North Carolina Energy Outlook, 2003*, Appendix Table, p. 92. Increase estimated from a 2000 baseline.

- A number of other states continue to take action on climate change in the absence of federal legislation. However, as this document was being finalized, the Bush administration made announcements regarding new affirmation that man's actions are definitely a part of the global climate change problem and that increased efforts to make reductions are appropriate. This announcement may spur new federal actions.
- There are potential benefits to various sectors of North Carolina's economy if the State is adequately prepared for the potential carbon marketplace, subject to the timing and structure of national carbon caps.
- There are also significant potential economic paybacks for non-utility sectors of the economy. Investments in development of an infrastructure to reduce carbon combustion (and other GHG equivalents) in other sectors will also help to assure that North Carolina is a leader in development and manufacture of new technologies. In so doing, industry and other institutions can be prepared to provide research, equipment, expertise and services to facilitate these needed changes occurring state-wide, nationally and globally.
- It is likely feasible to take positive actions to develop North Carolina procedures and processes that will result in a climate change registry process whereby the State will become part of a global solution with relatively minor impact upon public resources.
- Efforts and developments in the national, regional state and global arenas continue, (almost daily) and will necessarily influence choices of the next best and sensible steps for North Carolina.

Potential Option Levels for Satisfying the CSA Requirements

In light of the global and national momentum, and because of the risks and opportunities climate change poses for our state, many are convinced that North Carolina must prepare its economy and its people for a carbon-constrained world. Carbon dioxide and other greenhouse gas (GHG) emissions can be reduced by an array of solutions, including end-of-pipe technologies (now being researched), increased energy efficiency (such as encouraged in the State Energy Plan), greater use of renewable energy, carbon sequestration in trees and agricultural lands and incentives for lower emitting vehicles. Many of these steps can be implemented now. Some may need to be addressed later. Some solutions will likely need to be accomplished by adoption of new governmental policies; some with new State rules based on existing authorities, and others may require new legislation. Policy and legislative changes that are under consideration for the U.S Congress nationally will also likely have important impacts on efforts and steps in North Carolina, especially as needed to avoid redundancy and confusion.

This second interim report examines a wide range of options for reducing our State's GHG emissions and working with others to reduce the U.S. and global emissions. This report is thus intended to serve as an information source to aid DAQ, and stakeholders in developing recommendations for the North Carolina ERC and the EMC, as required by the CSA. Following submittal of this second interim report, the Division will begin developing an initial draft final report outlining proposed recommendations for North Carolina. That draft report is expected to be ready to begin stakeholder review by Spring 2005. Final revisions of that report, including final recommendations, will then follow by September 2005. The final recommendations will likely be developed from the list of options, or combinations thereof highlighted below, under five main groupings:

A. Take no action and default to potential federal and international actions to address the problem of requiring and defining means to achieve "CO_2 controls" (i.e. reductions) at some undetermined time in the future.

B. Commit to future actions, but only after further studies. This option would require the State to first undertake and complete additional studies and pursue more detailed analyses (requires new funding and other resources) involving multiple State agencies and academic institutions to further refine the options and actions.

C. Take a moderately more aggressive approach of accounting and reductions that would be designed with a combination of voluntary and required steps to maximize reductions in GHG, in conjunction with energy efficiency measures that result in a minimum of cost impacts.

D. Develop aggressive plans and take actions to set a cap on all GHG emissions; with reference and focus toward CO_2 from coal fired boilers, other stationary sources (combustion-centered, primarily) and transportation sources. This option would involve a significant mandatory reporting and accounting system to would guarantee that North Carolina does its share of leading and attainment of international goals, using established national and internationally accredited protocols and data storage capabilities.

E. A combination of either, or both, of the two previous options, but developed and implemented as part of an integrated multi-state energy and carbon emission reduction (Climate Action) plan.

Some Candidate Actions to Achieve the Major Options Outlined Above:

The items listed below is not necessarily complete, but helps define a range of actions and programs that may be considered for components of the larger overall options outlined above to develop the final recommendations for September 2005:

1. Develop/implement caps for reducing emissions all GHG pollutants (expressed in carbon equivalents) from all major sectors in the State
2. Develop/implement requirements for improved fuel mileage from motor vehicles owned both by the State and by the public
3. Institute a program and target for across the board reductions in use of energy use by State government in North Carolina, with credits for these reductions being quantified and used for possible "cap and trade" programs within the State
4. Initiate a program and policy resulting in an incremental movement toward shifting all electricity purchased by the State government to be through the NC GreenPower renewable resources program
5. Develop and incorporate applicable GHG-friendly policies and requirements in to the State Implementation Plan revisions for ozone and particulate matter (PM 2.5) to the maximum level that is feasible
6. Develop processes and policies to implement new technologies such as IGCC at the earliest possible stage to maximize reductions and maximize efficiencies over the longer term, especially before anticipated replacement of existing power generation capacity in North Carolina
7. Develop/implement a meaningful and detailed emission registration requirement, eventually with third party verification and salable and tradable carbon credits, including strict tracking and accounting of all areas covered by the State Energy Plan, and including consideration for a sector for quantifying natural emissions
8. Develop policies, incentives and systems/programs to encourage complete conversion for using waste from animal operations to its maximum as an energy resource
9. Develop/implement innovative policies that encourage reductions in utility generation and emissions while providing incentives for utility companies to endorse and aggressively assist in achieving such reductions.
10. Maximize the application and effects of the State Energy Plan with tracking of each sector
11. Develop more extensive plans, policies and incentives for use of forest resources for sequestration and for renewable energy (while avoiding double counting)
12. Revisions in net metering limitations and support of passage of new net metering laws
13. Expand study and potential development of renewable and non emitting energy sources and policies related thereto for such categories as:
    a. NC GreenPower in both private and government sectors
    b. Solar
    c. Wind and "geo-power"
    d. Bio fuels, etc.

14. Develop and participate in implementation of significant multi-state energy and carbon emission reduction (Climate Action) plans, involving stakeholder processes where possible
15. Fund and otherwise encourage programs at North Carolina universities to develop energy efficient and carbon-minimized technologies for North Carolina and world markets
16. Aggressively pursue development and nurturing of energy and carbon minimization technology research and manufacturing developments, along with promoting these research programs and manufacturing industries in the state
17. Develop a North Carolina Climate Action Registry that involves mandatory reporting and targets, recognizes existing reporting avenues, and includes reporting by the State sources, all using State guidance and requirements for submittals, but with the DOE 1605 (b) registry being the depository (with a minimal reporting requirement for largest sources only – not geared toward a "State-run" trading system)
18. Develop a basis for an emission credits (trading) program to be administered by private sector resources and motivation
19. Develop further options and plans to integrate IGCC technologies into future planning for energy generation in the state with a future option for geological sequestration
20. Make major recommendations to the North Carolina General Assembly regarding how to potentially alter the utility planning process to allow or provide for earlier input with the earliest possible identification of opportunities for potential encouragement or requirement of new technologies
21. And other similar policies and processes that may be identified.

Blank

If a man will begin with certainties, he shall end in doubts, but if he will be content to begin with doubts, he shall end in certainties. - Sir Frances Bacon

CHAPTER II BACKGROUND - NORTH CAROLINA'S CSA AND CLIMATE CHANGE

The text of the Clean Smokestacks Act (CSA) Section 13 appears on the inside of the cover page of this report, for convenience. The reader may also wish to review the First Interim Report (September 2003) or the summary on page v of this report, for further background and "state of the science" discussions not repeated in this report.

Pollutant Definitions and Other Terminology

The text of the CSA directs the Division to study CO_2, which is by mass or volume, the largest quantity of greenhouse gas (GHG) emitted by coal-fired utilities. It is also the largest effective component of the inventory of GHG emitted from all sources. However, as discussed in the First Interim Report other GHG, such as methane, N_2O, halocarbons, and others exist throughout the atmosphere and are contributory to warming of the oceans and Earth's atmosphere, with substantially more "warming effectiveness" per molecule than CO_2. For example, methane is 21 times more "potent" than CO_2. Other major contributors to atmospheric warming often overlooked and not addressed in these discussions are water vapor and particulate matter. Recent information provides evidence that "black carbon" particulate matter and nitrogen oxides, such as emitted from diesel vehicles, make significant contributors to climate change.[9] The Intergovernmental Panel on Climate Change (IPCC)[10] suggests that the effects of one ton of black carbon could equal that of about 200 to 600 tons of carbon dioxide when translated to temperature impacts. Although this document uses other GHG terms in places, the distinct identity and focus on CO_2 has also been retained for reference and completeness. Figure II-1 provides a pictorial representation of the relative impact of the various major GHG.

Figure II - 1[11]

A related terminology question also exists regarding global warming gases, GHG or "climate change gases." The terms are sometimes used almost interchangeably though there are variations in meaning. ["**Climate change**" specifically refers to changes in long-term trends in the average climate, such as changes in average temperatures. Depending on usage, it may mean changes due to natural factors and variability, or as a result of human activity. **"Global Warming"** refers to the progressive gradual rise of the Earth's average surface temperature thought to be caused, in part, by increased concentrations of GHG in the atmosphere.][12] In this document, we use the term "GHG" for convenience, though the more applicable term might be "Climate Change Gases."

In most sections, the CSA is specifically applicable to coal fired power plants. However, in the language of Section 13, the scope includes "other stationary sources." Therefore, the scope of this report and study effort is not limited solely to the utility industry and discussions refer to other major sources generating GHG, such as motor vehicles (which, of course, are not stationary).

Review of Concerns About Global Warming and Climate Change

As was stated in the First Interim Report, evidence has been accumulating that the Earth is warming and that this warming is occurring in close parallel to the levels of CO_2 in the atmosphere.[13]. Man made emissions of CO_2 have been increasing at a significant rate since the Industrial Revolution when the combustion of fossil fuels and other carbon fuels began to accelerate at a very rapid rate. Recent measurements show that atmospheric concentrations of CO_2 have been rising, and continue to rise at a rapid rate. Figure II-2 shows a plot of actual ambient concentrations of CO_2 at one of the most representative sites in the world at a high elevation in Hawaii. Similar relationships have been established with levels of CO_2 and temperature, as discussed in the First Interim Report.

Internationally, scientists have been discussing the growth of the CO_2 and other GHG in the atmosphere for many years and have been drawn into two camps regarding the effects of man made changes to a historic cycle of global warming and cooling. Various international scientific bodies and the National Academy of Sciences have concluded however, that the concerns for the impact of man-made emissions are warranted and that governments must take immediate actions to reduce these emissions. We must consider both the shorter term and the long term impacts of our actions and practices. These concerns and considerations have prompted efforts all over the globe to do something but it has not been well coordinated or orchestrated for these actions to be universal and consistent. It is likely that a leadership role by North Carolina could help make a transition to a more aggressive set of reduction policies and actions, albeit not necessarily focused exclusively on the coal-fired electric power generation units. Even as this document was being prepared for final publication, the President announced additional information and agreement among scientists that man's role in the climate change phenomenon must be revised and further steps taken to mitigate the

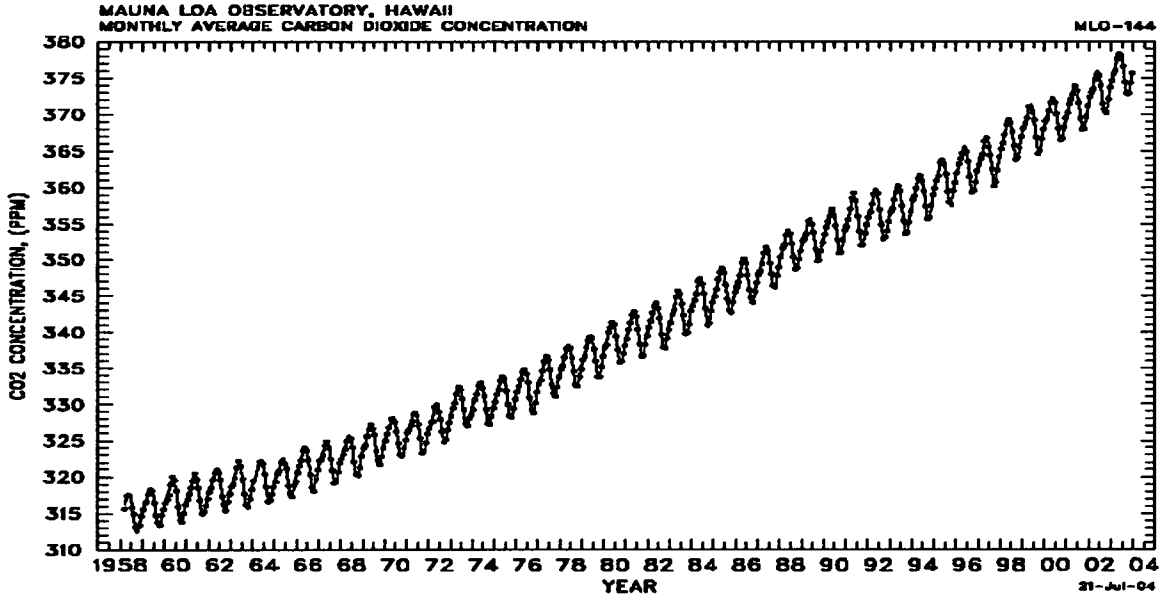
emissions of GHG.[14] In addition, new reports out of Europe have also defined more evidence of the changes taking place there and around the globe.[15]

Figure II-2

Atmospheric CO_2 Measurements from Mauna Loa Observatory (Since 1958)



A article by Leonard David, Senior Space Writer with NASA, recently summarized and commented on a National Research Council report: "Abrupt climate changes in the last few thousand years generally have been less severe and affected smaller areas than some of the changes further back in the past. Nonetheless, evidence shows that rapid climate changes have affected societies and ecosystems substantially, especially when the changes that brought persistent droughts occurred in regions with human settlements, there is no reason to believe that abrupt climate changes will not occur again."[16] The NRC report also underscored the importance of not being fatalistic about the threats posed by abrupt climate change. "Societies have faced both gradual and abrupt climate changes for millennia and have learned to adapt through various mechanisms, such as moving indoors, developing irrigation for crops, and migrating away from inhospitable regions." The study group added: "Nevertheless, because climate change is likely to continue and may even accelerate in the coming decades, denying the likelihood or downplaying the relevance of past abrupt changes could be costly. Societies can take steps to face the potential for abrupt climate change."[17] Figure II-3 below (also see

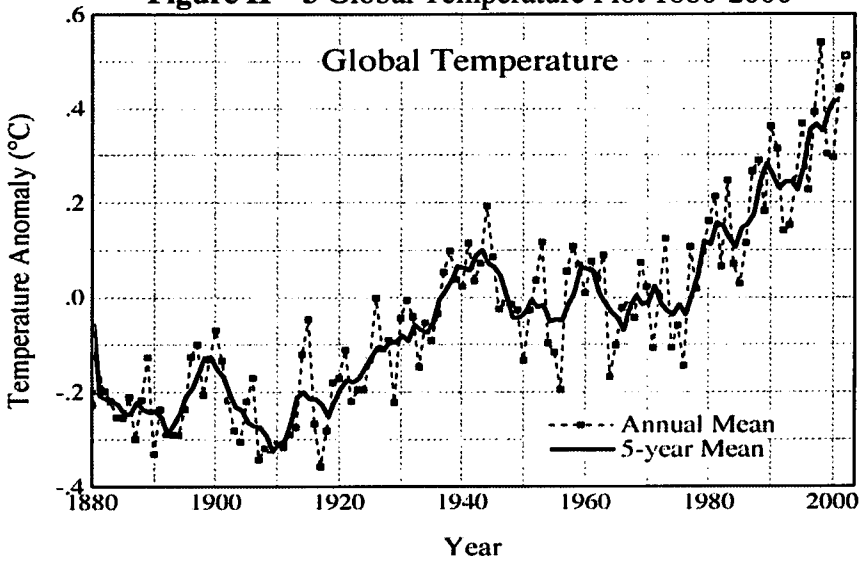
similar graph on cover), produced by NASA,[18] provides convincing evidence that the global temperature is increasing, even though the increments of change may seem small.

Figure II – 3 Global Temperature Plot 1880-2000



Eileen Claussen, President of the Pew Center on Global Climate Change, recently gave a talk on "Global Climate Change and Coal's Future." In this talk, she said "Warming by itself, of course, is not proof of global warming. Climate conditions vary naturally, as we all know, and I am sure you have heard arguments that such natural variability, whether caused by volcanoes or the sun, can account for the climate change we've seen in recent decades. But when scientists actually take a look at the relative importance of natural vs. human influences on the climate, they consistently come to the same conclusion. And that is this: observed climate change, particularly that of the past 30 years, is outside the bounds of natural variability. Atmospheric concentrations of carbon dioxide are more than 30 percent higher now than they were just a century ago. Despite what you may hear, this increase in carbon dioxide is undeniably human in origin, and it is the only way to explain the recent trends in the global climate."

Review of Sources of CO_2 in the U.S. and in North Carolina

For about a thousand years before the Industrial Revolution, the amount of greenhouse gases in the atmosphere remained relatively constant. Since then, the concentration of various greenhouse gases has increased dramatically. The amount of CO_2, for example, has increased by more than 30 percent since pre-industrial times and is still increasing at a rate of about 0.4 percent per year, mainly due to the combustion of fossil fuels and deforestation. Although natural emissions of CO_2 are significant, we know that this increase is anthropogenic because the changing isotopic composition of the atmospheric CO_2 betrays the fossil origin of the

[18] National Aeronautics and Space Administration, Goddard Institute for Space Studies, *Global Temperature Trends: 2002 Summation*, 2004. http://www.giss.nasa.gov/research/observe/surftemp/

increase. The concentrations of other natural radiatively active atmospheric components, such as methane and nitrous oxide (N_2O), are increasing due to agricultural, industrial and other activities. The concentrations of other nitrogen oxides (NO and NO_2) and of carbon monoxide (CO) are also increasing. Although the latter gases are not directly identified normally as GHG, they play an important role in atmospheric chemistry and GHG concentrations.[19]

Nationally, man-made emissions of GHG continue to grow, in spite of efforts and rhetoric to the contrary[20] (with residential leading the way with a 2.5 % annual growth in emissions). Although Duke Energy and Progress Energy, and other participants in voluntary GHG reduction programs, have proactively reduced their emissions substantially (from what they "would have been"), and are contributing to known reduction scenarios of over 266 tons/year,[21] these reductions do not offset growth. It is obvious that the reduction of statewide emissions in North Carolina will require actions for both transportation and electric generation and other sectors, to achieve success in reversing the slope of the North Carolina emissions trend line. Even then, it is important that the rest of the world follow the same pathways. Due to the large rates of growth of GHG emissions, immediate reductions to former "base case" conditions are not possible without application of new technologies or serious efforts to curtail the consumption (combustion) of fossil fuels. Other sources alone would not be able to achieve reductions on the order needed to reverse the growth trend to the level of 1990 or some earlier date or benchmark. To further exacerbate the situation, countries such as China are growing very rapidly and increasing their usage of, and emissions from, fossil fuels at a very rapid pace and their emissions contribute equally to global increases on a molecule by molecule basis.

Two of the largest source categories of man-made CO_2 in North Carolina are also coal fired power plants and transportation (automobiles, trucks, etc).[22] These two categories each make up in the neighborhood of 30 per cent of the total anthropogenic emissions, and both continue to grow.[23]

According to a recently released report from the DOE, U.S. energy-related CO_2 emissions in 2003 were up 0.9 percent from 2002 levels - from 5,736 to 5,788 million metric tons (MMT) of CO_2. Between 2002 and 2003, energy demand rose by 0.6 percent because high natural gas prices in 2003 resulted in a shift to higher carbon fuels, such as coal and petroleum, and a colder winter than the previous year, with a 3.8-percent increase in heating degree days, required more fuel (primarily natural gas) for home heating. CO_2 emissions in 2003 were below the 2000 level having fallen in 2001 by 1.8 percent and having grown by only 0.8 percent in 2002. [24]

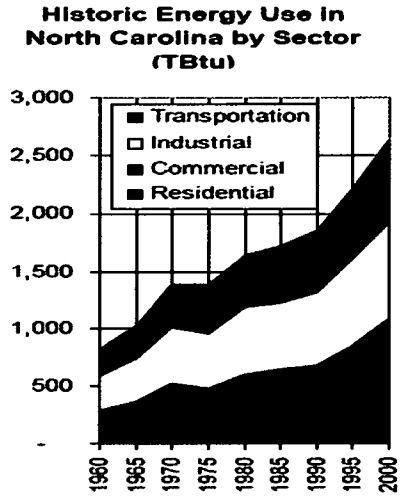
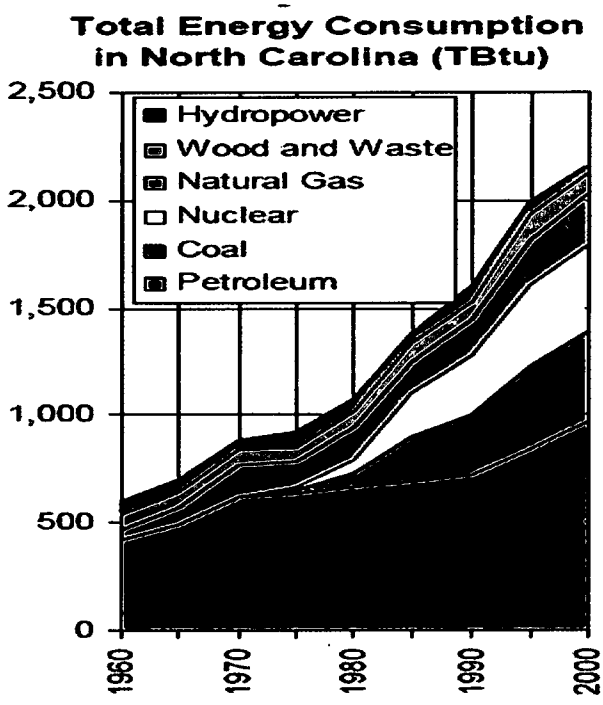
Figures II-4 and II-5 from the State Energy Plan provide graphic presentations of the distribution of energy consumption in North Carolina.

Figure II-4:



The largest single sector in terms of total energy use (including the energy consumed to generate electricity for the sector) is industrial at 31% of the total. Transportation is second largest with 28% of total energy use. The residential (23%) and commercial (18%) sectors, if combined, would demonstrate that the largest energy use in the state is in buildings at 41%.

Figure II-5



[25]

U.S. Energy-Related Carbon Dioxide Emissions

This report also shows that while coal produces the most CO_2 per unit of energy, petroleum produces a greater portion of the U.S. CO_2 emissions due to its larger consumption levels (transportation is a major component). Annual emissions growth from petroleum sources averaged 1.1 percent (1990 to 2003), annual emissions growth averaged 1.3 percent from coal and 1.0 percent from natural gas. In 1999, transportation-related CO_2 emissions overtook industrial emissions and remain the largest source of energy-related CO_2. Between 2002 and 2003, transportation CO_2 emissions grew 0.5 percent. Gasoline demand was up 1 percent, but a 35-percent increase in ethanol consumption helped to moderate direct emissions in the transportation sector. Between 1990 and 2003, transportation CO_2 emissions grew 19 percent (1.3 percent per year). Between 1990 and 2002, highway vehicle miles traveled grew by 32 percent (2.4 percent per year).

Between 2002 and 2003, residential CO_2 emissions grew by 2.5 percent as housing stock was up by 1.1 percent and heating degree-days were up by 3.8 percent. Between 1990 and 2003, residential sector CO_2 emissions grew by 28 percent (1.9 percent per year).

[25] North Carolina State Energy Plan, June, 2003, http://www.energync.net/State%20Energy%20Plan%2003.pdf.

This increase was driven by population growth of 17 percent (1.2 percent per year) and residential electricity demand growth of 39 percent (2.6 percent per year).

Between 2002 and 2003, CO_2 emissions from the commercial sector grew 1.3 percent as the economy grew by 3.1 percent and commercial employment rose 0.3 percent. Between 2002 and 2003, commercial sector electricity sales rose 0.4 percent, but CO_2 emissions rose 1.3 percent due to the higher carbon intensity of generation. Between 1990 and 2003, commercial sector CO_2 emissions grew by 33 percent (2.2 percent per year). This increase was driven by commercial sector employment growth of 32 percent (2.1percent per year) and commercial sector electricity sales growth of 46 percent (2.9 percent per year), again as stated in the DOE report referenced.

Between 2002 and 2003, *industrial energy-related* CO_2 emissions were unchanged; the index of total industrial output increased by only 0.2 percent. Between 1990 and 2003, energy-related industrial sector CO_2 emissions declined by 0.9 percent (-0.1 percent per year), while total industrial output grew by 44 percent and manufacturing output grew by 53 percent. By 2003, energy-intensive primary metals output was 1 percent below 1990 levels, while basic chemicals output was 6 percent below 1990 levels.

The energy quandary, as summarized by Eileen Claussen of the Pew Center for Global Climate Change in a recent speech, boils down to three questions. The first is energy supply (and therefore security) - can we find enough energy to meet our needs from sources that are secure? The second issue is climate change - can we provide the energy we need in ways that do not harm the climate? Last, but not least is the issue of cost or price - can we meet our energy needs in affordable ways that will allow us to continue to grow our economy? Looking across these three issues, it is clear that we need a climate-friendly energy policy on the one hand and an economy-friendly climate policy on the other. Some elements of these policies will be the same, but the important point is that we need to think broadly about how best to achieve the related goals of protecting the climate and meeting America's energy needs affordably in the decades ahead.[26]

For the electric generation sector, despite a 0.2 percent decline in generation, emissions increased by 44 MMT of CO_2 (2.0 percent) in 2003. Higher natural gas prices caused generators to switch to other, higher carbon fuels. Coal-powered emissions increased by 64 MMT (3.5 percent), while emissions from petroleum increased by 19 MMT (24.7 percent), and natural gas-powered emissions fell by 39 MMT (12.8 percent).

Of course, national statistics and conclusions do not translate on a one to one basis with the specifics for North Carolina, but the general trend and inclinations are similar. The emissions in the country as a whole affect the situation and conditions in North Carolina and the rest of the globe, though not necessarily on a straight line relationship. Figure II-

Weather and Climate Trends in the Southeast

Many climate changes have occurred over geologic history. Evidence of these trends exists in ice cores and other tools used by scientists to look back into the past. Analyses of recent data have shown[28] that temperature trends in the Southeast vary between decades, with a warm period during the 1920s through1940s, followed by a cooling trend through the 1960s. According to the cited reports, since the 1970s, temperatures have been increasing, with the decade of the1990's temperatures being as warm as the peaks in the 1920s and 30s. Annual rainfall trends show very strong increases of 20-30% or more over the past 100 years across Mississippi, Arkansas, South Carolina, Tennessee, Alabama, and parts of Louisiana, with mixed changes across most of the remaining area. There has been a strong tendency for more wet periods in the Gulf Coast states, and a moderate tendency in most other areas. Obviously, not all of these changes are due to human intervention. Changes in climate, by definition, occur over long periods of time, discounting year-to-year variations.

The cited report also summarizes that the Southeast is prone to frequent natural weather disasters that affect human life and property. Over half of the nation's costliest weather-related disasters of the past 20 years have occurred in the Southeast, costing the region over $85 billion in damages, mostly associated with floods and hurricanes. Across the region, intense precipitation events have increased over the past 100 years and this trend is projected to continue. The southern heat wave and drought of 1998 resulted in damages in excess of $6 billion and at least 200 deaths, not to imply that it was the result of or only the result of climate change from global warming.

Human health concerns arise from projected increases in maximum temperatures and heat index in the region. These concerns are particularly great for lower income households that lack sufficient resources to improve insulation and install and operate air conditioning systems. Air quality degradation in urban areas is also a concern associated with elevated air temperatures and increased emissions from power generation, which can increase ground-level ozone. The higher the temperatures, the more air conditioning that is used, further aggravating the situation. Increased flooding in low-lying coastal counties is also likely to adversely impact human health. Floods are the leading cause of death from natural disasters in the region and nationwide.

North Carolina Climate and Perspectives

The State Climate Office at North Carolina State University has studied changes in the state, and in DAQ's April 2004 workshop session, information was provided indicating that they have concluded that changes do occur that are due to human intervention and activities.[29] Even surface reflectivity modification activities such as paving of highways and parking lots cause changes in atmospheric temperature, as do changes in crops and the vegetative cover from agriculture and forestry practices. Actions all over the globe impactson the climate in North Carolina. Conversely, actions in North Carolina similarly

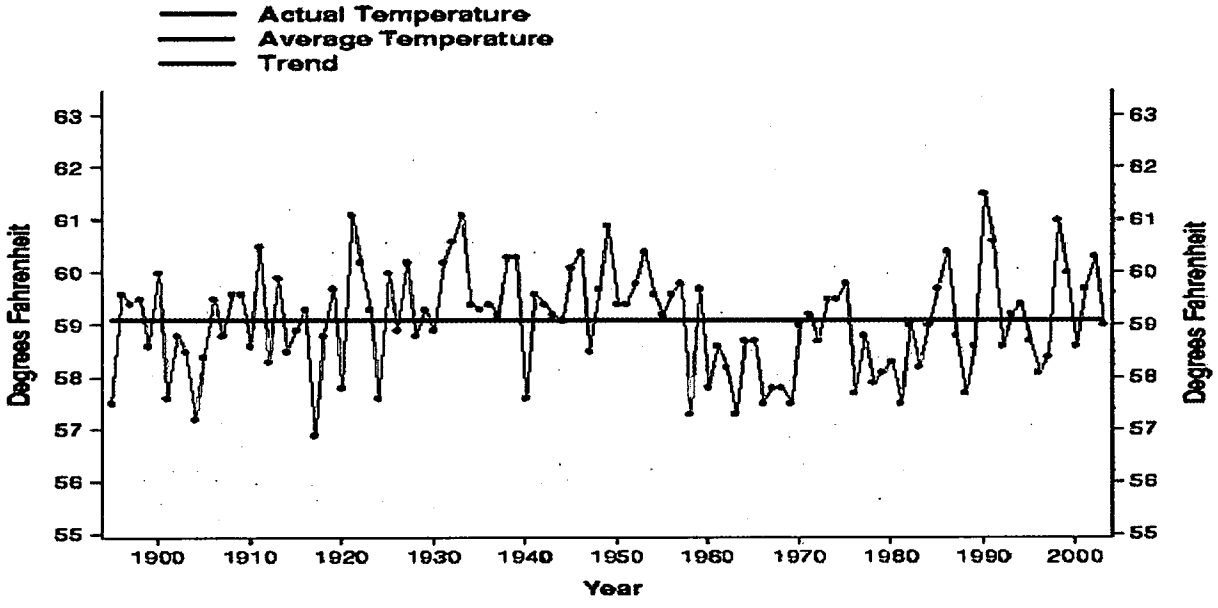
contribute to changes around the world. Very little association between real time changes in North Carolina emissions will be reflected in immediate and traceable change in the state, and little changes relative to the whole problem in the global sense. A 100+-year plot of temperatures in North Carolina from the National Climatic Center database (Asheville, NC) is shown in Figure II-8, showing a trend upward in recent years. Equally important are land use patterns, development, urbanization and changes in GHG.

Figure II-8
Statewide Average Temperature for North Carolina (1885-2004)
Source National Weather Records Center[30]



Implementing the CSA will result in reductions in sulfur dioxide (SO_2), and thus, the reduction of atmospheric sulfates. These sulfates result in formation of small particles in the air that also contribute to the greenhouse effect. As the CSA-required scrubbers are put on line and the reductions in SO_2 occur, the greenhouse effect is expected to be reduced somewhat by this effect. It is not possible to make this relationship quantitative, however.

The State Climate Office also indicates that there are good science reasons for North Carolina to begin to make reductions in GHG, including CO_2, and that it should start now.[31] The known science is represented through models, but the models are not sufficiently refined to be able to reflect all situations. However, the evidence and associations are strong. On the other hand, models and records allow for tracking of global changes over the past several years. These models don't make reliable predictions for the next 100 years, but can be accepted as directionally correct. They also do not do a

[30] National Climatic Data Center, *Climate at a Glance, North Carolina*, http://climvis.ncdc.noaa.gov/cgi-bin/cag3/hr-display3.pl.
[31] Bryan Boyles, Presentation to DAQ Mercury & CO_2 Workshop, April 19, 2004, Raleigh, NC (See Appendix A).

good job on local patterns, but are better for global changes. Precision is not good but general changes are directionally good. The projected numbers will likely continue to change over the next several years and decades.

North Carolina will be most vulnerable in the coastal areas if projections come true. Other changes may occur if warming and climate changes cause a migration of the "sweet spot" for growing various crops and natural vegetation. Some researchers[32] even project an increase in poison ivy, but again, this is speculation and not necessarily agreed to by all scientists and evidence.

If the global community does not reduce emissions of GHG significantly, some project that North Carolina will likely be left with a climate similar to that of central Florida,[33] a dramatically different coastline due to sea-level rise and subsequent inundation[34], an increased occurrence of heat-related asthma and death,[35] and hundreds of millions of dollars in losses from severe weather events.[36] However, it is argued that if sufficient reductions are implemented quickly, and globally, the costs associated with these impacts can be alleviated. At the same time, these actions can stimulate the State's economy, according to some advocates. Innovative, business-oriented policies that create a market for GHG, or equipment for their reduction will potentially align environmental goals with business goals and generate revenue is a strong argument for action.

CHAPTER III IMPACTS AND ECONOMICS OF CLIMATE CHANGE

It is not possible to provide an original, complete, authoritative discussion and analysis of all physical and economic impacts for North Carolina within the confines and limitations of this report and the information available. However, some general tendencies and observations can be made. That is the purpose and intent of this chapter.

A Backdrop of Growth in Southeastern States

The Southeast "sunbelt" continues to be a rapidly growing region with population increasing by more than 30 percent between 1970 and 1990. Much of this growth occurred in coastal counties with expectation that this growth will continue for the several years. The number of farms in the region decreased 80 percent between 1930 and 1997, but still produces roughly one quarter of US agricultural crops. The Southeast has become America's "wood basket," producing about half of America's timber supplies. The region also produces a large portion of the nation's fish, poultry, tobacco, oil, coal and natural gas. Prior to European settlement, the landscape was primarily forests, grasslands, and wetlands, but by 1920, most of the native forests were converted to managed forests and agricultural lands. Although much of the landscape has been altered, a wide range of ecosystem types exist and overall species diversity is high.[37]

Projected Climate Change Impacts

The United Nation's Intergovernmental Panel on Climate Change (IPCC) projects that, because of elevated concentrations of GHG in the atmosphere, the rate of sea level rise for the next 100 years is likely to be at least double the rate that we have experienced over the last century. The IPCC estimates that sea levels in the Atlantic Ocean are likely to rise 19 inches by 2100, and could rise by as much as 36 inches in the same period if GHG emissions go unchecked. If these projections are experienced, by 2030, there could be a 10-inch sea level rise along the North Carolina coast. The effects of potential further melting of the Greenland and Antarctic ice sheets are not included in these scenarios. Recent research suggests that this melting could have a faster and even more serious impact on sea-level rise than previously thought.[38, 39, 40] Of course, not all scientists are in agreement with these conclusions or projections, but the consensus continues to grow.

Tools such as climate models are often used to integrate the complex interactions and effects to provide a basis for conclusions. Such climate model projections exhibit a wide range of plausible scenarios for both temperature and precipitation over the next century. Two commonly used models are the Hadley Model and the Canadian model.[41] Results of such models, though often challenged, are generally accepted as the best available basis for

[41] Ezra Millstein, *The Potential Impacts of Global Warming on the Southeast*, World Wildlife Fund, from the First National Assessment of the Potential Consequences of Climate Variability and Change, http://www.climatehotmap.org/impacts/florida.html .

projections and have been endorsed by the National Academy of Science.[42] Both of the principal climate models were used in the National Assessment project,[43] and both indicated warming in the Southeast, but at different rates. The Canadian model shows the Southeast experiencing a high degree of warming, which further translates into lower soil moisture as higher temperatures increase evaporation. The Hadley model simulates less warming and a significant increase in precipitation (about 20 percent). Some models suggest that rainfall associated with El Niño and the intensity of droughts during La Niña phases will be intensified as atmospheric CO_2 increases.

In addition to seal level rise, many areas along the North Carolina coast are believed to be sinking by about 7 inches per century. This means that some areas of coastal North Carolina may likely experience an accelerated rate of inundation, regardless of climate effects. A sea level rise (or sinking of the land mass) of less than 14 inches would likely inundate about 770 square miles of the North Carolina coast, an area nearly the size of Great Smoky Mountains National Park.[44] The State's coastal wetlands and other low-lying areas could be flooded, and the Albemarle and Pamlico sounds could become open waters. The North Carolina coastal areas are already some of the most vulnerable to extreme weather events in the U.S., and even low-intensity storms create billions of dollars in damage.[45] The combined effects of rising seas and sinking lands could drastically change much of our coastline and barrier islands, increase vulnerability to storms, and put billions of dollars of coastal property at risk.

Assuming these projections are fulfilled, traditional approaches such as flood levees, elevated structures, and building codes, will not be adequate alone to prevent or even manage damage in the coastal zone as sea level rise would continue to increase the threat of storm-surge flooding in virtually all Southeastern coastal areas. Improvements in risk assessment, coastal and floodplain management, linkage of insurance to policies for mitigating flood damage, and local mitigation planning might help decrease potential economic impact. Changes in climate and sea-level must be integral parts of coastal communities develop strategies for hazard preparedness and mitigation.[46]

Potential Economic Impacts Associated with Climate Inaction

Associating "real" economically defensible costs with any particular inaction is difficult and speculative at best. However, according to a report prepared for the United Nations Environment Program, "Worldwide economic losses due to natural disasters appear to be doubling every ten years, and have reached almost $1 trillion over the past 15 years. If current trends persist, the annual loss amounts as estimated by UNEP, will come close to US $150

billion within the next decade.[47] North Carolina's share of this estimate would also be difficult to assess. However, according to one report, in 2002, North Carolina experienced more than $678 million in weather-related losses and government expenditures.[48] This is not to imply a direct relationship with climate change, but there is certainly an expected connection.

Tourism has definite potential for economic impacts if the climate projections hold true, especially with regard to a rising sea level. In 2001, tourism in North Carolina's 20 coastal counties generated an economic impact of nearly $1.8 billion. Accelerated sea-level rise would threaten this revenue and billions of dollars worth of property.[49] The costs of health, agriculture and other related costs would likewise be large.

However, there are also potential benefits and opportunities associated with development of renewable energies, improvements in energy efficiency and related technologies in the state. According to California studies, renewable energy development can generate even more jobs than fossil fuel-based energy production on a common basis of megawatt delivered.[50]

Nothing affects the business climate of a company as much as making a profit, or not. That is a basic reason why the company exists and is in business. If the environmental, such as greenhouse mitigation, effort generate additional income, this tends to get the attention of the management of the company and is likely to lead to further rewarding experiences.

Weather-related Stresses on Human Populations

The US experienced 42 weather-related disasters over the past 20 years that resulted in extensive damage and costs in excess of $1 billion each; 23 of these occurred in the Southeast, mostly in the form of floods and hurricanes. Projected sea-level rise could increase the risk from flooding to low-lying coastal counties from the Carolinas to Texas, which could adversely impact human health, threaten lives and cause extensive economic damage. Heat waves also take their toll; the southern drought of 1998 resulted in damages in excess of $6 billion. The same year, a combination of an unusually wet winter, dry summer and high heat led to wildfires in Florida that burned roughly 500,000 acres of land. Heat waves increase the risks of heat related illness and mortality and increase ozone production affecting primarily the elderly, the young and those who are already suffering from respiratory or other illnesses. While these are natural occurrences, climate induced changes to them can likely increase similar effects.[51] Such increases cause individuals to experience increased economic loss, increased stress from concern and worry over their physical plight and subsequent or related economic security.

Climate Change Effects Projected for Southeastern Forests

Evidence from long term monitoring indicates that climate change would likely affect individual growth rates directly by way of overall warming or change in regional moisture balance. Information presented at DAQ's April 2004 Workshop indicates an increased growth rate in trees and other vegetation will occur due to such changes.[52] Climate shifts will also likely affect tree mortality and recruitment rates by altering the frequency and intensity of stand disturbances. Results suggest that disturbance effects are stronger and quicker than growth effects. Because individual trees grow quickly and the species involved are not particularly long-lived, responses to climatic change could be relatively rapid. In natural area preserves, Chinese tallowtree and other non-native woody species (including poison ivy) may become more important if disturbances increase. In commercially managed forests, increasing disturbance rates may result in higher timber losses.

The variety of spatial and temporal influences on forest processes, coupled with uncertainties associated with climate prediction, makes difficult the assessment of the effects of changes in climate on forest dynamics at the ecosystem level. Nevertheless, research at Rice University not only identifies specific climatic effects on particular life stages or processes, but it also provides critical information for improving our understanding of the context within which these effects are likely to occur.[53]

Background on Emissions Trading Programs

In the last two decades, emissions' trading has emerged as a favorable policy mechanism to reduce air pollution. This market-based approach can often cost-effectively reduce selected air pollutants by allowing businesses to buy, trade and sell their "rights to emit" specific pollutants. If companies reduce their emissions below the limits set by government caps, they can sell their surplus reductions to companies who face higher on-site reduction costs. Businesses are thus given financial incentive to reduce emissions, under an overall umbrella of region-wide reduction totals. Such a trading market system already exists for sulfur dioxide (SO_2) and nitrogen oxides (NO_x) under the federal Clean Air Act's Acid Rain Program.[54] CO_2, being a gas, readily mixes globally. A CO_2 molecule emitted anywhere has an effect on climate everywhere. This makes CO_2 an ideal candidate for national and state emissions trading within a scale of an international market place. A national carbon market, which will require national carbon caps, provides a promise to stimulate innovation in the private sector and enable society to make reductions in more cost-effective ways.

Options exist to use the current "lead time" before the caps are established, to begin preparing for such a national and international global carbon marketplace through pilot programs and

other means. Many sectors throughout the state will then more likely have opportunities and motivation to develop greater and more incentives for reducing their greenhouse gas emissions in a more timely fashion.

The Currency of a Carbon Market: Carbon Credit$

The tradable commodity in a carbon marketplace is CO_2 equivalents (tons) or "carbon credits." These carbon credits may be earned by companies and landowners who reduce CO_2 and other greenhouse gas pollutants like methane. Credits can be earned by reducing greenhouse gas emissions directly. Under some scenarios, opportunities to earn credits may also occur through activities that indirectly reduce greenhouse gas pollution, such as renewable energy development or carbon sequestration in forests.

Supply and demand drives the marketplace. To function efficiently, a carbon market needs buyers and sellers. Currently, in North Carolina, many sectors have the potential to supply carbon credits. Possible suppliers include:

- Swine industry: for converting waste and reducing methane for fuel.
- Forestry industry: for sequestering carbon by reducing deforestation and by increasing reforestation projects for both sequestration and for renewable energy.
- Reforestation of agricultural land:
    - Planting agricultural land to trees where tobacco farmers previously grew tobacco and tobacco production is expected to be discontinued, and
    - Tree planting on agricultural lands that were former wetlands converted to agriculture prior to 1976, to create "new" wetlands for Wetland Mitigation Banking or mitigation credit.
- Agriculture industry for sequestering carbon and reducing energy use through no-till farming.
- Renewable energy industry for providing lower GHG impact energy.
- Manufacturers and utilities: for voluntarily decreasing direct emissions of CO_2 before implementation of mandated caps.
- Other Corporations (e.g., universities and business establishments, etc.): for voluntarily decreasing emissions through new energy-efficient building designs and transportation innovations.

Because North Carolina does not have a CO_2 cap, there is no current demand within the state for carbon credits. North Carolina could potentially create an economic engine for the State by implementing GHG emission reductions and establishing a carbon marketplace. Several organizations already exist that could help our State track its carbon credits and trading activity. Preparing North Carolina for the emerging carbon markets could be made possible through one of several policy options to avoid losing any such revenues to other states. Many agree that a national cap on CO_2 emissions is necessary and forthcoming.

As national carbon caps are established, North Carolina will likely need to anticipate and be prepared for the related economic opportunities. Carbon caps will undoubtedly bring a national carbon marketplace, characterized by buying and selling of carbon equivalence

credits. North Carolina should further evaluate the steps required to take advantage of such carbon market and implement evolved policies that prepare our utility, swine, forestry, agriculture and other industries, to sell carbon credits for their emissions reductions or for sequestering carbon in trees and soil. The emergence of new technologies to reduce greenhouse gas emissions from power plants, confined animal feeding operations, and other emission sources presents potential opportunities for North Carolina. By developing and evaluating ways for providing incentives for the use of such innovative technologies, we can potentially reduce our state's greenhouse gas emissions while addressing other environmental problems and even creating jobs.

In addition to capitalizing on economic opportunities, many feel that our state's top decision-makers need to be evaluating mitigation scenarios and planning how to minimize potential climate change threats (such as coastal inundation, lost agricultural revenue and human health issues). In light of the global and national pressures for action, and because of the threats climate change poses to our state, many feel that North Carolina needs to prepare its economy and its people for a carbon-constrained world.

Potential Cost Scenarios

The DAQ workshop in April 2004 (See Appendix A) provided a beginning level of cost analysis of efforts to reduce CO_2, from different viewpoints. Dr. Anne Smith's presentation[55] represented such analyses for both mercury and CO_2 measures from an industry perspective. Related discussions reflected broad reactions and variant perspectives one would expect from this type of analysis, from both environmental and industry sectors. The industry perspective is primarily that economic impacts of North Carolina attempting to address CO_2 unilaterally would be significant and negative arguing that the State needs to await federal action on CO_2, and the environmental advocates perspective is that action needs to begin now and will provide significant economic return and "reimbursements."

Some of Dr. Smith's main points were:

- CO_2 comes from coal, oil and natural gas generation, but coal emits roughly 2x more CO_2 per kwh than natural gas.
- Retrofit controls are the most costly control option with a switch from coal to gas costing about $30-50/ton C for first few %; switching from coal to renewables costing about $100/ton C for first few %; and removal of CO_2 from stack costing about $300/ton C (large reductions).
- On-system controls are expensive even for new generation. For example, she believes that building IGCC with C-sequestration would cost about $100/ton C, with large reductions possible, but likely with decades of lead-time.
- Fuel Switches, according to the analysis, would have various effects and considerations:

[55] Dr. Anne Smith, Charles Rivers Associates, Washington, D.C., ***Insights on Economic Impacts of Utility Mercury and CO_2 Controls,*** Presentation at NC Division of Air Quality Mercury and CO_2 Workshop, April 20, 2004, Raleigh, NC. (See Appendix A).

- **Coal-to-Gas**: A 20% reduction in current coal MWh would require: 1) a 50% increase in current gas generation, 2) more new gas plants to be built, 3) drive natural gas prices up (affecting other industry), and would reduce national CO_2 emissions <3%,
- **Coal-to-Renewables**: A 10% reduction in current coal MWh would require >5-fold increase in renewable capacity, to reduce national CO_2 emissions <3%, and
- **Both** would drive $/ton higher than the estimates above for "first few %" of reductions, and would require a multi-decade approach with on-system reductions costing less than $100/tonne C.

Other "off-line" changes may be more achievable she surmised: such as changes in land use practices, changes in forestry practices, energy demand-reduction projects, and projects in other countries that reduce their CO_2 baseline (a trading option). The presentation concluded that the costs would be much cheaper (<$10/ton C). Some important questions would remain: 1) Are these real reductions from baseline?, 2) Are these permanent reductions?, and 3) Will they remain cheap once there is a real demand for them? She concluded that on-system reductions would cause much higher price increases.

Dr. Smith contends that a unilateral North Carolina policy would result in the potential for power to be brought in from outside states without a carbon cap, that the cost of power and gas would rise to industry in the State, National and global emissions would not be reduced, jobs may be lost and consumers in the State will face losses in living standards. On the other hand, she indicated that as a part of a unified national carbon policy, inter-regional competitive issues would be diminished, competition would be increased with international sources, there would still be 'leaks' in emissions on an international basis, but that this State would then face impacts more similar to the U.S. wide average impacts. These concepts and information need to be debated and resolved before final recommendations are made.

Making analysis of cost impacts even more difficult will be the impact of changes in supplies, or perceived changes in supplies of energy from various sources in the world and how much it will cost. All energy prices, whether for gas, oil or coal (or other) are distinctly interrelated and fluctuate together, with some delays. Recent excursions in prices for crude oil may be temporary, but there are many who project that production of crude will peak in the next few years and begin to fall. Such changes would have a significant impact upon energy costs, but also serve to make it more difficult to determine the true effects and costs of making reductions in consumption. The graphs below in Figures III-1 and III-2 do not reflect more recent dramatic changes in cost and supply resulting to middle eastern and Russian influences on the market, but these recent events only seem to accelerate and exacerbate the issue and provide a backdrop for future discussions and conclusions.

These positions likely will undergo additional analyses prior to release of the final report, but reaching a consensus and a common resolution of the different perspectives will likely be a major effort.

CHAPTER IV REDUCTION AND SEQUESTRATION TECHNOLOGIES AND OPTIONS

Over 100 coal-fired power plants have been announced (some since cancelled) for planning and construction in the U.S. in recent years, according to Cinergy CEO Jim Rogers in a recent speech. He interjected that the current energy policy in the U.S. seems to be "find more/use more."[57] "This policy and practice has to change before these alternatives will begin to be viable to replace and reduce emissions," he summarized. Targets are needed that will provide for these advances to be put into practice and result in real and continuing reductions in the carbon limited future.

Since the release of the First Interim Report in 2003, DAQ has continued to review available literature and emerging information. In addition, DAQ hosted a workshop in April of 2004 that involved stakeholders, experts on various related topics and other interested participants. This chapter is primarily a summary and update of pertinent technical and related information on reductions in use of fossil fuels and sequestration of emissions collected from that workshop and other sources since the release of the first report.

Various methods and scenarios have been suggested to prevent emissions by reductions in carbon-fuel consumption and to capture and sequester them post-emission. These proposals cover a wide range of cost and practicality. Some are obviously too expensive or sufficiently impractical, or so energy inefficient, that they may be readily dismissed (for the time being, at least). Others may have promise and be options that may be worth further consideration, maybe in a shorter range of five to ten years. Others may require further technical development and piloting on large scale, such that they may be more likely worthy of further consideration within10 to 30 years. The purpose of this discussion is to identify the most obvious, potentially important and promising of those options and place them in the proper category for future re-evaluation. At this point, none of these options should be viewed as recommendations, but potential options for future consideration for selection of recommendations. Such final recommendations and changes may also require further coordination outside the State with other regional and national groups.[58]

Most action-initiating activity to date seems to be in the government circles. However, in 2003, the federal government and industry organizations representing companies from 12 energy-intensive economic sectors joined in a new voluntary partnership called "Climate VISION." The economic sectors include automobile manufacturers, chemical manufacturers, railroads, the oil and gas industry, the electric power industry, the mining industry, and the cement, iron and steel, aluminum, magnesium, semiconductors, and forest products industries. Joining this initiative were the U.S. Departments of Energy (DOE), Transportation (DOT), Agriculture (DOA) and the U.S. Environmental Protection Agency (EPA). Climate VISION

works with industry to identify and pursue cost-effective solutions to reduce emissions using existing technologies; develop tools to calculate and report emission intensity reductions; speed the commercial adoption of advanced technologies; and develop strategies to reduce emissions intensity in other economic sectors.

The electric power sector participates in the Climate VISION program through the Electric Power Industry Climate Initiative (EPICI) and its Power Partners program, with the DOE. The memberships of the seven organizations that comprise EPICI represent 100% of the power generators in the United States. The power sector, through EPICI, plans to finalize its work plan in the form of a Memorandum of Understanding (MOU) with DOE. The MOU will outline proposed implementation actions to reduce greenhouse gas emissions intensity by 2012. The power sector, in conjunction with DOE and other federal agencies, will implement the actions. In North Carolina, Duke Energy and Progress Energy are both participating in this program through their membership in, and participation with, the Electric Power Research Institute (EPRI).[59] Projects proposed or included to date include planting of additional forest for sequestration and other similar programs.

As discussed in the First Interim Report, the Appalachian State University Energy Center produced a report in January 2000[60] that provides an in-depth analysis by sector of their recommendations for a sensible GHG reduction strategy. This document has some parallels to that report and draws upon it to some extent without reproducing the estimates and calculations included in that report. That same Center assisted in a major portion of the tasks associated with development of the State Energy Plan (SEP) as discussed further on the following pages and in Appendix D to this document. The Figure IV-1 below, extracted from that report, gives a good refresher or reference point from which to review the importance of the various sectors toward realizing a potential solution.

Energy Efficiency : Use Less - The State Energy Plan

The most obvious way to reduce CO_2 emissions is to burn less carbon-based fuels. This is essentially one of the major goals of the State Energy Plan. For most practical purposes, the reduction of CO_2 and reductions of energy usage are synonymous. Thus, the State Energy Plan (SEP) is closely related to the development and implementation of action plans for the reductions of GHG in North Carolina. Efforts and actions to reduce energy consumption will translate into reductions in GHG emissions, particularly CO_2.

The First Interim Report discussed the SEP in limited detail. The SEP was approved in June of 2003. The State Energy Office (SEO) and other departments are now working on strategies for implementing that plan. For example, the SEP envisions a North Carolina Climate Action registry as one of its products.[61] This is in relative harmony with the implications of programs to reduce greenhouse gases. Some additional tracking mechanisms for the results and progress of reducing emissions through the implementation of the SEP, for example, may be necessary to allow tracking of progress for the overall effort. Thus, the two programs are closely linked and must track closely together. A copy of the NC's SEP may be obtained from the SEO, or may be downloaded from their web site.[62] The SEP provides most of the information discussed in this section of the report.

The SEP indicates that CO_2 emissions will likely continue to increase into the near future and the only viable options currently available for reducing these emissions are increasing efficiency and switching to alternative sources of energy generation, such as nuclear, hydropower, solar, wind and biomass. Although combustion of biomass produces one molecule of CO_2 per molecule of carbon in the material, just as fossil fuels do, the biomass is "re-used" carbon that was not derived from ancient deposits or previously sequestered emissions, and thus does not have the same net impact upon the environment as do the "new" fossil fuels. Large conversion may be unrealistic without wholesale switching to more expensive natural gas combustion with less certainty in supply.

The Secretary (or designated representative) of the Department of Environment and Natural Resources (DENR), represents DENR on the Energy Policy Council (EPC). This facilitates coordination and implementation of the SEP and its integration with parallel actions and plans to reduce GHG. In 2003, the EPC approved 93 measures that meet the plan's objectives. These measures, in the form of policy and program recommendations, primarily address the following sectors and issues in the state:

- Energy, Economics and the Environment
- Fossil and Nuclear Fuels
- Electric Utilities and Energy Use
- Alternative Fuels from Biomass
- Alternative Energy Sources
- Energy Use in the Public Sector
- Energy Use in the Residential Sector

---

[61] Larry Shirley, Director, State Energy Office, *Development, Components and Status of the NC State Energy Plan*, Presentation at NC DAQ Mercury and CO_2 workshop, Raleigh, NC, April 19, 2004. (See Appendix A).

[62] *State Energy Plan*, http://www.energync.net/State%20Energy%20Plan%202003.pdf .

- Energy Use in the Commercial Sector
- Energy Use in the Residential Sector
- Energy Use in the Transportation Sector
- Funding for Energy Policies and Programs

Appendix D contains a more extensive listing of SEP recommendations and lists the 15 key legislative, regulatory, and administrative policies the EPC determined would require action in 2003 and 2004. Some of the items discussed in more detail below also relate to elements in that plan. Basic elements of the plan are addressed below.

Programs to Directly Increase Energy Efficiency at Generation Units

Most of the existing coal-fired boilers in North Carolina, and elsewhere, were built many years ago, in the general era between 1950 and 1980, with an expected lifetime of 30 to 50 years. Thus, the population of boilers is aging, many already beyond their originally expected useful life. In the meanwhile, a number of design and technology advances have been made that could potentially make improvements in efficiency if applied to existing facilities. These improvements may only be on the order of a percent or a few percent, but are significant in the economics of running a large power generation unit constantly for several years. The increases in design efficiency generally allow more production of electricity with less fuel and with less emissions of nitrogen oxides, which leaves less to be removed by other means. Due to the costs and the complexity of the regulations (e.g., State/federal new source review and prevention of significant deterioration regulations) many improvements and refinements that might have made have been discouraged or confused in complications. Some efficiency improvements on generation units can be made, but may require consideration of such projects under EPA's new source review (NSR) rules.

In the December 31, 2002 proposed rule on Routine Maintenance, Repair, and Replacement (67 FR 80290), EPA indicated that, "NSR should not impede industry in making energy and process efficiency improvements which, on balance, will be beneficial both economically and environmentally" (57 FR 80301). The State is currently reviewing related rules and policies to determine if any changes need to be made to North Carolina rules and whether there may be any additional latitude resulting to encourage (or not discourage) such projects.

State Agencies, Local Governments, Schools & NPOs

The State's cost of energy and fuel (excluding gasoline) in 2002 was $179 million.[63] The largest share of the State's energy expenditures was for electricity, which was 65 percent of the State's total energy costs. The university system is the largest consumer of energy in North Carolina's state government. Over half (53 percent) of the State government's energy expenditures occur at the universities. New education construction bonds passed in 2000 may further increase energy consumption by the university system if offsetting

[63] *State Energy Plan*, *State Energy Plan*, North Carolina State Energy Policy Council/State Energy Office, http://www.energync.net/State%20Energy%20Plan%202003.pdf., June 2003.

energy efficiency measures are not incorporated into these projects and retrofitted to existing structures.

The North Carolina League of Municipalities, North Carolina Association of County Commissioners, and North Carolina Association of School Boards have formed a collaborative association named LoGESO (Local Government Energy Savings Organization). In 1999 and 2000, LoGESO conducted an assessment focused on what they might do to reduce energy expenditures. They evaluated steps that constituents might take to conserve energy and improve efficiency. The study found fewer than 25 percent of potential energy efficiency expectations had been realized in the sites focused on during the study. This was due, in part, because of the small size of many energy efficiency projects. They did not attract competitive bids from established firms, they concluded, due to the high costs of assembling bids. In addition, few local jurisdictions tracked and reported energy use and expenditures. Based upon the consultant's experience elsewhere, North Carolina local governments could experience a 5-10 percent reduction in purchased energy through an aggressive energy reduction program. This would result in an estimated $50 million in savings over a five-year period.

The cost of energy represents a significant drain on State and local resources. Educational facilities also stimulate fuel use for transport of children to and from schools via both personal vehicles and school buses. The total cost of student transportation is a substantial portion of the total cost of energy for education. Increased adoption of walking and biking, as well as increased bus use by those commuting by private vehicles could save substantially on total energy consumption, and thus related emissions. [64]

Commercial/Industrial

The commercial sector has a high potential for improving efficiency in both existing and new buildings. Insuring energy reliability, promoting wise land use and improving environmental quality are directly related to energy efficient construction codes and techniques. Efficiency strategies for commercial buildings include building energy efficiency, lighting efficiency and increased use of natural daylight, heating and cooling system efficiency, alternative energy options and hot water efficiency.

North Carolina's industrial sector uses about 28 percent of the total energy used in the state (the highest in the state). Energy saving improvements for industry are typically grouped into four primary categories:

- General energy-saving technologies applicable to all manufacturing sectors, such as high-efficiency lighting and computer control of air conditioning.
- Industry-specific energy-saving technologies, such as recovery of "waste" heat.
- Energy management activities, such as energy audits, load control and full-time energy managers.
- Other innovative approaches, such as changing processes or developing new approaches for industrial development.

---

[64] *State Energy Plan*, *State Energy Plan*, North Carolina State Energy Policy Council/State Energy Office, http://www.energync.net/State%20Energy%20Plan%2003.pdf ., June 2003.

A study conducted by the national energy laboratories, including Oak Ridge, Lawrence-Berkeley and the National Renewable Energy Lab, concluded that nationwide energy savings of 7.4 percent in the industrial sector could be achieved by the year 2020 by implementing moderate energy saving programs. With a more aggressive approach, savings of 16.5 percent by year 2020 was determined to be possible. These savings excluded the effects of increased combined heat and power (CHP), or co-generation. With moderate implementation of CHP, the national labs' report estimated that national energy savings of 1.1 percent could be achieved by 2020. Under such an aggressive program, an estimated 5.8 percent would be saved. The potential decreases in energy consumption from the policies recommended for the industrial sector of North Carolina total about 8.5 percent in existing industrial facilities and 12 percent in new facilities.

Residential

In 2000, residences in North Carolina accounted for 23 percent of the total energy consumption in the state. Because this sector concerns virtually every citizen of the state directly, energy use in residences remains key for energy efficiency. The residential sector provides tremendous opportunity for reducing energy use. Fortunately, many energy efficiency measures are cost-effective and provide additional advantages to the owner, such as improved comfort and increased home durability and benefits to the state, such as reduced air emissions, lower fuel imports and the economic benefits of direct expenditures for energy-saving products. New homes with greater energy efficiency usually cost just marginally more than comparable less efficient homes. Efficient homes help reduce the costs of home ownership, because the annual energy savings generally exceed the additional annual mortgage costs.[65]

[65] *State Energy Plan*, North Carolina State Energy Policy Council/State Energy Office, http://www.energync.net/State%20Energy%20Plan%202003.pdf., June 2003.

Renewable Energy (Substitution for Fossil Fuels – Also Addressed in SEP)

Although substitution of renewable energy for fossil fuel energy is somewhat inherent in the SEP, it is identified here separately because of its importance in many discussions on the CO_2 topic. There are several promising ways to utilize renewable energy to potentially replace or substitute for the combustion of fossil fuels. One must also keep in mind that some sectors of renewable energy, such as combustion of biomass will also release CO_2 emissions and though they substitute for fossil fuels, this release of GHG must be taken into account in evaluations. Several of the renewable energy sources generate electric current without any combustion or generation of CO_2 or other GHG.

NC GreenPower, included in the SEP, and now in an active process of recruiting members or participants, is an existing (but new) program in North Carolina that provides customers with the option to purchase units of "green" power generated with renewable or other means of substitution for electricity that would be otherwise be generated from coal-fired units. The more participation there is from the customers, the greater the environmental benefits, including reductions in "new" CO_2 from fossil fuels. This program is unique to North Carolina, with all three utilities included, as several co-ops. The program allows most citizens of the state the opportunity to participate (A "reasonable" premium is charged for the option to actually purchase the green power units with these funds being used directly to offset extra costs of procuring that power).

In the United States, we have grown accustomed to very dependable power. When the switch is flipped, it is rare for the lights not to come on. However, one of the potential downsides of renewable energy may be the loss of some of this reliability, according to the "naysayers." A substantial quantity of new infrastructure dispersed among many locations would be required to provide the levels of "replacement" energy needed, and designs of those systems will need to keep reliability as a strong consideration. Some of this proposed capacity would not always be available when needed, which would likely require other generation capacity to be available for back-up when there are periods of rain (solar), low wind, disruptions in the supply of biofuel, etc.. Thus, such plans and changes would need to consider these options and situations holistically so that the system is adequate to cover all situations, at all times, whether by providing excess capacity of other renewable generation or by more conventional means. If the latter, some economic subsidy might be necessary to guarantee that this capacity, otherwise idle, would be available when called upon.

Solar:

The sun's energy can be used in four primary ways:

- solar thermal,
- passive solar heating and cooling,
- day-lighting and
- Photovoltaic.

Solar thermal collectors function relatively well in North Carolina's diffused sunlight. Solar thermal includes using solar energy for heating or cooling of interior spaces and water heating. In addition, solar energy is used for cooling and refrigeration. When concentrated with lenses or mirrors, sunlight can generate boiling water which is used directly or to drive various types of engines. This steam can be used to run steam turbines to produce electricity, much like in coal-fired power plant.

Passive solar includes orienting windows toward the south, and using concrete and other heavy building materials for thermal storage and shading strategies that avoid summer overheating. The SEP reports that "Passive solar buildings can have comparable costs as similar, non-solar structures and yet save significantly on heating and cooling costs while providing improved comport and quality of light. The main constraints are lack of awareness and consumer demand along with inadequate training and interest among residential and commercial designs, builders an developers."

Day-lighting is the practice of paying special attention to the use of natural lighting in the design stages of buildings and can provide an energy and cost savings in buildings if properly conceived and implemented.

Photovoltaic devices provide a newer frontier in capturing and using solar energy. They do not capture sunlight's heat energy directly, but rather use solar radiation directly to stimulate a flow of electrons, thus generating electricity. Photovoltaic energy is cost effective in some remote locations, but further research and technical advances are needed before the cost per peak watt of electricity is economic in typical situations. Some new technologies are dual functioning to make them more cost effective. For example, a roof system could be made of photovoltaic material thus providing electricity and roof protection for a residence.

One of the big advantages of solar energy systems is that they are most effective in producing energy in the summer months, the season with the peak electric utility demand in North Carolina. The very nature of solar energy systems thus cut electrical demand on the electrical grid during peak demand periods.

Wind/Substitution

Wind power generation is the fastest growing electricity generation technology used in the world.[66] Of the 10 wind classes that exist, determined by average annual wind velocities, the continental United States only has sites with the less intensive six classes. Class 5 and 6 sites are abundant in North Carolina's western mountains; with class three and class four sites being located in the mountains and along the eastern coast. Many of the mountain sites could likely generate electricity in the range of $0.03 to $0.04 per kWh - competitive with new coal and natural gas generation. According to the Energy Efficiency and Renewable Energy Network, North Carolina has the capacity to produce 8

[66] Dr. Dennis Scanlin, Appalachian State University,, *Wind Energy in North Carolina*, DAQ Mercury/CO_2 Workshop, Raleigh, NC, April 21, 2004 (See Appendix A)

million MWh, or about 7 percent of current electricity consumption in the State. This would come from using wind technology in Class 3 and higher sites only.

Two tax programs encourage wind energy generation. The federal Production Tax Credit (PTC) provides $0.018 per kWh of wind energy generated, and North Carolina's Renewable Energy tax credit (35 percent, with a maximum of $250,000). In order to compensate for existing development, environmentally sensitive areas, and other land-use conflicts, this estimate excludes 50 percent of total forests, 30 percent of total farmland, and 10 percent of total rangelands. The federal tax credit is in jeopardy of expiration which would be a significant blow to this program and the future of investments in wind energy.

Cost to site wind machines in areas with the greatest wind resources; namely the high ridges in Western North Carolina, is the single largest barrier to wind technology in North Carolina. The Mountain Ridge Protection Act of 1983, also know as the Ridge Law, was designed to prohibit the construction of unsightly structures taller than 35 feet on North Carolina ridges above 3,000 feet in elevation. Although exclusions exist for telecommunications towers, electrical *transmission* facilities, structures of a "relatively slender" nature, "minor" vertical protrusions, and even "windmills," the North Carolina Attorney General stated that electrical *generation* equipment is in violation of the Ridge Law. If upheld, this interpretation effectively prohibits development of many sites with the best wind resources in North Carolina.

Hydroelectric/Substitution

Hydropower currently represents the primary renewable energy supply for utilities in North Carolina. In 1999, hydroelectric plants supplied over 3.5 million MWh of electricity or about 3.5 percent of total state electricity sales. Hydroelectric generation typically requires less initial capital than coal and nuclear facilities, but more than natural gas, while typically providing the most economical source of electricity in terms of actual costs of generation. With a price under $0.025 per kWh, the total cost of hydroelectric generation is the cheapest source of electricity currently available for North Carolina.

The Idaho National Engineering and Environmental Laboratory, under contract with the DOE, assessed North Carolina's undeveloped hydroelectric generation potential. The study found 93 sites in North Carolina with approximately 508 MW of undeveloped generation capacity that might be used to generate electricity. The greatest capacity of any one site was 76 MW but over three quarters of the sites were estimated to be capable of providing less than five MW. According to the Energy Efficiency and Renewable Energy Network, North Carolina possesses roughly 8 million MWh of total new hydroelectric generation potential, which would meet approximately 7 percent of all generation in North Carolina.

A significant barrier to additional hydroelectric power for North Carolina is the drought experienced in recent years and the expiration of avoided cost contracts between electric utilities and owners of hydropower facilities. Hydropower's environmental impact on the ecology of the operation site has also been a significant deterrent to new development. A

shift away from large-scale projects to less intrusive low-head, small and micro-hydro projects has some responsibility. Rapidly growing demand for water for irrigation, industrial processes, cooling water, fish and wildlife considerations, and other human needs pose further limits to expanding hydroelectric development. All these factors will likely be considered when and if licensing or re-licensing events arise.

Biomass Burning/Substitution

Biomass is a carbon-based fuel, often derived from fast growing trees, or bushes, that can be used to fuel utility and other boilers. Though burning of biomass generates CO_2, it substitutes carbon already in atmospheric and biome circulation, for fossil fuels, thus lessening the net impact of "new carbon" on the overall environmental system. Agricultural and waste management sectors provide potential sources of energy for both electrical generation and other direct uses as fuels. Additionally, recent proposals and programs for fire hazard reduction have increased the interest and economics of using small diameter (low economic value) trees, bushes and shrubs for replacement of fossil fuels in electric generation. Efforts to further evaluate and extend such efforts in North Carolina are underway at NCSU and in the DENR Department of Forest Resources.

DOE estimates that 15.8 billion kWh of electricity could be generated from renewable biomass fuels each year in North Carolina. This is enough electricity to potentially supply about 39 percent of the residential electricity demand in the state. Of these sources, 80 percent of the potential biomass fuels would be from wood waste from logging, industrial, yard waste, furniture manufacture and construction. While more biomass as fuel offers a partial replacement for fossil fuels such as petroleum or coal, combustion of the biomass still creates climate change emissions and may provide additional control issues for other pollutants, such as NOx and particulate matter.

The largest potential supply of woody biomass for energy is standing timber or "stumpage." Much of North Carolina's 18.3 million acres of forestland is occupied by low-value trees not well suited for traditional wood markets. Twelve million of these acres are considered as having high potential for wildfire, a danger not only to the forests, but also to the surrounding communities, especially North Carolina's rapidly expanding urban-rural interface. On December 3, 2003, President Bush signed into law the Healthy Forests Restoration Act. This act targets forests presenting wildfire danger and calls for reductions in low-value standing fuels, restoration of healthy forests, and development of woody biomass energy. Development of a woody biomass energy market in North Carolina can help reduce fire danger while improving forest health.

Wood chips have not worked well as a fuel for co-firing with coal in utility boilers except in gasification applications. However, woody biomass has been used successfully for distributed generation across the U.S.,[67] and to the extent this occurs, current and future load requirements of fossil-fired power plants are reduced.

---

[67] Dennis Hazel, NC State University, Forestry Department, *Written Comments on Draft 2nd Interim Report*, August 9, 2004.

Use of biomass has secondary advantages of using damaged and depleted soils and aiding in their restoration. There is a benefit of sequestering more CO_2 (albeit somewhat temporarily) in soils in the process of adding organic matter to these soils. Since the Southeast has a long warm season and substantial water, it is well suited to growing biomass "crops.

Biofuels, including ethanol, biodiesel and mixtures, are made from various agricultural crops and residues. However, the resulting fuels are usually interchangeable with conventional fossil fuels in regular vehicles without modifications, especially in diesels. Ten tons of biomass can yield ~1000 gallons of biofuel, resulting in emission reduction from their use in vehicles due to the clean burning nature. Particularly, there is little or no sulfur emitted from these fuels, in contrast to petroleum-based fuels.

North Carolina has abundant biomass, such as landfill gas, mill residues, animal waste, forest residues, energy crops and urban wood. These fuels have a potential to supply up to ~20 percent of North Carolina's electric needs. Thus, high growth is predicted in this economic sector over the next decade. These fuel sources have the economic potential to create more local jobs, particularly in rural areas than many other types of projects. In addition, existing infrastructure (yards, trucks, rail sidings, etc.) uniquely positions the North Carolina wood industry to procure and deliver bulky biomass crops in a timely and efficient manner.

Biofuel conversion facilities are currently planned for construction in North Carolina.[68] However, EPA has specifically listed fuel switches from coal to natural gas, and from coal to wood, as pollution control projects that would be presumptively environmentally beneficial in the Final Rules on Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NSR) issued on December 31, 2002 (67 FR 80186). DAQ is currently evaluating rule options and these will be implemented whenever they are final rules.

NC GreenPower, discussed earlier, provides an example of the use of renewable fuels to replace fossil. A recent summary of the NC GreenPower program appeared in the DENR's newsletter.[69] Survey and practice have indicated that the public is willing to invest additional premiums on their electric bills to insure the use of additional renewable energy, but the program is still in its early stages and will provide further indication of this factor as time passes and experiences accumulate.

There are additional issues that arise from considering biomass sequestration as a potential partial solution to the atmospheric carbon burden. There is a potential for biomass and carbon sequestration to work at cross purposes. Forestland planted for the specific purpose of carbon sequestration cannot be used as a source of biomass and then counted as sequestration. To do so would negate the benefit of the sequestration, and incidentally, any carbon credits earned.

Capture and Use of Underutilized Energy Sources/Substitution

Energy capture includes such activities as recovery of methane from landfills and from animal manure. Confined Animal Feeding Operations (CAFO's) are of particular importance in North Carolina. The State is nationally number two in ranking for hog production and has a swine population of about ten million (Iowa is number one with approximately fourteen million) out of a national total of approximately sixty million. Poultry operations, particularly chickens and turkeys are also important in the State, with dairy and beef cattle being important, but contributing to the waste "resources" with a much lesser quantity. If one does look at these wastes as a resource awaiting development, the potential impact becomes significant.

Research has been underway in this area for several years in North Carolina at the North Carolina Animal and Poultry Waste Management Research Center on the North Carolina State University (NCSU) campus and at several other agricultural campuses throughout the country. They have been attempting to develop better means of disposal of animal waste, many targeting recovery of resource value. In 2000, Smithfield Foods and the North Carolina Attorney General's Office entered into agreements to fund and study "promising new technologies" with expectation that these would provide solutions to the ammonia and odor problems in particular, and to waste disposal problems in general.

Results of this program have been recently unveiled. The reports are just recently available, but some of the promising technologies studied included methods and processes to turn the carbon in the waste into fuels for distribution as an energy source. This program will continue to pursue many of the technologies and make them more economically viable, but the conversion options, in particular, may hold promise for supplementing the fuel supply at no large expense on the CO_2 budget, providing another source of carbon fuel that does not depend on fossil fuels. At the DAQ Mercury and CO_2 workshop, Kurt Creamer, P.E., one of the researchers from NCSU, who has been working on this project with Dr. Mike Williams, Director of the Smithfield Agreement Project, discussed these efforts.[70] Reports from the research currently being released will be available soon and the studies will likely result in several papers and other technical documents over the next several months and few years.

Recovery of methane from other decomposing "bio-materials" such as found in landfills and wastewater treatment facilities, has been increasing and provides additional potential for added use. Several operations in North Carolina utilize these operations to "mine" methane mixtures from the natural anaerobic decomposition and utilize them in boilers and other combustion equipment with the eventual production of steam and electricity. In fact, EPA first research on this potential was first conducted on landfills in North Carolina and the technology proven as economically viable. Electricity may be used by the generating entity or sold to a neighbor (if legally allowed in the circumstance). Steam may be used directly or sold for process heat, agricultural production (e.g. greenhouse crops) and other uses.

[70] Kurt Creamer, *NC Animal Waste as a Potential Resource for Reducing CO2 and Methane Emissions*, Presentation at DAQ Workshop, Raleigh, NC , April 21, 2004 (See Appendix A), www.cals.ncsu.edu/waste_mgt/.

One factor that may need additional discussion and actions within the Legislature related to these type operations is the legal constraints and implications regarding the sale of electricity to the grid (net metering) or to a neighboring industrial, commercial or residential area. Laws pertaining to their being a regulated monopoly protect the electric utilities and these laws may require evaluation for change. Some energy developments such as the production of electricity from animal waste, land fills and other operations that may need to sell electricity to their potential customers may raise issues regarding the legalities and limits of such operations with regard to these same laws and regulations. They may not constitute impenetrable barriers, but further evaluation and possible legislative actions will likely be needed before it is possible to fully adapt some of these energy sources.

Post-Emission Capture and Sequestration

This section is primarily to address the capture and sequestration of CO_2 after already emitted by the combustion of carbon fuels by biological or technology and hardware.

Agricultural and Forest Sequestration

Growth of plants and other organisms that utilize CO_2 in their natural metabolic processes, remove CO_2 from the atmosphere. If this were not the case, the atmospheric concentrations would be much higher. As discussed by Dr. Schlesinger of Duke University in his presentation at the April 2004 DAQ workshop,[71] forests increase their growth when exposed, or immersed, in elevated levels of CO_2. Thus, the growth of any forest or crop is likely to increase uptake, just "because it is there." However, it is evident that this increase in uptake is not sufficient to offset the rate of increase of release of CO_2 that is encountered globally today. Increases in biomass and organic matter in all U.S. forests in the past 40 years have only offset ¼ of the national emissions during that period.[72] However, these emissions can be offset to a significant degree[73]. Therefore, many efforts and proposals have been advanced to increase the sequestering efficiency and quantity of crops and forests that can uptake and provide "sequester-able" carbon in the form of wood for paper, building materials or fuel. One must be careful to maintain a separate accounting for carbon sequestered that will again be burned or otherwise oxidized and those that will likely remain in the unburned state for decades or even centuries and effectively remove that carbon from circulation on a permanent basis.

One of the most significant threats of climate change to North Carolina is the loss of the State's rich biodiversity. Policies to sequester, decrease or offset CO_2 emissions must be evaluated with consideration for biodiversity protection consistent with other environmental programs and policies. Storage and sequestration of carbon in forests can

potentially provide North Carolina an additional productive mechanism to sequester CO_2. Existing North Carolina forests currently store roughly 416 million tons of aboveground carbon. Planting new forests could sequester substantial additional carbon.[74,75] Programs for added permanent carbon sequestration through forestry thus provide a serious option to mitigate CO_2 emissions from power plants and other sources.

Carbon Storage Trends for North Carolina's Forests:

As North Carolina's forests diminish, so does their use as long-term storage of carbon. North Carolina lost more than 1 million acres of forests over the last 12 years, largely due to urban sprawl. North Carolina's forests now occupy 18.3 million acres, even less than in the 1930s, following an era of agricultural conversion.[76] Many forest communities have been especially hard hit, most notably the state's natural pine. Longleaf pine declined 30% since 1990, [77] and shortleaf pine declined by 38% in the same time period.[78] This trend of forestland loss is projected to continue for at least the next four decades[79]. Steady decline in the state's forests means a decrease in the amount of CO_2 stored. In fact, the loss of forestland over the past decade resulted in the loss of roughly 17 million tons of aboveground carbon.

Older forests store more carbon than younger forests but North Carolina's forests are getting younger. Since 1990, forests younger than ten years old increased by 15% and forests between 11 and 20 years old increased by 35%.[80, 81] Younger forests provide less suitable habitat for wildlife and have much less capacity for carbon storage than older age classes. Forests harvest rates have overtaken growth rates. Timber harvests have increased 30% since 1990, following another large jump in harvest rates during the late 1980s. Of harvested acres, 76% were clear-cut, which increases runoff, sedimentation and water quality concerns if not properly managed and impact the ability of forests to retain sequestered carbon.

Complexity of Carbon Sequestration

When considering carbon sequestration, the total amount of carbon sequestered should be the greatest priority and measure of effectiveness. Fast-growing trees accumulate carbon more quickly than slower growing trees, but this only accounts for a portion of the carbon that may be stored in a forest. When considering carbon sequestration comprehensively, it is important to also account for forest types, soils, management activities and stand age. Many generation and sequestration activities are occurring simultaneously in this complex situation, as illustrated in Figure IV-1. All the variables in this figure can have impact on the effective sequestration process.

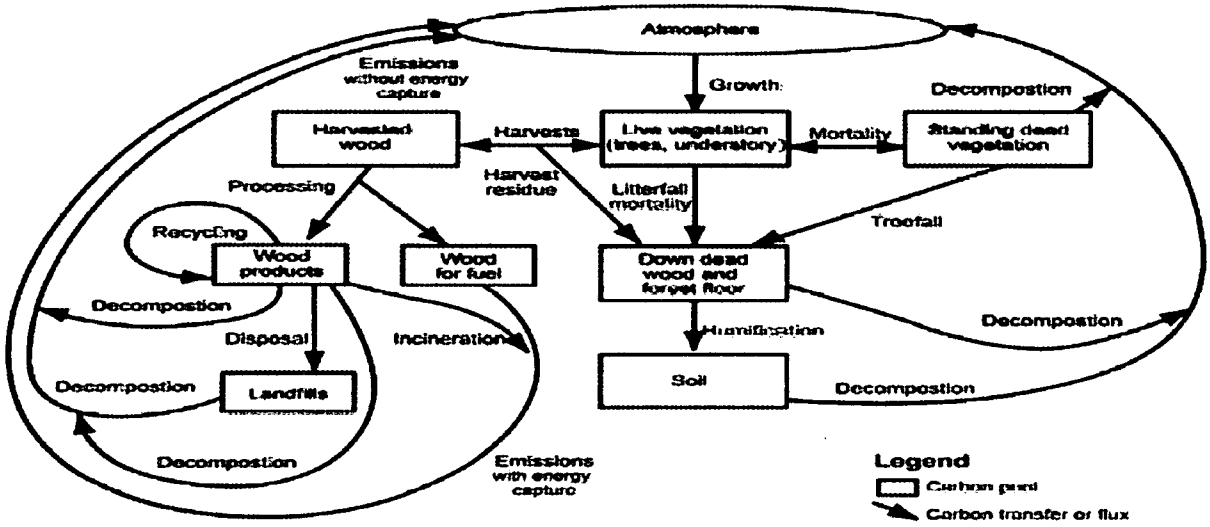
Figure IV-1
Summary diagram of forest carbon stocks and carbon transfer among stocks



Source: Adapted from USEPA (2003a), and Heath and others (2003)

In general, southern hardwood forests store more carbon than pine forests. Southern forests average 25 tons per acre of above ground carbon, but this figure varies widely by forest type. Southern pines (loblolly, longleaf, slash, etc) average 14-19 tons per acre of aboveground carbon. By comparison, bottomland hardwood forests and Appalachian hardwoods average 32 tons per acre of stored carbon.[82, 83] Loblolly pine can sequester 3.2 tons CO_2 annually compared to rates of 2.3 – 3.4 tons CO_2 annually for hardwood forests on old agricultural lands.

Forest soils account for some 50 – 60% of the total carbon in temperate forests.[84] Converting intensively managed agricultural fields to forests would be expected to begin the process of rebuilding soil carbon pools. Several studies have documented the CO_2 sequestration potential of forests in the Southeastern US. One study[85] reported that a 35 year-old loblolly pine stand had removed 345 tons per acre of CO_2 as plant carbon and 176 tons per acre as soil carbon. Another study[86] reported average annual sequestration rates of between 1.7 and 2.2 tons per acre of carbon over the first 15 years and as many as 110 metric tons total in 90 years in many parts of the Southeast.

Forest management affects both the growth rate of woody biomass and the soil carbon (as described above). When forests are managed for "maximum financial yield, they will

Sampson and D. Hair, ed.) **American Forests**, Washington, D.C.

rarely contain more than approximately one-third of the carbon stored in a forest grown to maximum biomass."[87] Similarly, forests that are publicly owned have the highest rates of above ground storage per acre, while more intensively managed forest industry lands have the lowest carbon storage rates. Family-owned forests fall between these two groups.[88] Harvesting forests releases carbon into the atmosphere for many years. In fact, after a forest stand is harvested, the land serves as a carbon source for the next 15 or so years.[89] In addition, some 53% of the carbon in harvested wood is lost through emissions and energy use.[90] Wood that is used in permanent construction provides the net sequestration, creating positive entries in the carbon balance ledger. Sequestered carbon that is then burned does not add to the net sequestration.

Recent Developments in Georgia and California

In **Georgia,** a new law[91] has established a registry for offsetting reductions in greenhouse gases obtained by carbon sequestration relating to forest resources and other plant life. This law provides for development of purposes, function, procedures, protocols, etc. for a voluntary reporting on standardized forms and software, and other requirements, to stimulate and track sequestered carbon emissions from forests and agricultural activities in the state. This new law is rather unique, but reflective of the role sequestration may be able to play in lowering net emissions of GHG to the atmosphere.

The Georgia law is specifically directed at direct human-induced land use change or forestry activities, additional human-induced activities related to removal by sinks in land use change and forestry categories, additional human-induced activities related to removal by sinks in agricultural soils, additional human-induced activities related to removal by sinks in products in use from harvested timber or agricultural crops and other human-induced activities related to removals by sinks. This legislation may be of interest for future directions in other states, but being voluntary, it is not ideally formulated to provide a significant role in a comprehensive program for reductions of GHG in the atmosphere.

California's Climate Action Registry (SB812),[92] passed Fall 2002, allows landowners to register increases in their forests' carbon stocks derived from stewardship forestry and conservation. SB 812 is the third in a series of significant state legislative initiatives to combat global warming, and follows on the heels of AB 1493, which calls for the regulation of automobile CO_2 emissions. SB 812 ensures that including the forestry sector in registries, and crediting forest activities to reduce emissions, will make a significant difference in carbon dioxide levels. For carbon stocks to qualify for the California Registry, the bill requires that:

- Forest practices must exceed legal and regulatory requirements, thus preventing carbon dioxide emissions and achieving reductions of carbon dioxide in the atmosphere beyond those that would take place otherwise.

- Forest carbon benefits must be permanent, making a permanent difference for global warming and conservation.
- Forest practices must promote and maintain native forests, while avoiding the environmental harm that could result from the planting of non-native species.

Creating an Effective Carbon Storage and Sequestration Program

Carbon sequestration has gained favor as a viable option for reducing CO_2 levels in the atmosphere. Currently these sinks handle about 15 percent of the manmade emissions.[93] The USDA currently has a global change research budget of about $71 million per year which is among other things, evaluating effectiveness of various agricultural and forest potentials.

A carbon sequestration program must have an accurate system of measuring and recording carbon stocks if it is to ensure long-term atmospheric benefits.[94].. Carbon can be stored over very long time horizons, but land use changes can rapidly reverse gains. An effective carbon sequestration and storage program must include mechanisms to ensure that users of stored carbon are fully responsible and liable for replacing carbon that is lost in the future. Creating such mechanisms will likely foster innovative solutions to manage risks, such as carbon insurance.

This discussion of carbon sequestration and storage raises additional issues for the use of biomass as a potential (partial) solution to reduce the atmospheric carbon burden. Policy considerations for the use of biomass as a fuel are similar to those for permanent sequestration. The potential for biomass fuels and carbon sequestration to work at cross-purposes must be recognized and incorporated into such an effort. Forestland planted for the specific purpose of permanent carbon sequestration should not be turned into biomass for fuels. To do so negates the benefits and any carbon credits earned.

A forest carbon sequestration program must create additional reductions in greenhouse gases to be effective. These reductions must go beyond those reductions that would have occurred without the carbon sequestration program. This concerns both on-the-ground practices and utilization of harvested wood products. Only carbon that would otherwise not be sequestered should be credited. An agricultural field planted to trees represents the simplest accounting situation. How to credit existing forests or forest products that would have been created anyway presents a greater challenge. Current planning should consider sequestration as an integral factor in the overall plan for GHG reductions.

Carbon sequestration provides an excellent yet challenging opportunity for North Carolina to address sequestration of some of the atmospheric CO_2. The most ideal scenario might be the development of policies that provide the greatest opportunities for reducing emissions and protecting other conservation goals such as biodiversity. Developing policies consistent with existing policies and programs to protect the State's

[94] Adapted from Environmental Defense. "A Bridge to Climate Protection: Slowing Global Warming by Marketing Carbon Stored in Farms and Forests," 2003.

diverse natural resources will ensure the greatest benefits, and will be an option to consider in addressing this issue further.

End-of-Pipe Hardware/Technologies

Several methods to reduce emissions directly from the stacks of fossil fueled power plants (primarily coal) have been proposed and are being researched by the DOE. Though some of these may be useful in the future, they are still in the development and proving stages and not ready for practical and "off the shelf" application. Some of these are discussed below for completeness and planning purposes and complete recommendation options. The DOE Global Climate Change Initiatives[95] stated goal is to achieve a 90 percent CO_2 capture with less than a 10 percent increase in cost of energy services (net of any value-added benefits, e.g., CO_2 credit trading, etc.). This can be adopted as "rule of thumb" criteria for assessing the practicality of various technologies available, or under development. Further discussion on individual technologies is presented below. The rather extended discussion of approaches and research is not intended to imply that many, or any, of these technologies are likely to be available for "off shelf" use in any near term period.

CO_2 Capture Options

A second approach to reduction of emissions of CO_2 into the atmosphere from coal fired boilers and other large facilities is by capturing them by some means and converting the CO_2 chemically or physically into a form or substance that can be stored indefinitely. This may be through "end of pipe" hardware approaches or by other means. At the DAQ workshop in April of 2004, Kevin Johnson provided an excellent overview[96] of means that might be feasible to capture the CO_2 that has already been formed (i.e. exhaust from a smokestack) and permanently sequester it. The capture technologies being most enthusiastically evaluated or developed fall into basic categories described below.

Conventional Amine Absorption

Conventional amine absorption is the only technique used commercially, to date, to capture CO_2 from flue gas. Essentially, a chemical compound (amine) is injected into a flue, by way of a variation of a scrubber-like device that maximizes chemical contact and reaction. This device captures the compounds in a form that is sufficiently stable to be handled without special precautions, such as specific limits on temperature, pressure, etc. The amine degrades via oxidation and reaction with SO_2 and other flue gas constituents to lessen its performance over time. Lower amine concentration results in larger equipment, higher solvent circulation rates, and increased energy requirements for CO_2 regeneration from the rich amine stream. Only a few small plants (<1000 tpd CO_2 removal, or about 50 - 100 MW) are in commercial operation. Currently, this approach of 'conventional' amine absorption/stripping is estimated to increase electricity costs by over 50 percent, and consume 30 percent, or more, of plant's

---

[95] Bob Kane, USDOE, Climate Challenge Program, ***The Administration's Global Climate Change Initiative And Enhanced Opportunities for Carbon Sequestration On Minded Lands***, USDOE, , http://www.mercc.osmre.gov/PDF/Forums/MarketBasedReforest/1-1.pdf.

[96] Kevin Johnson, URS Corp, ***Some Projected Add-On Control Options for CO_2 Reductions at a Coal-Fired Generating Unit,*** DAQ Mercury and CO_2 Workshop, Raleigh, NC, April 21, 2004 (See Appendix A).

output.[97] Though technically feasible, this sort of penalty does not appear to offer a practical solution at this time.*Advanced Amine Absorption*

Advanced amine absorption uses proprietary oxidation inhibitors and other additives with specially designed membranes, custom solvent and amine formulations with a similar basic approach. Various commercial vendors have been pursuing process improvements, including Fluor, Praxair, Kvaerner, MHI, ABB, Lummus and Crest. Currently, costs are reported to be in the range of about $30 to $40 per ton of CO_2, with R&D development goals set at about $20/ton CO_2. Advanced amine absorption processes may hold promise for intermediate-term CO_2 capture, with incremental (i.e., not breakthrough) reductions in costs. There is a critical need for large-scale pilot plant demonstration(s) on SO_2/NO_X-laden, coal-fired flue gas before more definitive projections can be made. Research breakthroughs and innovation in applications can certainly be significant, but are do not yet appear to be within the range of practicality.

Gas Separation Membranes

Gas separation membrane technology uses gas-liquid or catalyzed liquid membrane separators or reactors to "pull" the CO_2 gas from the exhaust stream. They may potentially use unique physical solvents, often still of a proprietary nature. Several potential vendors are currently actively involved in development of this concept or technology. These include Kvaerner, Carbozyme (catalyzed enzyme) and Electrocore (natural enzyme).

Temperature Swing Adsorption

Temperature swing adsorption concepts are similar in the use of custom-designed sorbents that adsorb CO_2 at lower temperatures, and then desorb CO_2 at higher temperatures. They include zeolites, synthetic zeolites, activated carbon (Adsorption Research, Inc./DOE). Though this technology holds promise for some time in the future, it is not ready for practical application today.

Regenerable CO_2 Sorbents

Regenerable CO_2 sorbent technology involves an absorption step for CO_2 removal, followed by a sorbent regeneration step where CO_2 is off-gassed. The process generally uses alkali and alkaline-earth metals (e.g., K_2CO_3 and CaO) deposited on a substrate. This technology is the focus of several ongoing research experiments. Advantages over amine-based liquid systems include: a) no large quantities of water involved in capture step and b) there are additional energy savings due to lower gas/solid pressure drop. RTI International (of RTP, NC) currently has efforts underway to develop this technology with support from DOE. Costs remain high with large energy use penalties.

The DOE has funded several such research projects that address the collection of CO_2 from stack gases of a coal-fired power plant. Except for amine absorption technologies, all CO_2 capture technologies still at the laboratory, bench-scale development level. Based on lab results, several vendors (Carbozyme, ARI) "claiming" projected full scale cost performances on the order of $5-15/ton CO_2 at some time in the future. These, and

[97] National Coal Council, "R&D Needs and Deployment Issues for Coal-Related GHG Management", May 2003.

other, potential "breakthrough" CO_2 capture technologies warrant further investigation and research investments but do not provide immediate promise or answers.

Geological Sequestration

The discussions immediately preceding relate to the capture of the gas in some form. This does not include transforming it to a stable and neutral element of the environment. One of the most promising means of disposal being researched is that of injection into geological strata such as subsurface coal mines, oil seams or deep underground brine "pools." Injection into oil or coal seams may also have some added benefit from production (release from strata) of methane that can be tapped and used in the utility boiler or for other purposes.

Obviously, these technologies require access to the proper strata for disposal of the waste stream before they might likely be considered viable. Eastern North Carolina may have some limited deep brine strata near the coast, but the state has no mines that would likely provide an opportunity for using this technology. Also, if such practical formations exist and prove feasible, there are currently no coal-fired (or other) boilers in that area, meaning that there would be additional transport costs to consider. The DOE recently announced the intent to develop an Environmental Impact Assessment of several brine strata. One of the potential formations to be assessed could be in Northeastern North Carolina. The proposal and Environmental Impact Assessment processes are time consuming, but prospects of information to be gained from evaluation of these formations is viewed as positive for the State. If the capture technology proves viable at some time in the future, it would be imperative to have a place to sequester the waste stream to render it harmless. The proposed DOE action would likely help answer these questions and a portion of the disposition puzzle for North Carolina. Such technologies might also influence location of future power generation units. Even with such an alternative available, the costs of collection and disposal would remain high and would very likely result in large reductions in the efficiency and generation of useful power at any such plant.[98]

[98]Kevin Johnson, *Some Projected Add-On Control Options for CO_2 Reductions at a Coal-Fired Generating Unit*, URS Corporation, DAQ Mercury and CO_2 Workshop, Raleigh, NC, April 21, 2004 (see Appendix A).

Other Technologies and Emerging Options

Many technologies have been developed, or are in an advanced state of development, such that they fall into a gray area of categorization. Some may be feasible to apply almost immediately, yet others are still on the shelf for one reason or other. Some of these technologies could easily move to a more advanced stage with little time and notice.

Conversion of Coal Units to Gas Units

A few years ago, many industry experts believed that coal-fired electric generating plants were "dinosaurs."[99] Coal was under attack; natural gas was cleaner burning, plentiful and "inexpensive." Improvements in combined cycle gas burning units had increased their efficiency. Natural gas units were generally less expensive in terms of capital investment. However, as natural gas units began to come on line, the price of natural gas went up in response to the decline in supply. The price of gas rose almost 175 percent over five years. With current natural gas prices even the more efficient new gas plants can operate economically only during the very infrequent periods of peak demand. Use of natural gas should not be dismissed out of hand for future expansion, but it probably is not a top candidate just because of reduced air quality impacts. Demand, alternate uses of the fuel, price and questionable net impacts make it necessary to look very closely at options and alternatives before implementing any significant expansion of conversion from coal as a fuel to natural gas.

Coal Gasification

Though direct use of natural gas may not be the answer for coal replacement, use of coal gasification may provide a partial answer. Integrated Gasification Combined Cycle (IGCC) is a process[100] for converting coal partially or completely to combustible gases. It is not a new technology (from the early 1800's through the 1940's most fuel gas used for residential and commercial applications was fuel gas from gasification of coal or coke), but is undergoing renewed interest, research and development, especially following recent successful demonstrations of practical applications. Eastman Chemical has used the technology routinely and has now licensed many of their developments, as a "chemical engineering process." IGCC is billed as the next generation of the technology of choice.

Coal can be gasified in a number of ways. After conversion, the resulting gases - carbon monoxide, carbon dioxide, hydrogen, methane and nitrogen - can be used as fuels or as raw materials for chemical or fertilizer manufacture. Gasification is inherently a cleaner process because coal is not combusted and the relatively small volumes of "syngas" are easier to clean up than the much larger volumes of flue gases at a coal combustion plant.[101]

---

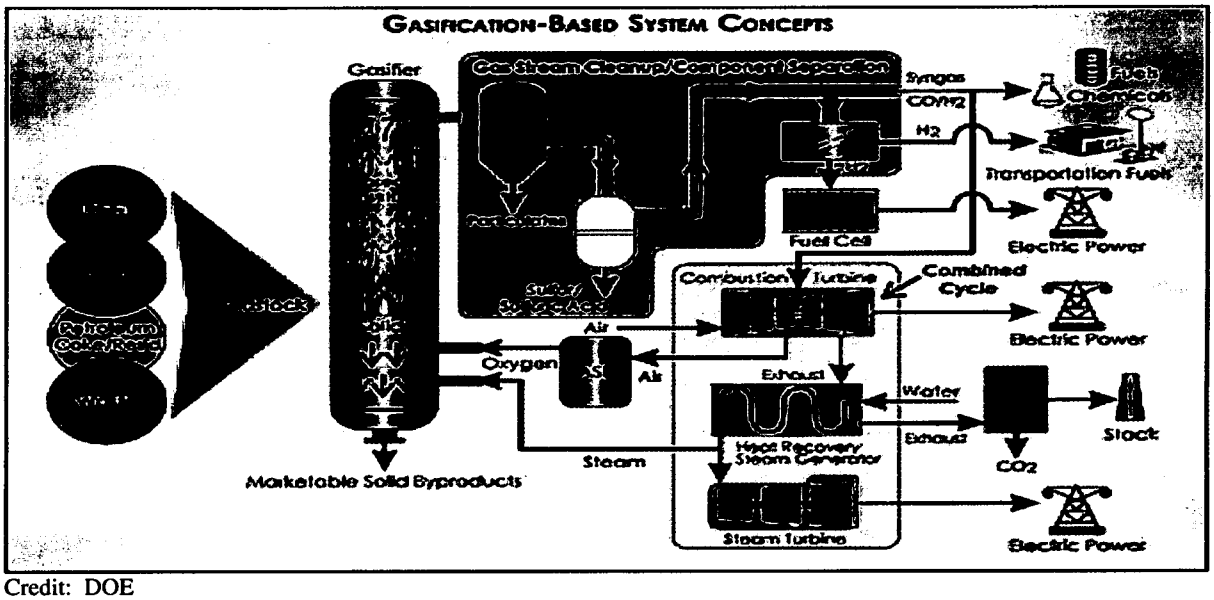
[100] E. L. Clark., ***Coal Gasification***, http://www.zetatalk.com/energy/tengy11a.htm.

[101] Joe Chaisson, Clean Air Task Force, ***Integrated Coal Gasification Combined Cycle (IGCC) Power Plants and Geologic Carbon Sequestration***, DAQ Mercury and CO_2 Workshop, Raleigh, NC, April 21, 2004 (See Appendix A).

The first pioneering coal gasification electric power plants are now operating commercially in the United States and in 49 other nations. [102] Many experts predict that coal gasification will be at the heart of the future generations of clean coal technology plants for several decades into the future. Rather than burning coal directly, gasification breaks down coal, or virtually any carbon-based feedstock, into its basic chemical constituents. In a modern gasifier, coal is typically exposed to hot steam and carefully controlled amounts of air or oxygen under high temperatures and pressures. Under these conditions, carbon molecules in coal break apart, and set chemical reactions into motion that typically produce a mixture of carbon monoxide, hydrogen and other gaseous compounds. Gasification may be one of the best ways to produce hydrogen for future automobiles and power-generating fuel cells. Hydrogen and other coal gases may also be used to fuel power-generating turbines or as the chemical "building blocks" for a wide range of commercial products. DOE's Office of Fossil Energy is working on coal gasifier advances that enhance efficiency, environmental performance, and reliability as well as expand the gasifier's flexibility to process a variety of feedstock (including biomass and municipal and industrial waste).

Figure IV-2: Schematic of Gasification Process



Credit: DOE

Environmental Benefits of Gasification

The environmental benefits of gasification of coal and other carbon-based fuels result from the process's capability to cleanse as much as 99 percent of the pollutant-forming impurities from coal-derived gases.[103] Sulfur for example, emerges as hydrogen sulfide and can be captured by processes routinely used today in the chemical industry. In some alternatives, the sulfur is extracted in an elemental form that can be sold commercially. IGCC plants can achieve low NOx emissions as the substantial amount of nitrogen

[102] DOE, Office of Fossil Energy, *Coal Gasification*, http://www.fe.doe.gov/programs/powersystems/gasification/.
[103] Ibid, *Coal Gasification.*

contained in coal is readily removed in the syngas clean-up process. Thus, NOx formation at an IGCC plant is primarily the result of thermal NOx produced at high temperatures in a combustion turbine.

The DOE Office of Fossil Energy is also exploring advanced syngas cleaning and conditioning processes that are even more effective in eliminating emissions from coal gasifiers. Multi-contaminant control processes are being developed that reduce pollutants to parts-per-billion levels and are effective in cleaning **mercury** and other trace metals, in addition to other impurities. Coal gasification may offer a further environmental advantage in addressing concerns over carbon dioxide. If oxygen is used in a coal gasifier instead of air, carbon dioxide is emitted as a concentrated gas stream, making it more viable and inexpensive to capture for ultimate disposition in various sequestration approaches. (By contrast, when coal burns or reacts in air, 80 percent of which is nitrogen, the resulting carbon dioxide is much more diluted and more costly to separate from the larger mass of gases flowing from the combustor or gasifier.)

Efficiency Benefits

Coal gasification also results in significant efficiency gains. In a typical coal combustion plant, heat from burning coal boils water, to make steam that drives a steam turbine-generator. Only about *a third* of the energy value of coal converts to electricity by most combustion plants. The rest is lost as waste heat. A coal gasification power plant typically gets dual duty from the gases that it produces. First, the coal gases, cleaned of their impurities, are fired in a gas turbine, much like natural gas, to generate one source of electricity. The hot exhaust of the gas turbine is then used to generate steam for a more conventional steam turbine-generator. This dual source of electric power, called a "combined cycle," converts much more of coal's inherent energy value into useable electricity. The fuel efficiency of a combined cycle power plant using gasified coal can thus be boosted to about 50 percent or more. Future concepts that incorporate a fuel cell or fuel cell-gas turbine hybrid will likely achieve even higher efficiencies, perhaps in the 60 percent range, or nearly twice today's typical coal combustion plants. With remaining waste heat being channeled into process steam or heat, perhaps for nearby factories or district heating plants, greenhouses, etc. the overall net fuel use efficiency of future gasification plants could possibly reach 70 to 80 percent.

Higher efficiencies translate into more economical electric power and potential savings for ratepayers. A more efficient plant also uses less fuel to generate power, meaning that proportionally less CO_2 is produced. Coal gasification power processes under development by DOE could cut the formation of CO_2 by 40 percent or more compared to today's conventional coal-burning plant. The capability to produce electricity, hydrogen, chemicals, or various combinations while virtually eliminating air pollutants and greatly reducing generation of GHG emissions makes coal gasification one of the most promising technologies for the energy plants of tomorrow. Many contend that its day has come and can be used as off-the-shelf technology, with continuing improvements.[104]

---

[104] Joseph Chaisson, Integrated ***Coal Gasification Combined Cycle (IGCC) Power Plants and Geologic Carbon Sequestration***, DAQ Mercury and CO_2 Workshop, Raleigh, NC, April 21, 2004 (See Appendix A).

Carbon Capture

From a climate perspective, a significant advantage of IGCC is that technology exists to remove carbon from syngas at a reasonable cost. Once captured, carbon can be compressed and transported to an appropriate site for injection into a suitable geologic formation for indefinite sequestration from the atmosphere as discussed earlier. All parts of this "carbon capture and sequestration" technology are in commercial practice today, but would need to be "up-scaled" to meet the requirements for a commercial IGCC utility plant.

Combined Cycle Turbines

Combined cycle turbines[105, 106] are relatively large stationary turbine units that are most frequently fueled by natural gas and used as intermittent peaking capacity for high load times. Some of the same, or similar, efficiency enhancements that were described above for IGCC can apply to these units. Combined cycle systems are capable of breaking the 60 percent efficiency barrier. They integrate the gas turbine, steam turbine and heat recovery steam generator into a seamless system, optimizing each component's performance. These units use higher efficiency and output to reduce the cost of electricity of this gas-fired power generation system.

Most existing units are open loop air-cooled gas turbines that have a significant temperature drop across the first stage nozzles, which reduces firing temperature. The combined cycle or closed-loop steam cooling systems allow the turbine to fire at a higher temperature for increased performance, without increased combustion temperatures with their usual increased emission levels of NOx. This closed-loop steam cooling enables them to achieve 60percent fuel efficiency capability while maintaining strict low NOx standards and reducing CO_2 emissions. Additionally, closed-loop cooling minimizes parasitic extraction of compressor discharge air, thereby allowing more air to flow to the head-end of the combustor for fuel premixing. They also offer a greater than 40 percent reduction in land area per installed megawatt, compared to other combined cycle systems, which helps reduce the overall cost of producing electricity. This technology is already in use at several plants in the State. Progress Energy's Cape Fear plant, for example, has two combined cycle units that power turbines from the original boilers at the site.[107] Several other new combined cycle units have also been built in the State and should be considered strongly in reviews and evaluations of new or modified units in the future.

Distributed Generation

Distributed generation applies to various schemes and methods whereby fuel, such as pipeline natural gas (locally generated methane from animal waste, etc), is distributed to small electrical generating units which then do not necessarily have to be connected to the electrical grid to satisfy the need of the individual customer. These generating units may be in the form of fuel cells, turbines or reciprocating engines (spark or diesel) and

---

[107] Cheryl Vetter, Progress Energy- *Comments on the Draft CO_2 Emissions Reduction Options for Coal-fired Electrical Utility Boilers and Other Stationary Sources, Second Interim Report,* August 6, 2004.

generally eliminate much of the line losses associated with the current distribution system (on the order of 10 percent of electricity generated is lost in line losses). However, these "small" units are generally not as efficient as a central unit with larger output, may be noisy, may be prone to abandonment or low maintenance practices, have the limitations of releasing their emissions (most likely NOx as the major pollutant of concern) at ground level, are not amenable to reliable emission controls and may have other environmental shortfalls. In addition, to function most efficiently there may need to be connections to the grid anyways for dependability of service and sale of excess production to the grid, when/if net metering legalities are resolved.

The potential for distributed generation is quite large. Some distributed generation sites, such as an animal waste fuel facility, could potentially become economic development zones where a single generator could serve the electrical needs of multiple facilities within that zone, or perhaps a nearby residential neighborhood.

For distributed generation to reach its potential in North Carolina, a change in the current utility territorial law may be required. At the current time, an entity wishing to sell the output from a distributed generation system to an end-use customer may, possibly, not be able to do so without becoming a regulated utility in NC, unless the entity is either an electric cooperative or a municipal electric system. It is unlikely that an entrepreneur will want to become a regulated utility subject to the various reporting requirements.

Hydrogen Fuels & Fuel Cells

A fuel cell uses the chemical energy of hydrogen to produce electricity and water, cleanly and efficiently. Fuel cells are unique in terms of the variety of their potential applications; they can provide energy for systems as large as a utility power station and as small as a smoke detector.

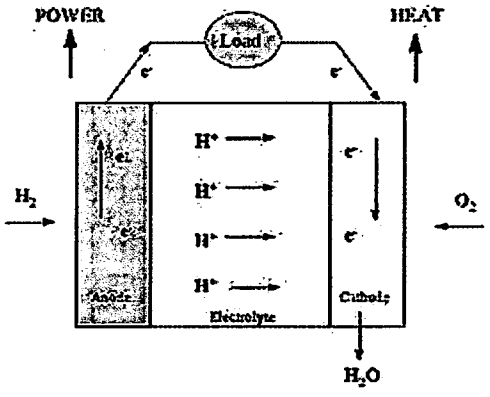
Hydrogen production and its combustion either in fuel cells or in "open flame" technologies have the potential to solve several major challenges facing America today: dependence on petroleum imports, poor air quality, and GHG emissions. DOE's Hydrogen, Fuel Cells & Infrastructure Technologies Program[108] is working to accelerate the development and successful market introduction of these technologies. The IGCC process referenced above is a potential building block for production of hydrogen from coal. In addition, work is progressing for direct use of coal in fuel cells. Some of this work was pioneered in the National Aeronautics and Space Administration (NASA) work preliminary to space travel. Research and developments of both hydrogen production technologies and those that provide for its effective uses as a clean burning fuel are "almost accessible" and the expectations for their application are high in the next few years. As noted above, IGCC technologies can easily provide a hydrogen stream for use to fuel these devices or other purposes needing hydrogen.

Fuel cells have several benefits over conventional combustion-based technologies currently used in many power plants and passenger vehicles. They produce much smaller

[108] U.S. DOE, Hydrogen, Fuel Cells & Infrastructure Technologies Program, http://www.eere.energy.gov/hydrogenandfuelcells/ .

quantities of GHG that contribute to global warming and none of the air pollutants that create smog and cause health problems. If pure hydrogen is used as a fuel, fuel cells emit only heat and water as a byproduct, though higher temperature applications have the potential to generate some NOx. Obviously, this technology is not yet available off the shelf for replacement of coal fired electrical generation but seems to have promise. Also, the cost factors are somewhat elusive at this point. As the technologies develop further, one can reasonably expect that these factors will be better defined and a sensible and reliable analysis of their potential (cost) impact on the market place can be developed. A simple rendering of how a fuel cell works is shown in Figure IV-3.

Figure IV-3
How a Fuel Cell Works[109]



Recovery of Fuel Value from Animal Waste at CAFOs

Confined animal feeding operations (CAFO's) generate huge quantities of waste high in carbon, and usually ammonia. Research underway for several years in North Carolina at the North Carolina Animal and Poultry Waste Management Research Center on the North Carolina State University (NCSU) campus and at several other agricultural campuses throughout the country is attempting to develop better means of disposal of animal waste, with recovery of resource value. North Carolina is the second largest hog producer in the US, with approximately 10 million pigs, thus at NCSU, the focus of these activities has been primarily on swine operations. In 2000, Smithfield Foods and the North Carolina Attorney General's Office entered into agreements to fund and study "promising new technologies" with expectation that these would provide solutions to the ammonia and odor problems in particular, and to waste disposal problems in general.

Results of this program have been recently unveiled. The reports will soon be available, but some of the promising technologies studied included methods and processes to turn the carbon in the waste into fuels for distribution as an energy source. This program will continue to pursue many of the technologies and make them more economically viable, but the conversion options, in particular, may hold promise for supplementing the fuel supply at no large expense on the CO_2 budget, providing another source of carbon fuel that does not depend on fossil fuels. At the DAQ Mercury and CO_2 workshop, Kurt

[109] NASA, *How a Fuel Cell Works*, http://www.grc.nasa.gov/WWW/Electrochemistry/doc/fuelcell.html.

Creamer, P.E., one of the researchers from NCSU, who has been working on this project with Dr. Mike Williams, Director of the Smithfield Agreement Project, discussed these efforts.[110] Reports from the research are currently being released and the studies will likely result in several papers and other technical documents soon. As for other potential electric sources, the net metering and other related legalities may need to be addressed before all the roadblocks are removed.

Nuclear Power

Despite other environmental and social impacts, nuclear does have substantial air quality and CO_2 benefits. Nuclear power is basically a clean (air pollution-wise), non-CO_2-emitting source of electric power. A new nuclear power plant has not been built in the U.S. in the last couple of decades, but DOE is currently in the process of "dry-run" permitting new nuclear capacity. Finland, Japan and Taiwan have also recently announced new nuclear plants. Reluctance to build such capacity has been largely due to fear of or potential for releases of nuclear radiation and because of the lack of long-term, safe storage and disposal facilities for "spent" nuclear fuels. The more recent fear of, or actual potential, for some of these fuels falling into the hands of terrorists and others has not helped enhance the chances of new plants being constructed. Many design improvements for safety have been made in reactors since the last units were built here, and reactors continue to operate and be built in other countries. Whether, or when, these units may enjoy serious further consideration in North Carolina is uncertain, but that uncertainty does not dismiss this option from being on this list.

Industrial Initiatives

The private sector often has motivation and commitment to make reductions on their own. Though the point here is not to show a complete cross-section of such efforts, several companies have developed a strong environmental reputation by "going the extra mile" and demonstrating their good citizenship. Two examples that operate in North Carolina are mentioned below:

- DuPont has become a leader in safety issues as well as several environmental areas. For CO_2 reduction results, it has undergone massive programs to revamp the way it does business and manufactures products. For example, the company as a whole, used nine percent less total energy in 2002 than it did in 1990, despite an almost 30 percent increase in production. The resulting energy savings were nearly $2 billion. Mr. William Bailey of DuPont made a presentation at the DAQ Mercury and CO_2 Workshop in April 2004 and his presentation slides are available that summarize their efforts and results.[111]

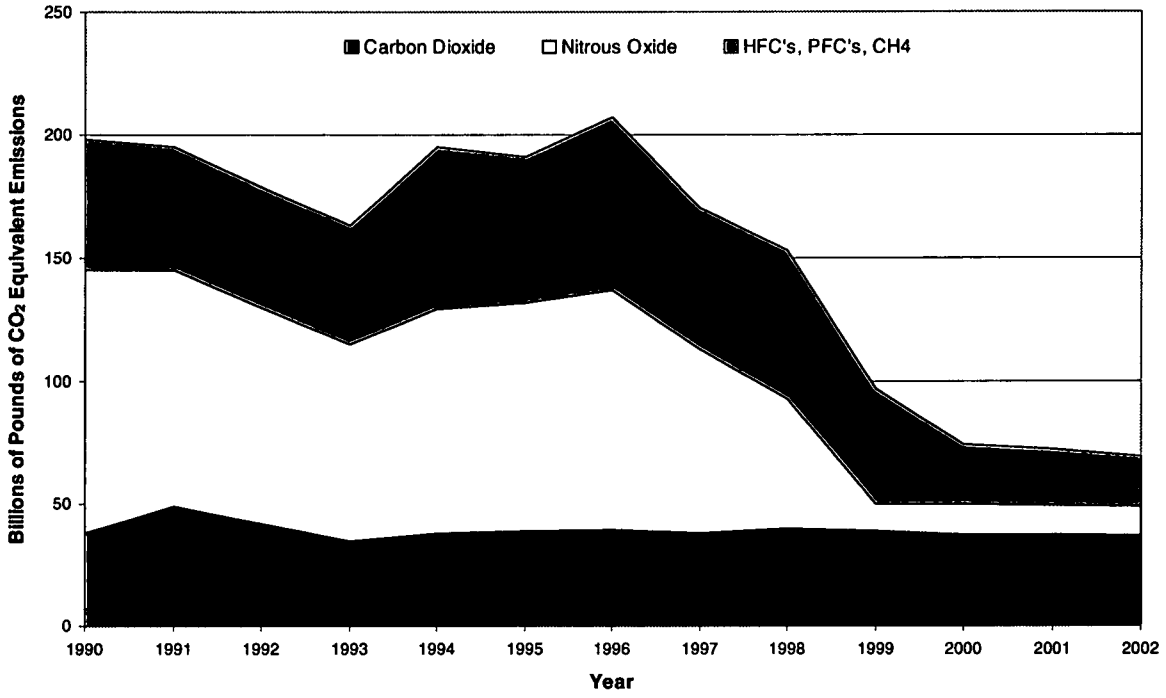
Charlotte, NC, *Reducing Greenhouse Gas Emissions in DuPont,* Presentation at DAQ Mercury and CO_2 Workshop, Raleigh, NC, April 21, 2004. http://daq.state.nc.us/news/leg/2004-04-hg-co2-agenda.pdf . (See Appendix A)

Figure IV-4: Emission Reductions at DuPont 1990-2002



- IBM provides another example of such an environmentally forward-looking company. Between 1990 and 2002, IBM's energy conservation measures resulted in savings of 12.8 billion kilowatt hours of electricity, avoiding nearly 8 million tons of CO_2 emissions and saving the company $729 million in reduced energy costs.

Other Potential Policy Options for North Carolina

Although already covered to some degree by the SEO's energy plan discussed above, several particular energy related policies seem appropriate for further discussion and added emphasis. These policy options do not necessarily relate to hardware or technologies so much as to a means to an end different from what is now in place.

Renewables Portfolio Standards:

One way to encourage increased use of renewable sources of energy as already discussed in this report, is to establish a Renewables Portfolio Standard (RPS). The RPS is a flexible, market-driven policy that can help ensure that the public benefits of wind, solar, biomass and geothermal continue to be considered for their maximum contributions toward using less energy and the accompanying reductions in CO_2 emissions as electricity markets become more competitive. RPS can help ensure that some minimum amount of renewable energy is included in the portfolio of electricity resources serving the State, and, by increasing the required amount over time, the RPS can put the electricity industry on a path toward increasing their sustainability. Because RPS is a market standard, it relies almost entirely on the private market for implementation.

Market implementation will normally result in competition, efficiency and innovation that will deliver renewable energy at the lowest possible cost.

Renewable Energy Credits, or "Credits," are central to RPS. A "credit" is a tradable certificate of proof that a specific number of kilowatt-hours (kWh) of electricity have been generated by a renewable-fueled source. Credits are denominated in "kWh," and are a separate commodity from the power itself. The RPS requires all electricity generators (or electricity retailers, depending on policy design) to demonstrate, through ownership of credits, that they have supported an amount of renewable energy generation equivalent to an established percentage of their total annual kWh sales. For example, if the RPS is set at 5 percent and a generator sells 100,000 kWh in a given year, the generator would need to possess 5,000 credits at the end of that year.

With RPS, investors and generators make all decisions about how to comply, including: the type of renewable energy to acquire, the technologies to use, the renewable developers to do business with, the price to pay and the agreeable contract terms. Generators decide whether to invest in renewable energy projects and generate their own credits, enter into long-term contracts to purchase credits, or renewable power along with credits, or simply to purchase credits on the 'spot' market. Only the bottom line is enforced, i.e. possession of a sufficient number of credits at the end of each year. The credit system provides compliance flexibility and avoids the need to "track electrons." Because the RPS applies equally to all generators, it is competitively neutral.

Government involvement in RPS is usually limited to certifying credits, monitoring compliance and imposing penalties if necessary. The credit certification process applies to renewable producers who wish to certify their renewables output. Monitoring compliance requires each generator to demonstrate ownership of a sufficient number of credits relative to electricity sales.

Fourteen states have adopted RPS requiring that a certain percentage of their electricity be generated by renewable energy. These are Arizona, California, Connecticut, Iowa, Maine, Massachusetts, Minnesota, Nevada, New Jersey, New Mexico, New York, Pennsylvania, Texas and Wisconsin.[112] Although North Carolina has not adopted a full RPS, the NC GreenPower program is essentially an adaptation of the concept which may serve to demonstrate how other similar actions on a broader scale might work in the State.

Net-Metering

"Net Metering" is a special metering and billing agreement between utilities and their customers that facilitates the connection of small energy generating systems (conceivably both renewable and conventional) to the power grid. These programs encourage small scale renewable energy systems, ensure that customers always have a reliable source of energy from the grid during times when their generators are not producing energy, and provide substantial benefits to the electric system, the economy and the environment.

---

[112] Amy Royden-Bloom, ***Reducing CO_2 from Coal-Fired Utilities: State and Local Initiatives***, DAW Mercury and CO_2 Workshop, April 21, 2004, Raleigh, NC. (See Appendix A).

When a customer's renewable generator is producing, more power than is being consumed, the customer's meter runs backward, generating credits. When a customer uses more power than is being produced, the meter runs forward in a normal manner. The customer is charged only for the "net" power used from the electricity service provider over a designated period.

Distributed generation is also discussed later in this report and is closely associated. For distributed generation to reach its maximum potential in North Carolina, changes in the utility territorial law may be required. Now, an entity wishing to sell the output from a distributed generation system to an end-use customer may not be able to do so without becoming a regulated utility in NC, unless the entity is already an electric cooperative or a municipal electric system. By revising these laws and adopting net metering laws, states encourage the installation and use of renewable energy generators such as those produced from animal waste. Such systems may help lessen our dependence on domestic and foreign fossil fuels, add to the diversification of our current energy portfolio and help lessen the environmental footprint associated with electricity generation and consumption. Customers with net metering systems are likely to be more aware of their energy consumption and consume less energy than the average customer. Net metering is also a way to increase the energy in the power grid to keep up with increases in demand during peak power-use times, which is particularly of interest to states facing power shortages.

Currently, 37 states require at least some utilities to offer net metering for small wind systems, although the requirements vary considerably. In recent years many states have enacted net metering laws, including California, Connecticut, Delaware, Massachusetts, Montana, Nevada, New Hampshire, New Jersey, Ohio, Oregon, Vermont, Virginia, and Washington. North Carolina is one of only 11 states without some form of net metering.[113] In most states with net metering statutes, utilities are required to offer net metering for renewable systems, although many states limit eligibility to small systems.

State Energy Plan Priority # (6) is a recommendation that the General Assembly should consider adopting net metering for all utilities. **Status**: Discussions are underway on net metering and interconnection issues between utilities, renewable energy advocates and generators. A NCUC docket, related to NC GreenPower program, is being developed.[114]

NC Climate Action Registry

Much discussion has occurred in North Carolina on a climate change or climate action registry that would establish and supplement existing voluntary reporting programs. Such a registry would provide a mechanism to track all GWG emissions. However, a registry alone will not necessarily accomplish any major reductions. Without inclusion of all emitting sources in the inventory and registry to determine and track the true rate of increase (or decrease) of emissions from activities within the state, a complete and

---

[113] Rusty Haynes, North Carolina Solar Center, *Database Empowers Economic Development*, Carolina Sun, Summer 2004.

[114] Larry Shirley, Director, State Energy Office, *Development, Components and Status of the NC State Energy Plan*, Presentation at NC DAQ Mercury and CO_2 workshop, Raleigh, NC, April 19, 2004 (See Appendix A).

accurate assessment of the total is impossible. The two major contributing sectors (coal fired power generation and transportation) are otherwise already reporting or can be tracked independently of a traditional registry. The EPA National Acid Precipitation Program already mandates continuous measurement and annual reporting of their emissions, and these are available from the national database. In addition, North Carolina utilities are reporting to DOE's 1605 (b) voluntary registry. Emissions from transportation sectors can be reasonably estimated by tracking fuel usage and translation of these data into CO_2 by simple chemical reaction calculations.

There are already several competing registries (World Resources Institute, 1605b, the Greenhouse Gas Protocol, a developing ISO standard, Climate Leaders) all with different thresholds, methods and requirements. Sources are likely to participate in a voluntary registry only if it provides them with an indication of success while other facilities that are not able to paint such a picture of their situation are less likely to voluntarily report. Thus, a national registry should be revised so that it will provide an overall program of complete assessment and tracking of all sources.

A draft discussion plan for a North Carolina registry and intermediate steps toward reaching the goals of such a program are outlined in **Appendix C**. This plan is <u>not a recommended plan</u> but is provided to point out some of the needs, and requirements to be defined, and choices to be made, before implementing such a program. The reader should review the plan and arguments, and provide comments upon a better design and means for implementation of such a proposed registry, should it become determined as a requirement or need. The draft plan in **Appendix C** will no doubt be further revised to reflect comments from reviewers of this document. Such comments will hopefully include response to the basic concept of further development of a more "Comprehensive North Carolina Plan for GHG Mitigation," or other some other multi-state integrated programs suggested in this draft. Many of the components of this draft are speculative and dependent upon future developments outside of the control of DAQ.

CHAPTER V WHAT ARE OTHERS DOING

In a democratic society, the people, through their elected officials, may set policies based upon what they feel is most important. These policies will be reflected at all levels, from international, national, down through state and local. The actions of other jurisdictions may provide insights, or perhaps clues, as to where these directions may take us, at least in context to what is done in North Carolina related to these other jurisdictions. This section reviews some of the existing situations and policies.

Update on International Developments

There are few recent international milestones. The Kyoto treaty[115] was being considered in 1997 and at that time, the Senate passed the Byrd/Hagel Resolution stating that the United States should not sign on to any international agreement on limiting greenhouse gases if developing nations would not be required to adhere to limitations, or the agreement would cause harm to the U.S. economy. In 1999, the Clinton Administration agreed to legally binding, numerical limits on GHG as prescribed by the Kyoto Treaty. The Bush. Administration continues to agree with general principles of the climate change efforts and needs for action, but opposes the Kyoto Protocol. In 2002, President Bush directed the Department of Energy[116] to improve its guidelines for voluntary reporting of GHG emissions, reductions and avoidance in an effort to appease some of the criticisms of its policies. A history and more details on the international situation are included in Appendix B.

Another major world leader in a similar situation to the U.S. is Russia. It initially signed the protocol,[117] but later decided not to ratify it and recently again reversed its stance. Though a large number (122 as of April 15, 2004) of countries have accepted, ratified, or otherwise approved, the Protocol, and it remains open for additional signatures in the UN in New York City, it appears a major event and redirection will be needed to keep this Protocol from a slow continuing march toward death. In addition, in the past several months, the international bodies met in Italy for their periodic general conference and continued discussions.

Federal Actions and Status

The Bush Administration continues to agree that global warming is a major problem and that we must take action, but continues to oppose the Kyoto Protocol. Just as this report was being finalized, new announcements were made about how the Administration was recognizing that emissions of CO_2 and other GWG are "the only likely explanation for global warming over the last three decades."[118] However, the directions to date and proposals extended for the future, are aimed at slowing the pace of growth, instead of reversing the phenomenon. The U.S. Congress plays a key role in how the U.S. responds

[117] Russia: Kyoto pact harms economy, CNN.com, December 2, 2003, http://www.cnn.com/2003/WORLD/europe/12/02/russia.kyodo.reut/.

[118] Andrew C. Revkin, *U.S. Report Turns Focus to Greenhouse Gases*, Greenwire, August 26, 2004.

to the challenges of global climate change. Legislation will be necessary to reduce GHG in any significant way. In addition, the Senate must ratify any treaty made by the U.S. This gives the Senate a major role in any international agreements and action plans. The budgets of all federal agencies, which include funding for programs to curb U.S. emissions, are established in the agencies' annual spending (or appropriations) bills. Congress then conducts hearings on these proposals.[119]

International climate change agreements must be ratified by the U.S. Senate for the United States to be a party, giving the Senate major influence over the U.S. negotiating position. The budgets of all federal agencies, which include funding for programs to curb U.S. emissions, are established in the agencies' annual spending (or "appropriations") bills, enacted by Congress. Congress conducts hearings that focus attention on global climate change and shape the national debate over how best to address it. With climate change, as with other issues, congressional action can differ significantly from that recommended by the U.S. President.

Members of both the Democratic and Republican Parties have offered climate change measures. As the scientific evidence of climate change has mounted, so has congressional activity. The number of climate change related legislative proposals increased from seven introduced in the 105th Congress (1997 - 1998) to twenty-five in the 106th Congress. Legislative proposals to require reporting and disclosure of GHG emissions and to protect companies from future penalties for reductions taken early seem to dominate. Many proposals are also aimed at carbon sequestration. An eventual program that is more comprehensive and possibly including a mandatory reduction of emissions, while allowing trading emission credits and rewards for increases in efficiency, may be slowly evolving. The forty-five bills, resolutions and amendments specifically addressing global change and GHG emissions introduced to date in the 108th Congress are listed in Appendix B.

Interest appears to be growing in certain legislative proposals, including measures to require the reporting and disclosure of GHG emissions, protect companies reducing GHG emissions from being penalized under a future GHG reduction program, and to promote carbon sequestration. Two bills have had bipartisan support. In the Senate, the *McCain-Lieberman Climate Stewardship Act of 2003* proposed capping GHG emissions of the electricity, manufacturing, commercial and transportation sectors of the economy (representing 85 percent of U.S. emissions) at their 2000 level, by 2010, and their 1990 level by 2016. Emitters would be able to trade GHG emissions credits and get credit for pre-enactment GHG reductions, carbon sequestration and international GHG reductions, up to a limit. The bill lost by a vote of 55 to 43, but Senator McCain has vowed to continue pushing this legislation until the Senate passes it. In March 2004, 20 members of the House (10 Republicans and 10 Democrats) introduced *Gilchrest-Olver Climate Stewardship Act of 2004* that echoes language of the McCain-Lieberman bill. It would require U.S. industries to reduce emissions of six primary GHGs from four sectors to 2000 levels, by 2010.

---

[119] Worldwatch Institute, *Climate Change: Reducing the Threat of Climate Change in the U.S.: A Survey of Activities*, 2004. http://www.worldwatch.org/features/climate/activities/#1

In addition, two bills and several amendments were introduced to set up GHG registries. *The National Greenhouse Gas Emissions Inventory and Registry Act of 2003* was introduced in both the House and Senate, and would require large GHG emitters to report and disclose their emissions. Entities could also register their GHG reductions. *The Energy Policy Act of 2003*, which won approval by a vote of 84-14 in the Senate, includes three climate change titles. Title XI would establish a voluntary National GHG Registry. It also conditions that if, five years after enactment, less than 60 percent of U.S. anthropogenic GHG emissions had been reported voluntarily, reporting would be mandatory for large GHG emitters. The title also would encourage any future Congress to consider registered reductions as applicable towards future GHG reduction requirements. The bill establishes a *National Climate Change Strategy* with the goal of stabilization of GHG concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. It would also establish an Office of National Climate Change Policy within the White House, and a research and development program toward the goal of stabilization of GHG concentrations. A similar bill awaits passage in the House.

Addressing the challenge of climate change may ultimately include a more comprehensive set of approaches, possibly including a mandatory program to reduce GHG emissions and allow the trading of GHG emissions credits, and efficiency standards to promote the use of efficient products and technologies. Enacting such policy may be a longer-term proposition.

Pursuant to existing federal legislation and programs, several named efforts and programs are underway. These include Climate VISION, Climate Leaders, Climate Wise, the DOE 1605 (b) Registry and several others that cross Cabinet and Agency lines among EPA, DOE, USDA, NOAA, NASA, etc. Some are research oriented, some are mitigation oriented. Many of these programs are discussed in more detail in a separate context elsewhere in this document.

State and Regional Activities

The Pew Center for Global Climate change lists 28 different states with 44 state and local programs that reduce greenhouse gas emissions. Some programs were designed specifically to address climate change, but many were designed for other purposes: for example, to improve energy efficiency or to promote water conservation. All, however, directly or indirectly result in greenhouse gas reductions. During 2003 alone, at least 24 states introduced 90 bills to build frameworks to regulate GHG emissions. One-quarter of all U.S. states have enacted Renewables Portfolio Standards (RPS), which mandate an increase in the states' share of electricity generated with renewable energy. About half of all U.S. states have established renewable energy funds to provide subsidies for installation of renewable energy projects, or for the production of renewable electricity, for energy efficiency projects, and for energy education and awareness programs.

A few multi-state efforts exist. In 2003, the governors of California, Oregon, and Washington began efforts to draft recommendations on ways to collaborate regionally in reducing emissions in several sectors of their economies, including using more efficient

vehicles, increasing the share of renewables in electricity generation, and creating emissions accounting systems and inventories. Also in 2003, New York invited the governors of 10 other states to participate in the development of a regional program to cap and trade CO_2 emissions. Design for this Regional Greenhouse Gas Initiative is planned for completion in 2005.

In some relation to this effort is that by the North East States for Coordinated Air Use Management (NESCAUM) with many of the same states. The NESCAUM has initiated significant efforts toward their objectives through their Regional GHG Initiative (RGGI). The goal of their efforts is to develop the framework for a power sector GHG cap and trade system. They also plan to have a model rule in place by April 2005. Nine states are officially participating as members in this effort; with two states officially 'observing' and others invited. North Carolina is evaluating whether to become an official observer, but in the meantime is an unofficial observer.[120]

Option for Joint Actions Harmonizing With Other States

North Carolina provides only a small part of the global emissions of GHG, making it rather obvious that this State cannot solve the global problem alone. The State must work in consonance with other states in the region and United States, and even with other countries over the entire globe. We must take into account some perspective of what other states and groups of states are doing to address the problem. It is imperative that we be in harmony with them and with the international community in order to develop and utilize a "currency" for exchange and record keeping that is universal and does not impose unneeded hardships on reporting and controlling facilities.

The development of ways to reduce GHG and establish North Carolina as a truly important "part of the global solution" is not simple or something that can be done in isolation. Perhaps, the development of an integrated regional, multi-state, multi-departmental approach encompassing climate change, air quality and energy could assist in arriving at a solution that would do the job and be accepted as credible. A means for doing such planning and implementation would likely require some strong initiatives from the top levels of state governments, appropriation of resources, development of a motivated group of stakeholders, plus time, leadership and patience. Three recent reports provide some insights, guidance and information on experiences and how such large-scale options might be exercised.[121,122,123] The further development of this concept may harmonize well with a "Comprehensive North Carolina Plan for GHG Mitigation" mentioned later in this report under the GHG Registry discussions. It is definitely a concept that warrants further study and evaluation.

APPENDIX A *APRIL 19-21, 2004 DAQ WORKSHOP PRESENTATIONS (CO_2 ONLY) TITLES, SPEAKER NAMES AND AFFILIATION*

DUE TO SIZE OF ELECTRONIC FILES, THESE PRESENTATIONS ARE NOT INCLUDED IN THIS VERSION OF THIS REPORT, BUT MAY BE SEEN AT DAQ'S WEBSITE:
http://daq.state.nc.us/news/leg/2004-04-hg-co2-agenda.pdf

Monday, April 19 Opening Session

Introduction and Welcome: Keith Overcash, Director, NC Division of Air Quality, DENR

Background and Significance of Clean Smokestacks Act: Brock Nicholson, Deputy Director, NC Division of Air Quality, DENR

Basis for Issues to be Discussed: CO 2 and Mercury:

Moderator, Sheila Holman, Chief, Planning Section NC Division of Air Quality

Review of the Science and Concerns for Climate Change in North Carolina: Ryan Boyles, Associate State Climatologist, State Climate Office of NC at NCSU

History and Transitions of the Global Warming Program and Policies in the US: Wiley Barbour, Environmental Resources Trust

Development, Components and Status of the NC State Energy Plan: Larry Shirley, Director, NC State Energy Office, NC Department of Administration

Lunch Speaker - Importance and Impacts of CSA Sections 12 and 13 and Your Input for the Future of North Carolina: Secretary William (Bill) Ross, NC Department of Environmental and Natural Resources

Tuesday, April 20

Environmental Leadership: The Pursuit of Clean Air: *Ben White, Progress Energy*

Renewable Energy as a Mechanism for Reducing Pollution: *Alden Hathaway, Environmental Resources Trust, Inc., Washington, DC*

Lunch Speakers

Mercury and CO_2 Emissions from the Power Generation Sector *: Dr. C.V. Mathai, Manager for Environmental Policy, Arizona Public Service Company, Phoenix, AZ*

Insights from Economic Analyses of the Impacts to the Utility Industry from Mercury and CO_2 Controls*: Dr. Anne E. Smith, Vice President, Charles River Associates, Washington, DC*

General CO_2 Topics and Issues:

Moderator, Phil Bisesi, Project Manager, North Carolina State Energy Office

Potential Impacts for the NC State Energy Plan on Emissions of CO_2 with Technical Procedures and Assumptions Upon Which These Plans Were Developed: *Jeff Tiller, Appalachian State University*

Technology, Energy Efficiency, and Renewable Energy for Emission Reduction: *Ward Lenz, Director, Energy Programs and John Morrison, Vice President, Advanced Energy*

The People, the Planet, and the Pocketbook: How a Green Builder Program Can Avoid Emissions Using Solar Energy: *Dona Stankus, AIA, NC Solar Center*

Potential in NC for Extraction of Wind Energy : *Dr. Dennis Scanlin, Professor, Technology Department, Appalachian State University*

Past, Present and Projected Participation in Climate Wise by North Carolina Companies: *James Haven, Global Warming Initiatives, Inc.*

Wednesday, April 21 : NC Specific CO 2 Topics and Issues–

Moderator: Phyllis D. Jones, NC Division of Air Quality

Review of Real/Practical and Projected Options fro CO_2 at a Coal-Fired Generating Unit: *Kevin Johnson, URS*

Integrated Gasification Combined Cycle (IGCC) Technology; Carbon Sequestration and Cost Implications : *Joe Chaisson, (Harpswell, ME), Clean Air Task Force (Boston, MA)*

The Global Carbon Cycle and the Duke Forest Free-Air CO_2 Enrichment (FACE) Project: *Dr. William H. Schlesinger, Dean, Nicholas School of the Environment & Earth Sciences, Duke University.*

NC Animal Waste as a Potential Resource for Reducing CO_2 and Methane Emissions: *Kurt Creamer P.E., Animal and Poultry Waste Management Center, NC State University*

Industry Experience in Reducing CO2 and GHG Emissions – A Case Study of International Proportions: *Bill Bailey, DuPont, Charlotte, NC*

Reducing CO_2 from Coal-Fired Utilities: State and Local Initiatives: *Amy Royden, STAPPA/ALAPCO*

Lunch speaker – Herding Sheep: The Commons and the Marketplace; Michael Shore, Environmental Defense

Overview of the Southeast Regional Carbon Sequestration Partnership: Gerald R. Hill, Ph.D, Senior Technical Advisor, Southeastern Regional Carbon Sequestration Partnership

Summaries:

Integrated Gasification Combined Cycle (IGCC) Technology; Carbon Sequestration and Cost Implications : *Joe Chaisson, (Harpswell, ME), Clean Air Task Force (Boston, MA)*

IGCC: WHAT IS IT?

- Chemical conversion of coal to synthetic gas for combustion in a modified gas turbine.
- Inherently cleaner process because coal is not combusted and the relatively small volumes of syngas are easier to clean up than the much larger volumes of flue gases at a coal combustion plant.

IGCC Environmental Impacts –

General

- IGCC plants are more efficient in converting coal to electricity than conventional coal plants and thus produce less CO2 per unit of electricity generated.
- Near-term IGCC plants would produce about 20% less CO2 - per unit of electricity produced - than would the average existing coal plant.
- The longer term potential could be for IGCC plants to produce about one-third less CO2 - per unit of electricity produced - as would the average existing coal plant.
- IGCC plants can potentially capture and geologically sequester up to 90% (or more) of coal fuel carbon content.

Air Pollution

- Commercially available IGCC power plant technologies can have much lower air pollution emissions than new conventional coal plants.
- Actual air emissions performance will likely depend, at least in part, on what control technology and performance levels are required by regulators.

Waste

- Commercially available IGCC power plant technologies produce substantially smaller volumes (about one half) of solid wastes than do new conventional coal plants using the same coal.
- IGCC solid wastes are less likely to cause environmental damage than fly ash from conventional coal plants because IGCC ash melts in the gasification process, resulting in an ash much less subject to leaching pollutants than is conventional coal combustion fly ash.

Mercury Management

- Mercury capture at IGCC plants is quite feasible and much less costly than at conventional coal plants and the potential exists to indefinitely sequester mercury captured at IGCC facilities.
- Proven, low cost mercury controls can remove most of the mercury from coal syngas produced (14 years experience at Eastman Chemical).
- Mercury is captured in a small volume activated carbon bed. Bed contents are currently managed as hazardous wastes (due to other toxics captured), but could be sequestered in a long-term mercury storage facility or the mercury contained could be economically recycled.
- Thus coal IGCC with a carbon bed plant mercury control is the only technology today that can convert coal to power and capture most of the coal mercury in a form and volume suitable for permanent sequestration.

APPENDIX B *SUMMARY OF RECENT INTERNATIONAL, FEDERAL, REGIONAL, STATE AND LOCAL ACTIONS RELATED TO CLIMATE CHANGE*

International Actions, Treaties and Negotiations:

Framework Convention on Climate Change (Rio Climate Treaty)

Signed at Rio de Janeiro, Brazil in June 1992 by over 150 nations including the United States of America, the Rio Climate Treaty came into force in March 1994 and has been ratified or acceded to by virtually every nation including all populous countries except Turkey. The Rio Climate Treaty came out of the Rio Earth Summit and was signed by over a hundred heads of state and government including US President George Herbert Walker Bush. The Rio Climate Treaty sets an overall framework for climate protection and identifies as an objective for "stabilization of greenhouse gas concentrations in the atmosphere at a level that would produce dangerous anthropogenic interference with the climate system."

The Rio Climate Treaty does not set any binding emission limitations. It does, however, call for developed countries to adopt national policies and take measures "with the aim of returning individually or jointly" their net greenhouse emissions to 1990 levels. By the mid-1990s it was apparent that the voluntary measures of the Rio Treaty were not stopping the upward emissions trend in most industrialized countries so the parties to the Rio Climate Treaty began looking toward an emissions protocol with binding limitations on developed country parties. After two-and-a-half years of negotiations such a protocol was agreed to in December 1997 in Kyoto, Japan.

Kyoto Protocol

Even before the protocol was negotiated in final text in Kyoto, opponents in the US Senate sealed its doom with a 97-0 resolution expressing the sense of the Senate that the US should not sign an agreement which would either threaten the economic health of the US or which would impose binding requirements on the US without also imposing binding requirements on developing countries. While the first requirement might be met, there was no way that the Kyoto Protocol could meet the second requirement since developing countries had been guaranteed that they would be exempt from binding limitations.

The Kyoto Protocol ultimately set requirements for developed countries which, if agreed to and successfully implemented, would produce an overall reduction of just over 5% below developed country 1900 emissions by the 2008-2012 time frame that was set in the protocol as the first commitment period. In the absence of any international controls it is estimated that global emissions might rise about 40% by 2012. With Kyoto implemented by all developed countries it is anticipated that global emissions might rise by 30% over the same period.

G-8 Renewable Energy Initiative

In July 2000 at their Okinawa Summit the G-8, at the urging of British Prime Minister Tony Blair, agreed to create a Renewable Energy Task Force to address the challenge of two billion people lacking access to electricity. The Task Force drafted a Report that calls for G-8 member countries to support renewable energy actions in developing countries and to complement this with efforts in their domestic markets to scale up use of renewable energy. Prime Minister Tony Blair vowed that his country would seek to reduce its emissions of carbon dioxide by 60 percent by 2050.

Small Island States Clean Energy Initiative

In October 1998 the Climate Institute and Counterpart International organized a Symposium on Sustainable Energy Options for Small Island States. Present were the Foreign Minister of Jamaica, the UNDP administrator and senior staff, several USAID representatives and Permanent representatives from UN missions. An immediate outgrowth of this was the decision of the Caribbean nation of St. Lucia to become the world's first Sustainable Energy Demonstration Country. This was announced by the Government of St. Lucia at a press conference held jointly with the Climate Institute in November 1999 at the Bonn climate conference. Before making this announcement St. Lucia began steps to remove tariffs on renewable energy technologies and support equipment. In November 2000 St. Lucia's Prime Minister Dr. Kenny Anthony called on other countries at the Hague climate conference to follow St. Lucia's lead. In July 2001 the St. Lucia government approved a 10-year Sustainable Energy Plan.

Global Sustainable Energy Islands Initiative

Seeking to expand the Sustainable Energy Demonstration Country concept to other island nations, the Climate Institute and four partners — Counterpart International, Winrock International, Forum for Energy and Development and the Organization of American States — formed a consortium to support the interest of all small island states and potential donors by bringing renewable energy and energy efficiency projects, models, and concepts together in a sustainable plan for small island nations. At this time the two island states closest to joining St. Lucia in an effort to de-carbonize their energy systems are Grenada and Dominica, both in the Caribbean.

Iceland's Effort to Become First Hydrogen Based National Economy

Iceland whose per capita greenhouse emissions are among the highest in the world is now moving aggressively to become the world's first hydrogen-based economy. The country of about 270,000 has embraced a vision first put forth in the 1970s by Bragi Arnason, a professor at the University of Iceland. To reach its goal of becoming the world's first hydrogen-based national economy Iceland seeks to leverage its access to plentiful inexpensive hydro and geothermal power to speed commercialization of fuel cells for transport and power generation.

Federal Actions from the 108TH Congress Relative to Climate Change

The U.S. Congress plays a key role in determining how the United States responds to the challenge of global climate change. Legislation, enacted by Congress, will be necessary to reduce U.S. emissions of greenhouse gases substantially. International climate change agreements must be ratified by the U.S. Senate for the United States to be a party, giving the Senate major influence over the U.S. negotiating position. The budgets of all federal agencies, which include funding for programs to curb U.S. emissions, are established in the agencies' annual spending (or "appropriations") bills, enacted by Congress. Congress conducts hearings that focus attention on global climate change and shape the national debate over how best to address it. With climate change, as with other issues, congressional action can differ significantly from that proposed by the U.S. President.
As the scientific evidence of climate change has mounted, so has congressional activity. The number of climate change-related legislative proposals increased from seven introduced in the 105th Congress (1997-1998) to 25 in the 106th Congress (1999-2000), to over 80 in the 107th Congress (2001-2002). Forty-five such legislative proposals have been introduced to date in the 108th Congress (2003-2004), as are delineated below. [124]

There appears to be growing interest in certain legislative proposals, including measures to require the reporting and disclosure of greenhouse gas (GHG) emissions, protect companies reducing GHG emissions from being penalized under a future GHG reduction program, and promote carbon sequestration. In the Senate, the **McCain-Lieberman Climate Stewardship Act of 2003** proposed capping GHG emissions of the electricity, manufacturing, commercial and transportation sectors of the economy (representing 85% of U.S. emissions) at their 2000 level by 2010 and their 1990 level by 2016. Emitters would be able to trade GHG emissions credits and get credit for pre-enactment GHG reductions, carbon sequestration, and international GHG reductions, up to a limit. The bill lost by a vote of 55 to 43, but Senator McCain has vowed to continue pushing this legislation. In March 2004, 20 members of the House (10 Republicans and 10 Democrats) introduced **Gilchrest-Olver Climate Stewardship Act of 2004** that echoes language of the McCain-Lieberman bill. It would require U.S. industries to reduce emissions of six primary GHGs from four sectors to 2000 levels by 2010.

In addition two bills and several amendments were introduced to set up green house gas registries. **The National Greenhouse Gas Emissions Inventory and Registry Act of 2003** was introduced in both the House and Senate, which would require large GHG emitters to report and disclose their emissions. Entities could also register their GHG reductions. **The Energy Policy Act of 2003**, which won approval by a vote of 84-14 in the Senate, includes three climate change titles. Title XI would establish a National Greenhouse Gas Registry and allow entities to report voluntarily their GHG emissions and emission reductions to the registry. If, five years after enactment, less than 60% of U.S. anthropogenic GHG emissions had been reported voluntarily, reporting would be required of large GHG emitters. The title also would encourage future Congresses to consider registered reductions as applicable towards future GHG reduction requirements. The bill would establish a National Climate Change Strategy with goals of 1) stabilizing

[124] World watch, http://www.worldwatch.org/features/climate/activities/#1

GHG concentrations in the atmosphere; 2) establishing an Office of National Climate Change Policy within the White House; and 3) a research and development program with a goal to stabilize GHG concentrations. A similar bill must is awaiting passage in the House.

The 45 bills, resolutions, and amendments specifically addressing global climate change and GHG emissions introduced to date in the 108th Congress are listed here:

Greenhouse Gas Reduction

S.17: The Global Climate Security Act of 2003, includes several climate change measures, including a provision establishing a commission to review measures necessary to prevent a doubling of GHG concentrations in the atmosphere, a provision to require large emitters to report and disclose their GHG emissions (see S.194), and a resolution urging U.S. participation in international climate change negotiations (see S.925 under "International Negotiations"). Sponsor: **Sen. Thomas A. Daschle** (D-SD) (17 cosponsors)

S.139: McCain-Lieberman Climate Stewardship Act of 2003, would cap the GHG emissions of the electricity, manufacturing, commercial and transportation sectors of the economy (representing 85% of U.S. emissions) at their 2000 level by 2010 and their 1990 level by 2016. Emitters would be able to trade GHG emissions credits and get credit for pre-enactment GHG reductions, carbon sequestration, and international GHG reductions, up to a limit. The 2003 bill lost by a vote of 55 to 43, but Senator McCain has vowed to continue pushing this legislation until the Senate passes it.
Sponsor: **Sen. Joseph Lieberman** (D-CT) (6 cosponsors)

H.R. 4067 Gilchrest-Oliver Climate Stewardship Act of 2004 – In March 2004, 20 members of the House (10 Republicans and 10 Democrats) introduced a bill that echoes language of the McCain-Lieberman bill. It would require U.S. industries to reduce emissions of six primary GHGs from four sectors to 2000 levels by 2010.

Global Warming Amendment to the Energy Policy Act (H.R.6) offered during markup in the House Energy and Commerce Committee, which would require the President, using existing authority, to establish a voluntary program to reduce the carbon intensity of the United States by 18% by 2012 (as announced by President Bush). (See H.R.6 E.H. under "Energy Policy."). Sponsor: **Rep. Henry A. Waxman** (D-CA) – **Action**: 4/2/03: Not accepted by the House Energy and Commerce Committee by voice vote.

Greenhouse Gas Reporting

S.194: The National Greenhouse Gas Emissions Inventory and Registry Act of 2003, which would require large GHG emitters to report and disclose their emissions. Entities could also register their GHG reductions. (See S.17 under "Greenhouse Gas Reduction.")
Sponsor: **Sen. Jon Corzine** (D-NJ) (2 cosponsors)

Energy and Climate Change Amendment to the Energy Policy Act (S.14) filed during markup in the Senate Energy Committee, which would require large GHG emitters to report and disclose their emissions and register their GHG reductions. The amendment would establish a National Climate Change Strategy, a White House Director of Climate Change Policy, an Office of Climate Change Policy at the Department of Energy, and a Forest Carbon Program at the Department of Agriculture. (See S.14 and H.R.6 E.A.S. under "Energy Policy.")
Sponsor: **Sen. Jeff Bingaman** (D-NM) – **Action**: 4/29/03 The amendment was filed but not offered during markup.

H.R.1245: **The National Greenhouse Gas Emissions Inventory Act of 2003**, which would require large GHG emitters to report and disclose their emissions. Entities could also register their GHG reductions.
Sponsor: **Rep. John W. Olver** (D-MA) (49 cosponsors)

National Greenhouse Gas Emissions Inventory Amendment to the Energy Policy Act (H.R.6) filed during markup in the House Energy and Commerce Committee, would require large emitters of GHGs to report and disclose their emissions and allow entities to register their GHG reductions (language identical to H.R.1245). (See H.R.6 E.H. under "Energy Policy.")
Sponsor: **Rep. Diana L. DeGette** (D-CO) – **Action**: 4/2/03 The amendment was filed but not offered during markup.

(See also H.R.6 E.A.S. under "Energy Policy," and S.17 under "Greenhouse Gas Reduction.")

International Negotiations

Sense of Congress on Climate Change Amendment to the Energy Policy Act (H.R.6) offered during markup in the House Energy and Commerce Committee, urges the U.S. to participate in international negotiations with the objective of securing U.S. participation in a future binding climate change treaty. (See H.R.6 E.H. under "Energy Policy.")
Sponsor: **Rep. Henry A. Waxman** (D-CA) – **Action**: 4/2/03: Not accepted by the House Energy and Commerce Committee by a vote of 18 – 34. 4/9/03: Rep. Waxman filed the amendment with the intent of offering it during debate on H.R.6 on the House floor, but was not allowed to bring it to a vote.

S.925: **The Foreign Relations Authorization Act, Fiscal Year 2004**, among other things, includes a Sense of the Congress Resolution urging the U.S. to participate in international negotiations, with the objective of securing U.S. participation in a future binding climate change treaty.
Sponsor: **Sen. Richard G. Lugar** (R-IN) – **Action**: 4/9/03: During markup in the Senate Foreign Relations Committee, **Sen. Joe Biden** (D-DE) and **Sen. John F. Kerry** (D-MA) offered the climate change resolution as an amendment, and it was accepted by voice vote. The bill was then reported out of committee by a vote of 19 – 0. The bill has been debated but not passed by the full Senate.

H.R.1950: **The Foreign Relations Authorization Act, Fiscal Year 2004**, as reported by the House International Relations Committee, included a Sense of the Congress Resolution urging the U.S. to participate in international negotiations, with the objective of securing U.S. participation in a future binding climate change treaty.
Sponsor: **Rep. Henry J. Hyde** (R-IL) (2 cosponsors) – **Action**: 5/2/03: During markup in the House International Relations Committee, the climate change resolution was offered as an amendment by **Rep. Robert Menendez** (D-NJ) and accepted by a vote of 21 – 18. 7/9/03: During markup in the House Energy and Commerce Committee, the climate change resolution was struck by a vote of 28 – 17.

(See also S.17 under "Greenhouse Gas Reduction" and H.R.6 E.A.S. under "Energy Policy.")

Energy Policy

H.R.6 E.A.S.: **The Energy Policy Act of 2003 as passed by the Senate**, is identical to H.R.4 E.A.S. in 2002, the Senate-passed Energy Policy Act of 2002. The bill includes three climate change titles. Title XI would establish a National Greenhouse Gas Registry and allow entities to report voluntarily their GHG emissions and emission reductions to the registry. If, five years after enactment, less than 60% of U.S. anthropogenic GHG emissions had been reported voluntarily, reporting would be required of large GHG emitters. The title also would encourage future Congresses to consider registered reductions as applicable towards future GHG reduction requirements. Title X would establish a National Climate Change Strategy with the goal of stabilization of GHG concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system; an Office of National Climate Change Policy within the White House; and a research and development program with a goal of stabilization of GHG concentrations. Title X also includes a Sense of the Congress Resolution urging the U.S. to participate in international negotiations, to secure U.S. participation in a future binding climate change treaty. Title XIII would authorize various climate change research activities. (See Energy and Climate Change Amendment under "Greenhouse Gas Reporting.")
Sponsor: **W.J. "Billy" Tauzin** (R-LA) – **Action**: 7/31/03: Passed by the Senate by a vote of 84 – 14, in lieu of S.14 (see below).

H.R.6 E.H.: **The Energy Policy Act of 2003 as passed by the House**, among other things, would direct the Department of Energy to research technologies for ultra-deepwater and unconventional natural gas and other petroleum resource exploration and production, including for the reduction of GHG emissions and sequestration of carbon. The bill would also establish a research program in genetics, protein science, and computational biology of microbes and plants, one goal of which would be to develop technologies and methods based on the biological functions of microbes and plants to convert carbon dioxide to organic carbon. The bill would authorize carbon capture and sequestration research and development. (See H.R.1213 under "Clean Coal," H.R.238 and H.R.1645 under "Carbon Sequestration, Genomes," the Global Warming Amendment under "Greenhouse Gas Reduction," the Sense of Congress on Climate

Change Amendment under "International Negotiations," and the National Greenhouse Gas Emissions Inventory Amendment under "Greenhouse Gas Reporting.")
Sponsor: **W.J. "Billy" Tauzin** (R-LA) (4 cosponsors) – **Action**: 4/11/2003: Passed by the House by a vote of 247 – 175.

H.R.318: **The Biofuels Air Quality Act**, among other things, would require consideration under the congestion mitigation and air quality improvement program of the extent to which a proposed project or program reduces atmospheric carbon emissions.
Sponsor: **Rep. John M. Shimkus** (R-IL) (15 cosponsors)

H.R.1644: **The Energy Policy Act of 2003**, would authorize clean coal research relating to the separation and capture of carbon dioxide. (See H.R.6 E.H.)
Sponsor: Rep. Joe Barton (R-TX) – Action: 4/10/03: Incorporated into H.R.6 E.H.

S.14: The Energy Policy Act of 2003, would establish a Hydrogen Fuel Initiative directing research into the production of hydrogen from fossil fuels, in conjunction with carbon capture and sequestration. The bill would authorize Clean Coal Power Initiative funding for projects that include the separation and capture of carbon dioxide. The bill would also establish a Genomes to Life Program, one long-term goal of which would be the advancement of science and technology regarding the conversion of carbon dioxide to organic carbon. (See S.582 and S.727 under "Clean Coal," and S.682 under "Carbon Sequestration, Genomes.")
Sponsor: **Sen. Pete V. Domenici** (R-NM) – **Action**: 4/30/03: Reported out of the Senate Energy Committee. The bill was debated on the Senate floor, but not passed by the Senate. H.R.6 E.A.S. (see above) was passed instead.

Appropriations

H.J.RES.2: **The Consolidated Appropriations Resolution 2003** provides $175 million to support policies and programs in developing countries and countries in transition that directly: (1) promote energy conservation, energy efficiency and clean energy; (2) measure, monitor, and reduce GHG emissions; (3) increase carbon sequestration activities; and (4) enhance climate change mitigation and adaptation programs. Also, the President must submit a report to the Appropriations Committees on federal agency obligations and expenditures, domestic and international, for climate change and technology transfer programs in fiscal year 2003. Also provides that funds may be used to support tropical forestry and biodiversity conservation activities and energy programs aimed at reducing GHG emissions.
Sponsor: **Rep. C.W. "Bill" Young** (R-FL) – **Action**: 2/20/2003: Became Public Law No: 108-7.

H.R.2800: **The Foreign Operations, Export Financing, and Related Programs Appropriations Act, 2004** would allow appropriated funds to support tropical forestry and biodiversity conservation activities and energy programs aimed at reducing GHG emissions. (See S.1426.)
Sponsor: **Rep. Jim Kolbe** (R-AZ) – **Action**: 7/24/03 Passed by the House by a vote of 370 - 50

S.1426: **The Foreign Operations, Export Financing, and Related Programs Appropriations Act of 2004** would appropriate $5.6 million for the Intergovernmental Panel on Climate Change/United Nations Framework Convention on Climate Change, and $185 million to support policies and programs in developing countries and countries in transition that, among other things, would measure, monitor, and reduce GHG emissions, increase carbon sequestration activities and enhance climate change mitigation and adaptation programs. Also, the bill would allow appropriated funds to support tropical forestry and biodiversity conservation activities and energy programs aimed at reducing GHG emissions. In addition, the bill would require the President to report on all Federal agency obligations and expenditures for climate change programs and activities in fiscal year 2004; as well as fiscal years 2003 and 2004 obligations and estimated expenditures, and fiscal year 2005 requested funds by the United States Agency for International Development for a variety of climate change activities. (See H.R.2800.)
Sponsor: **Sen. Mitch McConnell**, (R-KY) – **Action**: 7/17/03: Reported out of the Senate Appropriations Committee.

Power Plants

S.366: **The Clean Power Act of 2003**, would require reductions of CO_2, as well as SO_2, NO_X, and mercury emissions, from electric power plants. CO_2 emissions would be reduced to 1990 levels by 2009. (See H.R.2042.)
Sponsor: **Sen. James M. Jeffords** (I-VT) (19 cosponsors)

S.485: **The Clear Skies Act of 2003**, would require reductions of power plant emissions of SO_2, NO_X, and mercury, but not CO_2, and would exempt new power plants from the current requirement that they disclose their CO_2 emissions. (See H.R.999.)
Sponsor: **Sen. James M. Inhofe** (R-OK) (1 cosponsor) Introduced at the request of the Administration.

S.843: **The Clean Air Planning Act of 2003**, would require reductions of CO_2, as well as SO_2, NO_X, and mercury emissions, from electric power plants. CO_2 emissions would be reduced to 2006 levels by 2009 and to 2001 levels by 2013.
Sponsor: **Sen. Thomas R. Carper** (D-DE) (3 cosponsors)

H.R.999: **The Clear Skies Act of 2003** would require reductions of power plant emissions of SO_2, NO_X, and mercury, but not CO_2, and would exempt new power plants from the current requirement that they disclose their CO_2 emissions. (See S.485.)
Sponsor: **Rep. Joe Barton** (R-TX) (1 cosponsor) Introduced at the request of the Administration.

H.R.2042: **The Clean Smokestacks Act of 2003** would require reductions of CO_2, as well as SO_2, NO_X, and mercury emissions, from electric power plants. CO_2 emissions would be reduced to 1990 levels by 2009. (See S.366.)
Sponsor: **Rep. Henry A. Waxman** (D-CA) (86 cosponsors)

Transportation

S.788: The Second Century of Flight Act would direct the Federal Aviation Administration to research emerging aircraft technologies to minimize the effects on climate change, and would direct NASA to research technologies enabling commercial aircraft to reduce carbon dioxide emissions. (See H.R.2271.)
Sponsor: **Sen. Ernest F. Hollings** (D-SC) (7 cosponsors)

S.824: The Aviation Administration FY2004-2006 Authorizations Act would develop a research and implementation plan for the application of emerging aircraft technologies that would minimize the effects on climate change per unit of production of thrust and flight speed. (See H.R.2115.)
Sponsor: **Sen. John McCain** (R-AZ) (3 cosponsors) – **Action**: 6/12/03: The Senate incorporated this measure in H.R.2115 as an amendment, which passed the Senate by a vote of 94 – 0. 7/25/03: Conference report on H.R.2115 filed.

S.1072: Safe, Accountable, Flexible, and Efficient Transportation Equity Act of 2003 would establish a multimodal energy and climate change program to study the relationship of energy, transportation, and climate change, and call for the development of strategies to reduce GHG emissions from transportation. (See H.R. 2088)
Sponsor: **Sen. James Inhofe** (R-OK) (3 cosponsors) Introduced at the request of the Administration.

H.R.2088: The Safe, Accountable, Flexible, and Efficient Transportation Equity Act of 2003, which, among other things, would establish a multimodal energy and climate change program to study the relationship of energy, transportation, and climate change, and call for the development of strategies to reduce GHG emissions from transportation. (See S.1072)
Sponsor: **Rep. Don Young** (R-AK) (3 cosponsors) Introduced at the request of the Administration.

H.R.2115: The Aviation Administration FY2004-2006 Authorizations Act as in the conference report, which, among other things, would develop a research and implementation plan for the application of emerging aircraft technologies that would minimize the effects on climate change per unit of production of thrust and flight speed. (See S.824. The House-passed version of H.R.2115 did not include the climate change-related provision.)
Sponsor: **Rep. Don Young** (R-AK) (3 cosponsors) – **Action**: 7/24/03 Conference held. 7/25/03 Conference report filed.

H.R.2271: The Second Century of Flight Act would require the Federal Aviation Administration to develop a research plan for emerging technologies that minimize the effects on climate change per unit of production of thrust and flight speed; and require NASA to develop a research plan to enable commercial aircraft to significantly reduce CO_2 emissions. (See S.788.)
Sponsor: **Rep. Todd Tiarht** (R-KS) (1 cosponsor)

Hydrogen

S.821: **The Hydrogen and Fuel Cell Energy Act of 2003** would seek to reduce the life cycle pollution and GHG emissions from energy use by promoting, e.g., hydrogen R&D, federal purchasing of stationary fuel cells, and tax incentives for hydrogen and fuel cell vehicles and related infrastructure.
Sponsor: **Sen. Tom Harkin** (D-IA)

H.R.1299: **The Hydrogen Fuel Act of 2003**, includes a finding that it is in the national interest to support the development of a light duty vehicle fleet that is free or near free of GHG emissions.
Sponsor: **Rep. Sherwood Boehlert** (R-NY)

H.R.1395: To provide for the establishment of research, development, demonstration, and commercial application programs for fuel cell and hydrogen production, delivery, and storage technologies for transportation and stationary applications. The bill would require the Department of Energy, to award projects for hydrogen production and capture of associated carbon dioxide.
Sponsor: **Rep. John B. Larson** (D-CT)

H.R. 1777: A bill to provide for the establishment at the Department of Energy of a program for hydrogen fuel cell vehicles and infrastructure. The bill would require DOE to address the production of hydrogen from fossil fuels, which may include carbon capture and sequestration.
Sponsor: **Rep. Sherwood Boehlert** (R-NY)

Clean Coal

S.582: The Coal Energy Research Development and Demonstration Act of 2003, would authorize carbon capture and sequestration research and development, and provide tax credits for advanced clean coal technology units that meet certain carbon emission rate standards. (See S.14 under "Energy Policy.")
Sponsor: **Sen. Jim Bunning** (R-KY) (8 cosponsors)

S.727: **The National Coal Research, Development, and Demonstration Act of 2003** would authorize carbon capture and sequestration research and development, and provide tax credits for advanced clean coal technology units that meet certain carbon emission rate standards. (See S.14 under "Energy Policy.")
Sponsor: **Sen. Robert C. Byrd** (D-WV) (13 cosponsors)

S.1149: **The Energy Tax Incentives Act of 2003** would provide tax credits for advanced clean coal technology units that meet certain carbon emission rate standards.
Sponsor: **Sen. Charles E. Grassley** (R-IA) – **Action**: 5/23/03: Reported by the Senate Finance Committee.

H.R.1213: **The Clean Coal Power Act of 2003** would authorize carbon capture and sequestration research and development, and provide tax credits for advanced clean coal

technology units that meet certain carbon emission rate standards. (See H.R.6 E.H. under "Energy Policy.")
Sponsor: **Rep. Ed Whitfield** (R-KY) (18 cosponsors)
H.R.1269: **The Coal Energy Research, Development, and Demonstration Act of 2003** would authorize carbon capture and sequestration research and development.
Sponsor: **Rep. Jerry F. Costello** (D-IL) (5 cosponsors)

Carbon Sequestration, Genomes

S.682: **The Genomes to Life Research and Development Act** would establish a research and development program in systems biology and proteomics (a proteome is a protein complement to a genome), one long-term goal of which would be to stabilize atmospheric levels of carbon dioxide to counter global warming, and one specific goal of which would be to understand the Earth's natural carbon cycle and to create strategies to stabilize atmospheric carbon dioxide. (See S.14 under "Energy Policy.")
Sponsor: **Sen. Pete V. Domenici** (R-NM) (3 cosponsors)

H.R.238: **The Energy Research, Development, Demonstration, and Commercial Application Act of 2003** would direct the Department of Energy to research technologies for ultra-deepwater and unconventional natural gas and other petroleum resource exploration and production, including for the reduction of GHG emissions and sequestration of carbon. (See H.R.6 E.H. under "Energy Policy.")
Sponsor: **Rep. Sherwood L. Boehlert** (R-NY) (1 cosponsor) – **Action**: 5/22/03 Reported out of the House Science Committee

H.R.1645: To establish a research, development, and demonstration program in genetics, protein science, and computational biology of microbes and plants to support the energy and environmental mission of the Department of Energy. One goal of the program would be to develop technologies and methods based on the biological functions of microbes and plants to convert carbon dioxide to organic carbon. (See H.R.6 E.H. under "Energy Policy.")
Sponsor: **Rep. Sherwood Boehlert** (R-NY)

H.R.1904: **The Healthy Forests Restoration Act of 2003** would direct the Department of Agriculture to establish a healthy forests reserve program, one goal of which would be to enhance carbon sequestration.
Sponsor: **Rep. Scott McInnis** (R-CO) (137 cosponsors) – **Action**: 5/20/03 Passed by the House by a vote of 256 – 170.

Climate Science

S.1164: The Abrupt Climate Change Research Act of 2003 would establish within the National Oceanic and Atmospheric Administration (NOAA), a program of scientific research on abrupt climate change.
Sponsor: **Sen. Susan M. Collins**, (R-ME) (4 cosponsors)

HR 984: National Oceanic and Atmospheric Administration Act of 2003 would authorize the Commerce Department to establish joint or cooperative institutes with qualified colleges and nonprofit research organizations to collaborate on long-term climate change research.
Sponsor: **Rep. Wayne T. Gilchrest** (R-MD)

H.R.1578: The Global Change Research and Data Management Act of 2003 would promote and coordinate global change research.
Sponsor: **Rep. Mark Udall** (D-CO) - Action: 5/1/2003: The House Science Committee voted against reporting the bill by a vote of 17 - 19.

State, Regional, Local and Private

In the United States, laws to address climate change—such as mandated emissions reductions or policies to promote renewable energy—are easier to pass at the state and local levels than at the federal level, where coal, oil, and auto industry can concentrate lobbying efforts to affect such laws. In the absence of Federal laws or regulations, states, communities, and businesses are leading the way to address climate change. Several noteworthy efforts are listed below:

Regional Activities

California, Oregon, and Washington – In 2003, the governors of these states directed their staffs to draft recommendations on ways to collaborate regionally in reducing emissions in several sectors of their economies—including by using more efficient vehicles, increasing the share of renewables in electricity generation, and creating emissions accounting systems and inventories.

New England and Canada's Eastern Provinces – In 2001, governors of New England states and premiers of Canada's Eastern provinces approved a comprehensive regional Climate Action Plan that aims to reduce GHG emissions to 1990 levels by 2010.

11 Northeastern States – In spring 2003, Governor Pataki of New York invited the governors of 10 other states to participate in the development of a regional program to cap and trade CO_2 emissions. Program design for this Regional Greenhouse Gas Initiative is expected to be complete by April 2005.

Pressing for Federal Regulations – In July 2002, the attorneys general of 11 states (Alaska, California, Connecticut, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont) sent a letter to the Bush Administration pressing for strong federal measures to limit U.S. national GHG emissions.

State Legislation and Programs

The Pew Center for Global Climate change lists 28 different states with 44 state and local programs that reduce greenhouse gas emissions. Some programs were designed

specifically to address climate change, but many were designed for other purposes: for example, to improve energy efficiency or to promote water conservation. All, however, directly or indirectly result in greenhouse gas reductions. During 2003 alone, at least 24 states introduced 90 bills to build frameworks to regulate GHG emissions. One-quarter of all U.S. states have enacted Renewables Portfolio Standards (RPS), which mandate an increase in the states' share of electricity generated with renewable energy. About half of all U.S. states have established renewable energy funds to provide subsidies for installation of renewable energy projects, or for the production of renewable electricity, for energy efficiency projects, and for energy education and awareness programs.

Maine and New Jersey have set greenhouse gas reduction targets. Maine has set a statewide target for reducing greenhouse gas emissions to 1990 levels by 2010, to 10% below 1990 levels by 2020, and by as much as 75-80% over the long term. New Jersey has established a goal to reduce its greenhouse gas emissions by 3.5 percent from 1990 levels by 2005. The state draws upon voluntary agreements with public- and private-sector organizations as well as regulatory initiatives in order to reduce emissions.

Massachusetts has established a multi-pollutant cap that requires six older power plants to reduce their CO_2 emissions by ten percent relative to 1997-1999 levels by 2006 or 2008, depending on the method of compliance chosen. This represents 40 percent of the state's electricity.

Some northwest states have established programs requiring offsets in emissions for new power plant construction. In **Oregon**, the Climate Trust is a nonprofit organization that funds development of projects that counter 17 percent of new power plant CO_2 emissions. This can be done through improvements in energy efficiency of buildings, investments in renewable energy, reforestation, and other types of projects that result in emissions reductions or carbon sequestration. **Washington** as recently as June 2004 began requiring new power plants planned in the state to offset or mitigate 20 percent of their expected carbon dioxide emissions. Companies can comply with the new law by undertaking mitigation efforts such as planting trees (which sequester carbon dioxide), retrofitting diesel buses with cleaner-burning fuel, or investing in energy conservation. Alternatively, companies can pay third parties approved by the state at a rate of $1.60 for each metric ton of carbon per 30 years to undertake mitigation activities. Third parties must submit reports to the state and allow their mitigation efforts to be inspected and audited by the state.

City and Community Efforts and Commitments:

In October 2003, 155 mayors, representing more than 46 million people, issued a statement calling on the Federal government to join them in efforts to reduce the threat of climate change. (See www.iclei.org/us/mayors_statement/) The statement notes that "Global warming poses significant threats to communities across the country. We are already feeling impacts in the form of heat waves, shrinking water supplies and snow pack, increased rates of asthma, floods and storms, and coastal erosion. This issue requires an effective response from the U.S. Federal Government." The statement also

notes the economic, health and security benefits of reducing emissions through conservation, efficiency, and the use of cleaner, more sustainable technologies. Signatories include mayors of **Atlanta, Boston, Boulder, Dallas, Honolulu, Houston, Louisville, Las Vegas, Minneapolis, Newark, New Haven, Sacramento, and San Diego**. Throughout North America, 249 cities (most in the U.S.) have joined Cities for Climate Protection, a program of the International Council for Local Environmental Initiatives that commits them to inventory and create detailed action plans for reducing their GHG emissions. As of April 2004, 579 cities worldwide had joined this effort.

Private and Corporate Targets and Achievements:

Many companies have taken initiative to voluntarily set targets for greenhouse gas emissions. See the details below:

Dupont – Has already achieved its target of reducing GHG emissions 65 percent below 1990 levels; the original target date was 2010. Dupont plans to derive 10 percent of the energy it uses worldwide from renewable sources by 2010.

Silicon Valley – Hewlett-Packard, Oracle, Calpine, Lockheed, ALZA, Life Scan, and PG&E announced in March 2004 a plan to reduce CO_2 emissions in Santa Clara County, California, to 20 percent below 1990 levels by 2010. This is triple the goal that the Kyoto Protocol set for the United States as a whole (a 7 percent reduction below total U.S. 1990 emissions levels by 2012). Companies plan to curb their emissions by retrofitting buildings with more efficient heating and cooling systems and insulation; shifting auto fleets to hybrid vehicles; replacing light bulbs with compact fluorescent bulbs; and installing motion detectors. They expect all of these changes to be cost-effective. The city of San Jose will also take part, improving public transportation, enacting more energy efficient building codes, and converting its vehicle fleet to hybrids.

Alcoa – Has committed to reducing its GHG emissions to 20 percent below 1990 levels by 2010.

Bank of America – In May 2004, the corporation announced unprecedented targets and timetables for reducing its greenhouse gas emissions, with an initial goal to reduce emissions 7 percent by 2008, and pledged to stop funding projects that involve oil and gas exploration, among other things.

Power Companies

Five U.S. power companies committed in early 2004 to reducing their GHG emissions and to supporting a mandatory federal cap on CO_2 emissions. As part of the **PowerSwitch Challenge** initiated by the World Wildlife Fund, **Austin Energy (Texas), Burlington Electric Department (Vermont), FPL Group (Florida), Sacramento Municipal Utility District (California), and Waverly Light and Power (Iowa)** have committed to undertaking at least one of the following by 2020: increasing the share of electricity they sell that is generated by renewables to 20 percent; increasing energy

efficiency by 15 percent; and/or retiring the least-efficient half of their coal generating capacity.

Shaw's Supermarket – Now sells renewable electricity in several New England cities, and at least 3 of its stores are purchasing renewable energy to meet 25 percent of their electricity needs. Shaw's was the first supermarket chain in New England to offer green power to its customers. The renewable energy is generated on the rooftops of BJ's Wholesale Club stores.

Green Power – An estimated 10,000 U.S. businesses (and 110,000 households) are now using certified "green" electricity that is generated with renewable resources.

APPENDIX C *DRAFT PLAN FOR A NORTH CAROLINA CLIMATE ACTION REGISTRY*

This plan has been developed by the North Carolina Department of Environment and Natural Resources (DENR), Division of Air Quality (DAQ) with input and views from the DENR Division of Pollution Prevention and Environmental Assistance (DPPEA), the State Energy Office (NCSEO) and many others such as stakeholders, national forums, federal agency information and various internal and external information sources. This draft is provided as a "straw man" to stimulate discussion. It is not provided as a recommended plan at this time. However, since there has been substantial discussion of such a registry in the State for the past few years, this draft proposal is included here for further information and generation of ideas and reactions as to what the best options to proceed might be at such a time as it is deemed necessary.

Background

Summary of NC and Federal Historical Activities

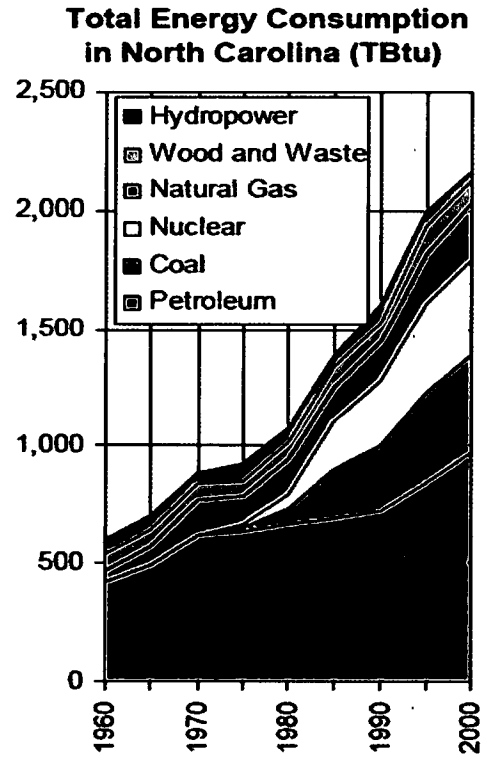
North Carolina does not have, and has never had, a stand-alone registry for GHG emissions. However, the state, through various venues has participated in many related or complementary activities over the past decade. This summary is intended to provide the essence of some of the historical and ongoing efforts that have occurred, and how they relate to today's situation and underlying thoughts on approaches to take and why. This discussion is not intended to be inclusive of all background and actions, but primarily those that relate to the development of North Carolina's plans for the future.

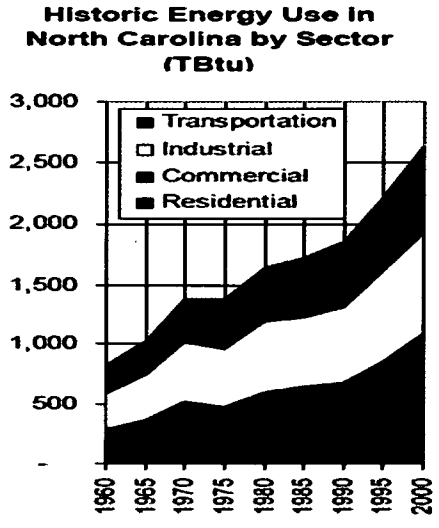
Registry of GHG's alone is not a productive end product, but could readily provide an integral tool, and be part of a larger process, to actually help generate reductions in GHG emissions. For a program to be viable to support trading, sale, etc., it must provide mechanisms for universal participation, consistent accountability among the emitters and the registration process. It must maintain a method for verification of emissions and be credible on national and international exchanges so that the "currency" is validated and interchangeable with that in other jurisdictions. In addition, the process must assure that companies or other entities are required to show all their releases, not just for those situations and jurisdictions where the results will appear more favorable to their position. It should be clearly understood at the outset that coal-fired utilities are already, in fact, reporting to the National Acid Rain Program, annually, and using continuous emission monitors (CEMs) for their CO_2 emissions, which are much more accurate and provide more complete and verified data than for other fuel combustion facilities, or other generators of GHG. In addition, generally these facilities voluntarily participate in the DOE 1605 (b) voluntary registry and any registry developed should reflect the availability of these verified and accurate data and not "re-invent this wheel." Any North Carolina Climate Change Registry should focus on other (to include "all") sources in the State, as discussed in the next section. The reader is reminded here also, of the

distinction between the GHG and CO_2, the latter of which is the literal subject of the CSA requirement.

Sources and Emissions in North Carolina

The figures below from the North Carolina SEP present a graphic view of the distribution of fuel consumption in the state. The combustion of fuel is not the only source of GHG's but is a substantial portion and for many purposes may be considered the same. Note that the predominant source of CO_2 in the State is from Petroleum fuels, which includes automobiles, trucks, trains, planes, construction equipment and various other forms of power generation. Note also that growth has been fairly consistently in all areas, but the predominant largest sector has been residential, followed by industrial. These factors need to be considered in the development of a system of registry such that the entire source population is included and that the "efforts" for the registry are productive and fruitful in comparison with the efforts and expenses involved.

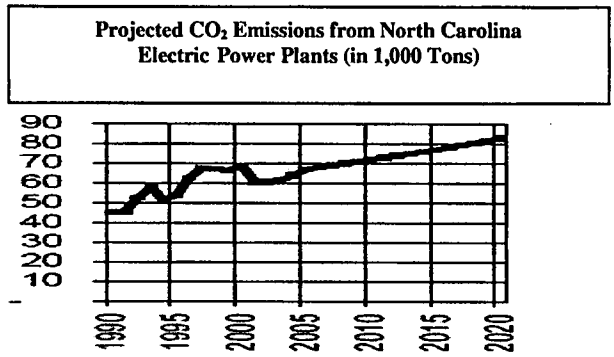




The largest single sector in terms of total energy use (including the energy consumed to generate electricity for the sector) is industrial at 31% of the total. Transportation is second largest with 28% of total energy use. The residential (23%) and commercial (18%) sectors, if combined, would demonstrate that the largest energy use in the state is in buildings at 41%.

125

125 North Carolina State Energy Plan, June, 2003, http://www.energync.net/State%20Energy%20Plan%2003.pdf



126

The discussion above is not intended to suggest that the coal fired power plants in the State are of trivial impact on the State's CO_2 or GHG emissions "burden." Approximately one third of the annual CO_2 in the state comes from the generation of electric power, and as the figure above indicates, that contribution is not expected to decrease, without some decisive actions to reduce (efficiency or reduction programs) or to substitute other sources of electricity for that generation capacity.

U.S. DOE and U.S. EPA Registries and Related Programs

GHG efforts at the federal level have been primarily under the auspices of the DOE and the EPA. A brief reflection of what prior efforts have been, and what is currently being done nationally/globally, are provided here as a backdrop for information on North Carolina's past and likely or proposed future roles.

US DOE 1605 (b)

The DOE, acting under the requirements of the Energy Policy Act of 1992[127], established the *National Inventory and Voluntary Reporting of Greenhouse Gases*, also known as the 1605 (b) Registry. This mechanism provides a means for facilities to voluntarily report their emissions and/or reductions in emissions of GHGs to a centralized national repository. NC facilities have a relatively good record of reporting and listing in this registry. NC has consistently been a national leader with participation of up to 39 facilities (generally assisted in NC by the DOE-funded pilot 'Climate Wise' program, which has since lost this federal funding support). The 1605 (b) Registry has been operating since about 1994 and continues as the primary repository of reported GHG emissions and reductions data for the US, even though it does not meet many of the desired criterion for its ultimate success.

On November 26, 2003, DOE released proposed revised General Guidelines for the voluntary reporting of greenhouse gas emissions and emission reductions under this program.[128] DOE accepted comments through February 17, 2004. DAQ and State Energy Office (SEO) staff attended the DOE's public workshop on these proposals of the policy guideline revisions and submitted formal comments. DOE has also expressed

---

[126] North Carolina State Energy Plan, June, 2003, http://www.energync.net/State%20Energy%20Plan%2003.pdf

[127] Section 1605(b) of the Energy Policy Act of 1992 (EPACT), 42 U.S.C.13385(b)

[128] Department of Energy, 10 CFR Part 300, General Guidelines for Voluntary Greenhouse Gas Reporting, http://www.pi.energy.gov/pdf/library/Formatted1605%28b%29GeneralGuidelinesfinal.pdf

intention to make further revisions to the proposed *General Guidelines* available for public comment, simultaneously with the issuance of proposed *Technical Guidelines* during "the late spring or early summer of 2004." To date, these proposals have not been released. NC DAQ expects to comment on these technical proposals whenever they are released. The 1605 (b) program remains a most viable repository for North Carolina GHG data. However, for this information to be useful and credible on a National/International accounting and/or trading basis, parallel technical procedures that are uniform and accepted must be developed and adopted and the reporting by all major emitters must become mandatory.

US EPA Climate Leaders

Climate Leaders[129] is a voluntary industry- government (EPA) partnership initiated in February 2002[130] at EPA, that encourages companies to develop specific long-term comprehensive climate change strategies and set (GHG) emissions reduction goals. One part of this program is GHG registration. However, there is no direct link to the DOE 1605 (b) Registry and data submittal from one agency/registry to the other is not required or automatic. This does not encourage companies to participate in multiple programs and will not likely result in their efforts being interchangeable. Several companies with operations or facilities in NC have opted to participate in this program.

The partners listed below (Spring 2004), were compiled from the EPA web page:
3M, Advanced Micro Devices, Inc., American Electric Power, Baxter International, Cinergy Corp, Eastman Kodak Company, FPL Group, Inc., General Motors Corporation, Holcim (US) Inc., IBM Corporation, Interface, Inc., International Paper, Johnson & Johnson, Miller Brewing Company, National Renewable Energy Laboratory, Norm Thompson Outfitters, Inc., Pfizer, Inc., PSEG, S.C. Johnson & Son, Inc., St. Lawrence Cement, and United Technologies Corporation.

Only a limited number (21) of the possible thousands of companies in the US had committed to this voluntary program at that time. However, the companies participating represent many large individual and collective operations. Without mandatory reporting and clearly established reduction goals, the benefit of this effort as a national or international registry is limited. As a minimum, it should feed data automatically to the DOE1605 (b) registry.

EPA's Acid Rain Reporting

The overall goal of the Acid Rain Program, as established by the Clean Air Act Amendments of 1990, is to "achieve significant environmental and public health benefits through reductions in emissions of sulfur dioxide (SO_2) and nitrogen oxides (NOx), the primary causes of acid rain." To achieve this goal at the lowest cost to society, the program employs both traditional and innovative, market-based approaches for controlling air pollution. In addition, the program has elements to encourages energy efficiency and pollution prevention.

---

[129] USEPA, Climate Leaders, http://www.epa.gov/climateleaders/

[130] EPA Administrator Launches Climate Leaders Program Charter Members Commit to Greenhouse Gas Inventories and Emissions Reduction Targets (2/20/2002)

Under the Acid Rain Program, each utility unit must continuously measure and record its emissions of SO_2, NOx, and CO_2, as well as volumetric flow and opacity. In most cases, a continuous emission monitoring (CEM) system is required. There are provisions for initial equipment certification procedures, periodic quality assurance and quality control procedures, recordkeeping and reporting, and procedures for filling in missing data periods. Units report hourly emissions data to EPA on a quarterly basis.

Phase I of the NOx program began on January 1, 1996 and has continued to expand and improve since. Data reported are recorded in the Emissions Tracking System, which serves as a repository of emissions data for the entire utility industry, for major boilers and boiler types, but not some peaking (e.g. internal combustion turbine) operations. There is no automatic link or data transfer mechanism currently established (or plans for such known) that results in the CO_2 (utilities/combustion emissions are limited primarily to CO_2 and not some of the other GHGs) data reported via this program to be automatically translated to the DOE 1605 (b) or other central registry. Many utilities (including NC utilities) however, do participate in the 1605 (b) Registry by "re-reporting" their emissions and/or emission reduction efforts to that registry, even though it is not required. Even then, this reporting may not be carried out consistently and with the same purpose or data presented for facility-wide and company-wide emissions.

Climate Wise in NC

As mentioned above, the Climate Wise program operated in NC for several years (with DOE funding) as a pilot program to initiate and support reporting to the DOE 1605 (b) Registry. After funding support from DOE expired, the state budget did not support the program. Thus, it ceased to be effective. However, a non-profit (501 c-3) company, *Global Warming Initiatives, INC*, was formed to search for private funding and to carry on the efforts to assist former registrants and potential new participants. That company continues to assist former participants in Climate Wise and others who are interested. However, dependable funding is lacking and it is dependant upon grants and donations from the participating companies. The future of this effort may well depend upon the infusion of additional public and private grant or other funds to continue the assistance and consultation.

Climate Leaders in NC

As identified above, several companies in North Carolina participate in EPA's Climate Leaders program. However, those that have participated have done so directly with EPA without significant input or support from NC agencies. This is the manner in which the program is likely to continue unless a specific agency in NC is identified and funded with the purpose of supporting and assisting this program. This program may identify specific interested facilities within the state, but does not necessarily result in emissions or reductions being reported to any centralized national and internationally accepted database as is necessary for a viable program with real reductions to global totals of GHG emissions.

Climate Vision in NC

In 2003, the federal government and industry organizations representing thousands of companies from 12 energy-intensive economic sectors joined in a voluntary partnership called Climate VISION. Those economic sectors include automobile manufacturers, chemical manufacturers, railroads, the oil and gas industry, the electric power industry, the mining industry, and the cement, iron and steel, aluminum, magnesium, semiconductors, and forest products industries. Joining in this presidential initiative were DOE, DOT, DOA and EPA. Climate VISION works with industry to identify and pursue cost-effective solutions to reduce emissions using existing technologies; develop tools to calculate and report emission intensity reductions; speed the commercial adoption of advanced technologies; and develop strategies to reduce emissions intensity in other economic sectors.

The electric power sector participates in the Climate VISION program through the Electric Power Industry Climate Initiative (EPICI) and its Power Partners program, which is being developed in cooperation with the Department of Energy. The memberships of the seven organizations that comprise EPICI represent 100% of the power generators in the United States. The power sector, through EPICI, plans to finalize its work plan in the form of a Memorandum of Understanding (MOU) with DOE. The MOU will outline proposed implementation actions to reduce greenhouse gas emissions intensity by 2012. The power sector, in conjunction with DOE and other federal agencies, will implement the actions. In North Carolina, Duke Energy and Progress Energy are both participating in this program through the Electric Power Research Institute (EPRI).[131]

Environmental Performance Track

EPA's *Environmental Performance Track* program is a voluntary program beyond their current requirements. A new component of the program, Challenge Commitments,[132] encourages facilities within the program to commit to regional environmental priorities as one of their performance goals. Each EPA region establishes regional environmental priorities with input from the states within the region. DENR's Division of Pollution Prevention and Environmental Assistance (DPPEA) program staff has established activities with this program which is expected to likely become more directly associated with climate change initiatives.

NC Environmental Stewardship Initiative

North Carolina's Environmental Stewardship Initiative (ESI) is a voluntary program that establishes incentives and recognizes facilities using pollution prevention and innovative approaches to meet and exceed regulatory requirements. DENR's DPPEA[133,134] manages the ESI. This program seeks to reduce the impact on the environment beyond measures required by any permit or rule, producing a better environment, conserving natural resources and resulting in long-term economic benefits. The program will educate and encourage the use of voluntary reporting of GHG.

State Energy Plan Interfaces

The State Energy Office (in the Department of Administration) is North Carolina's lead agency for energy programs and serves as the official source for energy information and assistance for consumers, businesses, government agencies, and policy makers. In addition, North Carolina's General Assembly established the Energy Policy Council in 1975 as a means of addressing state-specific energy issues and concerns. The Energy Policy Council's role is periodic examination of energy use, energy production, and environmental concerns in our state.

As State and national energy issues change, and it is deemed productive, the Council is charged with revising or producing a new State Energy Plan. For the most recent plan, the Energy Policy Council started with the formation of a working group composed of members representing key energy and environmental interests, with a charge to develop an updated energy policy and program recommendations. North Carolinians from various sectors provided input to the Energy Policy Working Group[135] and the Group then produced a new State Energy Plan in 2003.

The **State Energy Plan**[136] provides a major review and an analysis of what the energy consumption patterns are in NC and a series of recommended actions that form a 'blueprint' to assist the state to achieve its energy goals. This plan shares consistent goals of reductions of use of energy, which will assist in the reduction of CO_2 emissions, as identified for potential reductions in the CSA. These complimentary legislations provide a tandem approach to different aspects of the same problems and must be carried out in parallel. One of the stated goals of the Energy Plan is to develop a GHG or Climate Change Gases Registry. Though no specifics are given, the development of these plans are envisioned to be completed cooperatively with other departments, including the DENR and its component divisions, and is substantially consistent with the CSA's intent.

Previous NC Legislative Involvement and Analysis of Proposals

In the 2002 Session of the NC General Assembly, Bills were introduced into both Houses[137] to initiate a "voluntary" Climate Action Registry (House Bill 1045 -Short Title: NC Climate Action Registry). The Bill's introductory language directed: "The State's tradition of environmental leadership should be recognized through the establishment of a registry to provide documentation of those greenhouse gas emissions reductions that are voluntarily achieved by sources in the State."

Furthermore, the language indicated that it was to be in preparation for mandatory greenhouse gas emissions reductions that "may be imposed on North Carolina sources at some future point." In view of this, the Bill stated that, the "State has a responsibility to use its best efforts to ensure that organizations that voluntarily reduce their emissions receive appropriate consideration for emissions reductions made prior to the implementation of any mandatory programs."

---

[135] http://www.ncenergy.appstate.edu/index.php

[136] http://www.energync.net/State%20Energy%20Plan%2003.pdf

[137] http://www.ncleg.net/html2003/bills/CurrentVersion/house/hbil1045.full.html

The House Bill also stated that guidelines and the rules developed should include : programs to establish emissions baselines and to monitor and track greenhouse gas emissions, systems to verify emissions and reductions of emissions, the adoption of a uniform format for reporting emissions baselines and reductions in order to facilitate their recognition in any future regulatory scheme, and maintain a record of all emissions baselines and reductions."

This session ended without passage of any version of a **Climate Action Registry Bill**, nor were any expectations or provisions defined that would quantify the resources to be provided and the expectations of how these requirements would be fulfilled.

The draft Bills and surrounding discussions seemed to recognize that before a Climate Action Registry could become effective in achieving reductions that it had to

- Cover all sources, including all states in the US, and all countries contributing significantly to the global emissions of GHG's (or CAG's in the Bill's terminology) in order to be able to define and track the total contributions and to assure that transfer of emissions out of one area to another did not occur.

- Be mandatory, because if it is not mandatory, the total emissions and of the emissions from various sectors can not be determined.

- Be associated with a reduction goal (e.g., "xx% below the levels emitted in 1990").

- Be recognized as a database of information to serve as a "valid currency" around the world, through a process of documentation, certification and verification, such that uniform procedures were always followed and in a consistent manner.

- And, ultimately be amenable to interstate and international carbon or GWG trading programs that would allow facilities to find innovative and cost saving means to reduce their emissions in view of a global target.

These features are also consistent with the assessment of the DAQ as to what would be needed to actually achieve reductions in GHG's in North Carolina, or elsewhere.

Range of DAQ Options and Concerns/Issues for Planning a NC Registry

Overview/Introduction

Various levels of effort for development and implementation of a registry are possible. The choices however, involve resources required to implement that program, level of accuracy and transparency (documentation and public display) of information, level of quality assurance and certification, size of facility, treatment of "secondary reductions" such as consumer reductions of electric power usage, treatment of non-point sources, frequency of update and other such practical and resource-related considerations. Details and resource requirements need to be determined in consideration of what the major sources are and how they may ultimately provide for emission reductions, and the impact of costs of their control.

Basis for Program to Fit Needs/Requirements

DAQ is supportive of efforts for control/reduction of GHG and has evaluated several options and discussed several issues. These discussions have taken into account the needs and desires expressed in various NC reports and legislative efforts, national and international considerations for long term achievement of successful reductions in GHG and other practical issues such as resources to support such efforts. Some related points and facts from those discussions, both internally at DAQ and with other Divisions and Departments, are summarized below:

- It is prudent to take action to reduce GHG emissions and DAQ supports this goal.
- DAQ currently has no mandates or resources for GHG/CO_2 beyond the required reports for the Clean Smokestacks Act, and resources were not appropriated for these studies.
- The development of a registry is on the top 15 list of priorities in the NC **State Energy Plan.**
- USEPA does not currently consider CO_2 to be a "pollutant" (by their interpretation of the Clean Air Act), falling under the same procedures and processes that DAQ has historically implemented.
- CO_2 from coal-fired utilities (the largest emitting point source sector) is already continuously measured and reported to EPA (Acid Rain program from continuous measurements) and DOE (mandatory) for coal-fired power plants.
- Other fuel-burning industries are important, but not so much as the coal-fired utilities which already report.
- Other sources such as transportation (mobile on road and off road) emit about the same magnitude (as a group) as coal-fired utilities and should be included in such periodic compilation of estimates as well.

Though DAQ is supportive of a GHG/CO_2 registry, there are concerns and reservations that need resolution:

- A greenhouse gas registry by itself would not reduce Greenhouse gases (GHG) but could be a key tracking tool in an overall integrated program.
- To meet ultimate usefulness and be productive, a Climate Action registry should be coupled with reduction goals and complete coverage of sources.
- Adequate resources should be provided such that such a registry could be expected to accomplish the level of program that is desired.
- It would be difficult to establish and maintain a "limited" voluntary effort and its usefulness would be questionable.
- North Carolina governmental facilities and fleets, and programs addressing the emissions from these sectors should be included and their emissions tracked, perhaps as a pilot effort in the beginning of any such broader program.
- For a Registry to meet likely expectations and needs, it should:
  - Be widely accepted (Interchangeable in NC, Nationally and Internationally)
  - Be mandatory of the emitting sources (Currently ~3100 facilities in NC hold an air permit, with majority of them burning fuel of some sort; ~400 of these are larger Title V sources, including coal-fired power plants)

- Be coupled with other emitting sectors, in addition to NC's air permitted population
- Be used as the yardstick for gauging future mandatory reductions coupled with an action plan for the reductions and tracking (If one does not know the whole picture, it is difficult to act appropriately with a portion of the total)
- Be based on emission estimates that are complete, compatible and interchangeable with similar estimates from other jurisdictions up to and including other countries (Requiring going beyond project-level programs with state monetary investments in protocols, software and external coordination)
- Be administered by an organization that has sufficient funding and staffing/expertise to accomplish the tasks of
    - ✓ Outreach
    - ✓ Technical assistance
    - ✓ Protocol development and harmonization with other state and national or international protocols
    - ✓ Provide for third party certification
    - ✓ Enforcement against failures to comply with requirements
    - ✓ Provide automated output to National and International databases
    - ✓ Provide authority for speaking on behalf of state interests in national and international forums

Options Assessed

DAQ's assessments of options have covered a wide range; from "doing nothing" to an extensive stand alone program. For purposes of brevity, but to demonstrate some of these options evaluated, three levels are discussed briefly below before providing more detail of a recommended option. These levels originally evaluated fell into three general groups: "minimal," "intermediate," and "major stand-alone."

Minimal Effort-Low Benefit

A **minimal first step** toward a Climate Action Registry could be a simple "registration" of emissions accomplished by adding the GHG pollutants to the existing air emission inventory done in NC. This would require notification, and education of DAQ and facility staff, possible rule changes and some data processing system changes. It would take several months and require appropriation of additional resources and would not be certifiable nor necessarily follow complete and detailed protocols as would be needed to insure that the emissions identified are 'tradable' in the future, useful for baseline certification nor be necessarily compatible with various protocols used in other states, the nation or internationally. No resources are currently available for this option, though it is relatively minimal **compared to more comprehensive registry alternatives.**

Intermediate Commitment Option – Limited Benefits

Intermediate options could cover a wide range of levels and be pursued beyond the 'minimal registration' effort outlined above to a full scale certified, mandatory, state-wide inventory with automated reporting/participation with national/global efforts and registries is possible. One such intermediate scenario is outlined below, primarily to indicate the elements and their interactions. It would

- be a NC Voluntary Program
- require commitment to reductions state-wide, without teeth or ability and commitment to track all activities contributing
- actively support solicitation of voluntary participation in national efforts and
- require addition of GHG's to routine DAQ emission inventory

This level of program and support would involve industry workshops and more active or intensive information exchanges and education for a voluntary state program and continued efforts to support and promote the mandatory national efforts. In addition, the option could develop and provide a "third party" verification program in the future. The routine DAQ inventory would require modification to add GHG's. No efforts to provide a third party review, or for DAQ to have a strong role to get the data entered into the national registries would necessarily be involved in a base case, but the third party review and certification could be an add-on if/when additional needed funding were available.

Resources estimated for this level of activity would be in the range of over $100,000. per year with an additional $150,000 or more for contract support for a Third Party Validation program, if included.

Legislation Required: – Fee requirements and authorizations and/or funding appropriations would be necessary for such a program. Authority for program of collection of information may not be technically require legislation but would be supportive, especially if coupled with a state target for reductions.

Other considerations- This option would provide elementary base program with substantial effort and product to estimate and track GHG's but would not insure reductions without a state target and some mandatory requirements, both for reporting and needed reductions.

Concerns:

- Not mandatory-not oriented to success of an identified and measurable objective
- Not funded by guaranteed short or long term funding

Major Stand-alone Program – High Costs but Higher Benefits

It would be possible, with time, funding and continued support to develop a mandatory reporting for most major sub-sets of the emitting population; including tracking of all sectors of area and mobile sources, to fully provide a picture of the GHG emissions and the success of any reduction strategies. Such a program would need to be provided with or able to establish a regulatory enforceable target and authorizations to "own" public assets in a global trading environment such that funds could be raised and utilized to achieve reductions. Such a program is not fully fleshed out in this narrative. However, DAQ estimates that such an effort would require resources on the order of at least ten or more staff, with funding of several hundred thousand dollars. California, is a much larger state than North Carolina, but with less

registered sources in DOE's 1605 (b) Registry. It has spent large sums of money developing their program but the program does not yet have all the required elements (e.g. mandatory for all with a reduction target) to insure its long term success in achieving reductions in GHG. Since this step does not seem likely in NC at the current time, this option is not fully detailed here. However, if the need arises, further analysis and related plans could be developed and provided.

A Sensible Skeleton for Building a NC Registry

If a registry were to be established in North Carolina, the discussions and options outlined below could provide a basic skeleton upon which to build positive steps toward a sensible GHG or Climate Change Registry in NC compatible with managing future mandatory reductions and targets:

Element 1: Encourage Interfaces with DOE, EPA and Other agencies

NC would continue a strong commitment to efforts to convince federal officials and offices of the need to provide positive and certain links between the DOE 1605 (b) Registry and the EPA Climate-Wise and Climate Leaders programs and that they should be cast in a background of an overall mandatory program with specific reduction targets. Through continued technical comment with DOE and EPA and by pursuing alternate options to have an enhanced registry to track companies in NC in a nationally and international recording system to record their emissions and reductions in an accredited manner, all related programs and offices in NC should continue to assert the need and help facilitate the changes needed. Political forces are likely important in the realization of the appropriate role, so education and provision of factual information to the officials throughout the State may be an important element to realize this aspect of the program.

NC would need to develop and expand programs to provide technical assistance to potential registrants and provide them with the information on how to report emissions into the existing and developing programs. A monitoring function is also proposed whereby activities in one program automatically trigger the request and assistance function to assure this cross-reporting among the existing programs is complete. Some enhanced electronic ties may even be possible as the reporting details unfold.

The efforts under this element would include continuing to try to get an independent verification process incorporated into the federal programs, if not incorporated into the pending 1605 (b) technical revisions. The reader is reminded that these important elements already exist for coal-fired utilities.

Element 2: Informal "Registration" of GHG via Existing Procedures

Each year, the Division of Air Quality inventories all (approximately 400) Title V facilities in the state for criteria and hazardous air pollutants (HAPs) as addressed by the Clean Air Act. The annual emissions reported for these point source facilities generally include all coal-fired utilities and other major burners of carbon fuels in the state. In addition, on a five year rolling cycle, the smaller facilities report their criteria and HAP emissions.

DAQ recommends that as quickly as the identified GHG's can be added to the pollutant table [presumably to begin with Calendar Year (CY) emissions for 2005 or 2006, reported in 2006 or 2007] and the inventory instructions (as a defined "air pollutant") so that the facilities begin "registering" their emissions annually. This level of effort does not envision a detailed and prescribed formal protocol, but reference to other available

calculation procedures, protocols and software available. It would not involve third party validation. There would be a preliminary and rather cursory review by DAQ engineers as part of the routine review of the annual inventory.

Amendments and revisions to the data system would result in the generation of annual reports and listings of emissions by facilities but would not be considered a formal and legally certified "register" for cap and trade or other refined monetary or legal purposes. It would be used as a resource for future prioritization and to assist buyers and sellers to independently find a potential counterpart. If a facility wished to purchase, sell or trade emissions with other facilities, this would be done as a private exchange not involving the State. This would also allow for further assessment of cut-off points to try to simplify and keep simple procedures involving the minimum of facilities with the maximum of pay-back in terms of future reductions.

In this context, the registration process would first be targeted at the Title V facilities as these are likely to cover the vast majority of the emissions (for most criteria pollutants, the Title V facilities account for 90% or more of the emissions from point sources within the state). Coal fired utilities would be required to continue to report to the Acid Rain Program, but also provide a copy of the reports to the DAQ within the existing data system, but also include any other fuel combustion sources not covered by the Acid Rain Program. The facilities would be encouraged to voluntarily report to other EPA, DOE and International programs as further identified below, following the rules and protocols that apply to those programs.

Even this level of support within DAQ will not be without resource impact. A minimum of one full time employee (by staff or contract) with identified continuing funding would be required to establish this effort and to keep it moving toward a reasonable target.

Element 3: A Program to Encourage and Facilitate Voluntary Reporting

It will be necessary for reporting to be required, eventually, before reliable targets and inventories can be established; and thus targets developed with plans for achieving the program envisioned in these recommendations. However, the first step relies on voluntary reporting to national databases, such as the 1605 (b), with the motivation that

- Company management is generally of good conscience as far as performing toward the public good.
- Future baselines cannot be established and maintained without participation in the initial registration process; therefore, it is in the economic interest of facilities to get their emission base established as quickly as possible.
- North Carolina government entities should be full participants and track emissions and make all efforts to reduce that other private sector participants undergo.

Thus, North Carolina DENR would initiate a strong effort to encourage both mandatory and voluntary efforts through all existing and new programs that are germane to the desired

results. An inter-departmental working group would be instrumental in planning and executing such efforts such that the results are productive.

Element 4: Harmony With State/Regional/Federal/International Aspects

It is obvious that NC is a small part of a global mechanism that must be considered as a whole; on the national and international scale. What is done in NC is important and will set a good direction and example. However, the part the state will play cannot accomplish significant gains on the global or total problem alone. It is not cost effective and does not guarantee future compatibility and ability to trade/sell emissions credits etc. without the registration being recorded in a national or international registry. Although the DOE 1605 (b) Registry is grossly deficient, it is a recognized national repository. With supplemental NC specifications and guidance from NC agencies, this mechanism has the capacity to serve the repository purposes of NC and its potential reporting entities. This may change as expected technical changes in procedures are issued (soon) by DOE which may require this to be reevaluated.

Environmental Stewardship Initiative

The DPPEA implements the Environmental Stewardship Initiative (ESI) already. This program provides a means for facilities to voluntarily apply for recognition at three levels of environmental stewardship within their activities in the state. There are a number of criteria that the candidates are judged against before being declared a Steward or other level. This plan/proposal includes using this ESI as a means for promotion, and education of facilities of the CA Registry efforts.

Continue Support and Participation for Existing State/Federal Programs

The several state and federal voluntary programs should continue to be supported in some fashion through encouragement and education. These include those mentioned below.

- **DOE's** (Past) climate change efforts carried out in NC in the past (previously **Climate-Wise**) should be continued in some fashion) Such efforts on the part of NC should result in facilities submitting their GWG data to the DOE Registry.

- **EPA's Climate Leaders** program should be acknowledged and supported, with emphasis on trying to convince the EPA and DOE to integrate their programs and meet additional requirements.

- **EPA's Environmental Performance Track** may provide a means for DENR to enrich contacts with this EPA Region 4 office and include green house gas reporting and reductions via EPA's Challenge Commitment initiative, adding to the ability to encourage reporting emissions to DOE's1605 (b).

- The President's Climate Vision program is somewhat redundant and focused on energy intensity as opposed to positive overall reductions, but is a means to encourage and demonstrate reductions that are possible.

Joint DAQ Efforts With DPPEA and other State Offices in NC

The above activities will require communication and coordination across multiple NC agencies. The DAQ, DPPEA and SEO appear to be the key actors in these efforts now,

but as the program and implementation are involved, many other (if not all) state programs may have some role. Even within DENR, additional discussions and developments are envisioned whereby the planting and tracking of forest and agriculture products would be done with new goals, a sensitivity and tracking of sequestration aspects of these areas could be managed within the framework of their overall program objectives. At some point in the (short term) future, it may be appropriate to develop an inter-agency task force or council to develop, review and coordinate state-wide activities for the common goals of this program within the State.

Coordination and Harmonization with State Energy Plan Objectives

The Energy Policy Council's far reaching State Energy Plan (SEP) shares focus with many of the goals and facilities encompassed by a North Carolina Climate Action (NCCA) Registry, as energy use is a common factor in most cases. This plan for NC's role in a NCCA Registry is supportive of, and endorses, the goals and conclusions of the SEP. It is important, however, to be able to define the goals relative to overall reductions in GWG and track progress. Therefore, the plan for this registry is to develop means and procedures whereby each element within the SEP has a defined baseline and a tracking function that follows it both in terms of absolute changes in emissions, but also in terms of reductions relative to what they "would have been" had there been no reductions attributable to the SEP. This documentation and tracking function would be an important part of the NCCA Registry's overall emphasis. It would likely also provide information needed for more effective management of emission reduction programs, priorities and resources in the future.

Promotion/Assistance & Education Efforts

DAQ and DPPEA already have an infrastructure of reporting entities or other facilities that would be candidates for participation in the NCCA Registry. This contact community is the target for additional information distribution and education activities on a periodic basis. Each facility would be informed and reminded of the opportunities available and updated on what assistance and advice are available to assist them to participate in the programs.

Element 5: Update the GHG emissions inventory for the State

It is difficult to keep a proper assessment of the effects of actions and growth without the existence of an inventory of current, past and continuing emission trends for the state and for various sectors within the State. An inventory of 1990 was developed in 1994 by an effort at Appalachian State University. This inventory needs to be reviewed and updated so that it becomes a better overall management tool and a means to track emission trends more authoritatively. This effort requires approximately $200,000 over a two-year period for the initial update and a periodic supplement to that for following years (3-5 year intervals are envisioned). This is an important part of this plan. Appropriations for this would be necessary before it can begin, but it may be possible to get some private support and participation in this effort from the NC utilities or others who may also have a need for the information/data. The results of this effort would be useful both to DAQ, other parts of DENR, and the State Energy Office, and would help track performance of programs and assess future priorities.

Element 6: NC DAQ Coordination with other (Outside NC) State Programs

North Carolina is certainly no "island" surrounded by other states that do not share the problem. Whatever is done in this State must be done in concert with (all) other states and within the same context as other nations in the world. This is critical if the aspirations of making a program for trading and selling credits is to work. Otherwise, the "currency" has a very questionable value and is subject to counterfeiting. Several efforts with others are planned or already underway, in parallel.

Southeastern States and Other Atlantic/Gulf Coast States

The coastal states from Virginia through Texas have a common tie to the same bodies of water, the Atlantic and Gulf of Mexico. Since these areas seem to be most at risk in terms of direct and obvious likelihood of potential impacts from climate change, there is a common tie. One of the objectives of this plan would be to initiate involvement and development of a Southeastern/Gulf States group that either works among themselves or as an adjunct to the NESCAUM efforts (below). Development of such ties takes staff time and resources and likely extensive input and discussions with other states and groups. Therefore, this will be developed over time on a schedule governed by staff time and resources and the willingness and reactions of other state offices.

NESCAUM

The Northeast States for Coordinated Air Use Management (NESCAUM) has undertaken the development of a Regional GHG Registry Collaborative effort among the eight Northeastern States. Over the last year, several Northeast states have taken firm actions toward registering and reducing GHG emissions, laying a foundation for possible GHG trading. In support of Northeast states looking to develop their own GHG action programs, their Demo Project has worked to support changes in the policy landscape that would encourage emissions reductions and lay the foundation for emissions trading at the state and regional level.

NC has been a constant observer and participant (listener) on calls and some aspects of this ongoing effort. NESCAUM invites representatives from other states to observe or participate at some level. There is the 'unofficial observer' level, the observer and the participant. NC by virtue of being on mail lists and invited to listen in to the calls, etc. is an unofficial observer and has been for several months, monitoring the discussion of founding decisions, various issues and problems, with their solutions; technical and administrative procedures, data system issues and decisions, etc. The major limitations to becoming recognized a full level observer is the matter of available personnel time and travel costs associated with attending various meetings in person. In spite of limitations, observers are provided opportunity to work on a more active level in sub-committees and work groups, which then involves more time and resources.

The effort also recognizes full partners which is much more significant. The full partners are included in final decision-making, as well as expected to provide more time and resources for meeting general obligations and responsibilities for the management and sponsorship of these activities. These states get to weigh in on ways that the process could better encourage all states to participate officially.

As this effort becomes more advanced, and as resources become available in NC, it may be productive for NC representatives to be elevated to an official observer level. At this level, one of the objectives would be to make North Carolina's program develop in a manner that it could provide outputs in harmony with those of NESCAUM. This could further its use this as a mechanism to organize Southeastern coastal states to unite both as a separate group, and also with the NESCAUM states in a more unified front of data harmony and usefulness for future trading programs.

California

California has one of the most extensive programs that has been developed, in terms of detail and sophistication. However, it is still voluntary and short of funding for future years. In some aspects, NC can make use of information and experiences from California, but in a direct interaction, little is expected to be directly transferable. However, the NESCAUM efforts are also extracting some of the usefulness from the California efforts and extending that to their work and NC can benefit from being a part of that group and its findings.

Other Legislative Interactions & Expectations Relative to This Proposal

The Legislature/General Assembly has raised the issue and need for a NC Registry in previous times. By default, the budget shortfall was partially responsible for the cut of funding for Climate Wise (the only NC Climate Action effort) from the budget. Interim bills and discussions have indicated that there should be a NC Climate Action Registry of some description. It is not clear how such efforts will be seen in the committees and on the floor of either body of the Legislature, but will likely be a subject of significant debate and compromises. Most recently, a Bill has been introduced that would provide funding for efforts similar to Climate Wise through support of Global Warming Initiatives, Inc., to the proposed sum of $400,000/year. This bill was not passed during the 2004 session of the Legislature.

Potential Comprehensive GHG Mitigation Plan for North Carolina

Several states who have been unable to advance the recognition and actions within their legislative bodies have take action through proposals, plans and actions within the executive branch to the level that can be accomplished without legislation. These efforts stand out as signs of movement in a positive direction. They also serve to bring public and legislative attention and needed debate to the topic. A "Comprehensive GHG Mitigation Plan for North Carolina" exists only in an initial concept stage, but may be further discussed and drafted over the next several months as feedback, interest and resources allow. Such a plan would likely encapsulate many of the ideas and concepts in this plan and further define a concrete set of steps for statewide actions that can, or should, be followed within North Carolina, and perhaps others, to accomplish the proper management and reductions in GHG.

Summary of Needs for a Practical Level of a Climate Action Registry in NC

This proposal contains several important and succinct points summarized below:

- Provide support for continued and expanded technical interfaces and political efforts with congress, DOE, EPA and other national and international agencies for a clear and strong national program.
- Implement an "informal" registration process with existing procedures for Title V permit holders in NC ($$-Continuing).
- Expand efforts to encourage voluntary reporting to federal and international registries.
    - Incorporate GWG "points" into Environmental Stewardship Program.
    - Encourage Continuation of Climate Wise Program and Reporting to DOE 1605 (b) Registry.
    - Encourage participation in EPA's Climate Leaders Program.
    - Incorporate GHG reduction principles into environmental education efforts.
    - Initiate/expand support of EPA's environmental Performance Track in NC with inclusion of Climate Change objectives.
- Joint DAQ Efforts With DPPEA, SEO and other State offices in North Carolina
    - Coordination and mutual assistance efforts with SEO and the SEP.
    - Mutual promotion and assistance efforts in conjunction with DPPEA, Small Business Office and Office of Environmental Education.
- Update the North Carolina GHG inventory, within resource constraints, and set an automatic update process into motion ($$-Continuing).
- Establish and maintain cooperative working relations with other states, regions and international bodies.
    - Work with others to establish a South Atlantic States GHG or Climate Change Group with mutual goals and expectations.
    - Observe and participate with NESCAUM on a continuing but informal basis, within resource limits.
    - Keep up to date on activities regarding the California Registry.
    - Stay attuned to changes and actions on the national (legislative) issues that might influence efforts in North Carolina.
    - Maintain cognizance of other state and national programs that would provide maintenance of a "State of the Art" knowledge within DENR.
    - Maintain efforts to keep informed on international developments, particularly as relate to international standardization of calculation and trading issues.
- Maintain an information base sufficient to keep the AQC, EMC, ERC, Legislature and Governor's Office well informed, and be responsive to questions and issues.
- Develop and coordinate a more "Comprehensive GHG Reduction Plan" for North Carolina that would encompass a broader focus on responding to national and international developments supporting a mandatory GHG reporting and reduction process.

APPENDIX D *EPC-RECOMMENDED ACTION ITEMS FROM THE NORTH CAROLINA STATE ENERGY PLAN (2003)*

The Energy Policy Council (EPC) reviewed the entire list of 93 policies and programs to determine which measures would require action by the Governor, North Carolina General Assembly, North Carolina Utilities Commission, or other regulating or administrative agency. From the entire list, the Energy Policy Council recommended the following 15 key legislative, regulatory, and administrative policies for action in 2003 and 2004:

Energy, Economic, and Environmental Issues

Exec-1 The North Carolina Department of Commerce and the State Energy Office should encourage and support economic development of energy-related enterprises whose products are intended to increase energy efficiency or use renewable resources, such as providers of specialized insulation and window products, heating and air conditioning equipment and controls, distributed generation equipment, solar and wind energy equipment, and fuel cells.

Exec-2 The State Energy Office should communicate the energy research being performed in the state to the North Carolina Department of Commerce for its recruiting and economic development strategy.

Exec-3 The North Carolina Department of Environment and Natural Resources should create a greenhouse gas registry to track emissions of carbon dioxide and other greenhouse gases, to establish baseline greenhouse gas emissions, and to demonstrate reductions in greenhouse gas emissions for potential greenhouse gas trading systems depending upon the availability of funding.

Alternative Fuels from Biomass

Exec-4 North Carolina should support the development of an alternative fuel industry through dedicated funding and grant matching of promising alternative fuel projects. These efforts should include agricultural waste processing facilities, biodiesel and ethanol refineries, fueling stations for alternative-fueled vehicles, production incentives for farmers and refiners, incentives for highly efficient or alternative-fueled vehicles, and education and awareness programs. Developmental efforts should focus on raising feedstock production levels and insuring all 100 counties in the state have alternative fueling infrastructure by 2007. In particular, the Energy Policy Council supports a state program to pay for alternative fuels development via a $1 to $2 fee applied to annual vehicle registration fees.

Exec-5 Based on the results of ongoing research and development studies, the North Carolina General Assembly should pursue strategies that convert animal waste into environmentally sound energy sources.

Alternative Energy Sources

Exec-6 The General Assembly should consider adopting net metering for application to all electric utilities in the state.

Exec-7 The General Assembly should evaluate a renewable portfolio standard (RPS) that complements the NC GreenPower program and fosters the development of a renewable electricity market. The RPS would require that all electric utilities increase the percentage of total distributed electricity that comes from renewable sources, such as hydroelectric, wind, solar, wastederived fuels, and agricultural fuels.

Exec-8 The General Assembly should reexamine the Mountain Ridge Protection Act as it pertains to wind energy while still protecting North Carolina's natural beauty.

Exec-9 The State Energy Office should assess and propose incentives and regulatory or administrative measures for development of renewable electricity generation facilities, solar water heating, passive and active solar space heating, and daylighting.

Exec-10 The General Assembly should require that all electric utilities in North Carolina provide generation disclosure of fuel mix percentages and emissions statistics on sulfur dioxide, nitrogen oxides, carbon dioxide, and mercury annually by bill insert and via website. The disclosure information should clarify to the consumer the environmental impact of residential electricity use.

Energy Use in the Public Sector

Exec-11 State agencies and universities, with coordination by the North Carolina Department of Administration, should reduce energy consumption in existing state buildings to save 20% by 2008, 4% per year or more for the next 5 years. The State Energy Office should submit an annual report to the Energy Policy Council, the Governor's Office, the State University System and other major energy users in North Carolina that provides data on energy saved in state buildings and universities by source and cost, energy efficiency activities undertaken in these buildings, the approximate investment in energy efficiency measures, and the overall economic costs and benefits of the program.

Exec-12 Working in conjunction with the State Construction Office, the State Energy Office should monitor, analyze, and report on the energy savings attributed to the new requirements on life-cycle cost analyses of the $3.1 billion higher education building program currently underway across the state, as well as future projects. The State Energy Office should be responsible for maintaining records that track the consequences of subjecting new public facilities to the newer life-cycle cost procedure.

Exec-13 North Carolina should facilitate efforts of local governments to finance energy efficiency and renewable energy projects; specifically, allow bundling of multi-jurisdictional energy efficiency projects to achieve economies of scale and improve opportunities for financing, restructure the underwriting provisions of the State Energy

Office's low-interest energy loan program, and provide training in energy efficiency measures to building managers in local government buildings.

Energy Use in the Residential Sector

Exec-14 North Carolina State Government should continue to support a strong low-income weatherization program. The state should review the effectiveness of energy conservation programs conducted through the weatherization program and analyze opportunities for improvements. The State Energy Office should develop programs, in addition to weatherization, to address energy-efficient housing in the low-income sector.
Funding for Energy Programs

Exec-15 The General Assembly should review options, such as a Public Benefits Fund or other means, to enable funding of the basic services provided by the State Energy Office and the recommendations in the State Energy Plan.

List of all 93 action items from the North Carolina State Energy Plan 2003

The measures above, with the prefix "Exec" are action items given high priority for 2003 to 2004.
The other actions are numbered by the chapter where they appear in the Energy Plan (e.g., 2-1 is in chapter 2).

Policies and Programs for Energy and the Environment

The Council also has a number of recommendations related to economic development, which are included in Chapter 10: Energy Use in the Industrial Sector.

Exec-3 The North Carolina Department of Environment and Natural
Resources should create a greenhouse gas registry to track emissions of carbon dioxide and other greenhouse gases, to establish baseline greenhouse gas emissions, and to demonstrate reductions in greenhouse gas emissions for potential greenhouse gas trading systems depending upon the availability of funding.

2-1 North Carolina should study opportunities for carbon sequestration in the agricultural, forestry, and other sectors. The immediate encouragement of these efforts will also insure these North Carolina industries will be ready to participate in national or international carbon trading programs as they are developed.

Energy Supply Policies and Programs

The following recommended policies and programs are related to the supply of conventional energy sources – primarily fossil fuels and nuclear energy. Many of the policies regarding energy supply are national in scope and thus beyond the purview of North Carolina. The Energy Policy Council has only included policies that the state could undertake.

3-1 The State Energy Office should work with propane dealers, the natural gas industry, electric utilities, key members of the agricultural sectors, and others concerned with alternative fuels to assess each fuel's role in the future of alternative-fueled vehicles in the state and consider how to improve the support structure via fuel supply stations.

3-2 The state should insure high priority for fuel supply by NC Department of Transportation emergency crews during weather and other emergencies – especially for strategic snow removal.

3-3 North Carolina should develop reciprocal agreements between state agencies in adjoining states (departments of motor vehicles, state energy offices, and state emergency response teams) on allowable hours of service for tanker and truck drivers during emergency situations (with clear definition of an emergency situation).

Electric Utility Policies and Programs

The following policies and programs are recommended by the Energy Policy Council regarding the electric utility industry. Several other chapters also contain policies relevant to the utility industry.

4-1 The North Carolina Utilities Commission is encouraged to promote policies that create diversity in energy supply such as natural gas, solar energy, wind energy, biomass, and hydrogen from renewable sources with particular emphasis on in-state energy development.

4-2 The North Carolina Utilities Commission is encouraged to consider increasing the availability of real-time pricing.

4-3 In determining the real costs of fuels, the North Carolina Utilities Commission is encouraged to consider the cost of externalities in economic analysis of supply resources.

4-4 The State Energy Office should explore the development of combined heat and power (CHP) technologies.

4-5 Because the December 2002, ice storm raised public interest in use of distributed generation (i.e., in facilities used as public shelters, residential housing, etc.), the State Energy Office should study distributed generation and appropriate applications.

Alternative Fuels Policies and Programs

The following policies and programs are recommended by the Energy Policy Council regarding alternative fuels for North Carolina.

Exec-4 North Carolina should support the development of an alternative fuel industry through dedicated funding and grant matching of promising alternative fuel projects. These efforts should include agricultural waste processing facilities, biodiesel and ethanol refineries, fueling stations for alternative-fueled vehicles, production incentives for

farmers and refiners, incentives for highly efficient or alternative-fueled vehicles, and education and awareness programs. Developmental efforts should focus on raising feedstock production levels and insuring all 100 counties in the state have alternative fueling infrastructure by 2007. In particular, the Energy Policy Council supports a state program to pay for alternative fuels development via a $1 to $2 fee applied to annual vehicle registration fees.

Exec-5 Based on the results of ongoing research and development studies, the North Carolina General Assembly should pursue strategies that convert animal waste into environmentally sound energy sources.

5-1 The State Energy Office should establish a panel to lead a detailed assessment of the potential for an alternative fuels industry in NC. The assessment should focus on the realistic potential for each type of alternative fuel, the economic and environmental costs and benefits, and recommendations for developing the industry.

5-2 The State Energy Office and other relevant state agencies should develop and implement a pilot project converting hog waste to methane or other fuels for the production of electricity.

5-3 The State Energy Office, Attorney General's Office, and Department of Environment and Natural Resources should assess and propose incentives for farmers to convert animal and crop wastes into energy.

5-4 The State Energy Office, Department of Agriculture, and Department of Environment and Natural Resources should support landfill methane gas projects through direct grants and loans based on need, as well as technical assistance.

Alternative and Renewable Energy Policies

Alternative and renewable electricity issues are complex because of the required linkage with the existing utility network. However, many states have adopted highly successful measures to foster development of in-state renewable electricity resources.

Exec-6 The General Assembly should consider adopting net metering for application to all electric utilities in the state.

Exec-7 The General Assembly should evaluate a renewable portfolio standard (RPS) that complements the NC GreenPower program and fosters the development of a renewable electricity market. The RPS would require that all electric utilities increase the percentage of total distributed electricity that comes from renewable sources, such as hydroelectric, wind, solar, wastederived fuels, and agricultural fuels.

Exec-8 The General Assembly should reexamine the Mountain Ridge Protection Act as it pertains to wind energy while still protecting North Carolina's natural beauty.

Exec-9 The State Energy Office should assess and propose incentives and regulatory or administrative measures for development of renewable electricity generation facilities, solar water heating, passive solar heating and cooling, active solar space heating and cooling, and daylighting.

Exec-10 The General Assembly should require that all electric utilities in North Carolina provide generation disclosure of fuel mix percentages and emissions statistics on sulfur dioxide, nitrogen oxides, carbon dioxide, and mercury annually by bill insert and via website. The disclosure information should clarify to the consumer the environmental impact of their electricity use.

6-1 A Solar Schools Program should be developed and incorporate renewable electricity generation, solar water heating, and daylighting to reduce fossil fuel use by schools, improve the quality of education, provide a real-world energy training lab, and make our citizens more aware of the potential for renewable resources.

6-2 The State Energy Office should work with the state's professional licensing boards to develop a certification program for renewable energy installers.

Public Sector Recommended Policies and Programs

The public sector is of key importance to the State Energy Plan for several reasons, including: (1) substantial potential exists for saving energy, (2) energy savings will help reduce the state budget shortfall and decrease the cost of government, (3) a firm commitment to improving the energy efficiency of state government will show that the state means to lead by example, and (4) reducing energy consumption will help improve the state's environmental quality. The Energy Policy Council recommends the following policies and programs for North Carolina's public sector.

Exec-11 State agencies and universities, with coordination by the North Carolina Department of Administration, should reduce energy use in existing state buildings to save 20% by 2008, a reduction of 4% per year or more for the next 5 years. The State Energy Office should submit an annual report to the Energy Policy Council that provides data on energy saved in state buildings and universities by source and cost, energy efficiency activities undertaken in these buildings, the approximate investment in energy efficiency measures, and the overall economic costs and benefits of the program.

Exec-12 Working in conjunction with the State Construction Office, the State Energy Office should monitor, analyze, and report on the energy savings attributed to the new requirements on life-cycle cost analyses of the $3.1 billion higher education building program currently underway across the state, as well as future projects. The State Energy Office should be responsible for maintaining records that track the consequences of subjecting new public facilities to the newer life-cycle cost procedure.

Exec-13 North Carolina should facilitate the efforts of local governments to finance energy efficiency and renewable energy projects; allow bundling of multi-jurisdictional energy efficiency projects to achieve economies of scale and improve opportunities for

financing, restructure the underwriting provisions of the State Energy Office's low-interest energy loan program, and provide training in energy efficiency measures to building managers in local government buildings.

7-1 North Carolina statutes should require that designers of all new public buildings provide estimates of projected energy consumption and energy costs for the building prior to construction.

7-2 The State Energy Office should work with the North Carolina Department of Public Instruction to review prototype school designs listed on the Department of Public Instruction's Web page and determine how best to integrate improved, more efficient designs.

7-3 The North Carolina Department of Administration should implement high performance building guidelines developed for North Carolina in all new public buildings and also develop and implement high performance guidelines for new public housing.

7-4 The North Carolina Department of Administration should develop performance contracting procedures and other ways to finance energy efficiency projects for state and local governments, university and public school systems, and public housing. The Department of Administration should provide technical support to implement performance contracting projects and provide quality assurance.

7-5 State agencies should lead by example by establishing a certain minimum level of electricity to be derived from renewable sources, such as the North Carolina GreenPower program, or via installation of state-owned renewable energy projects.

7-6 North Carolina Department of Administration should require that all state facilities with motors larger than 5 horsepower to develop a motor maintenance program.

7-7 Local governments should be encouraged to implement the above actions and other energy efficiency programs.

Residential Energy Policies and Programs

The following policies and programs for the residential sector are recommended by the Energy Policy Council for implementation in North Carolina. While these policies alone will not achieve the level of savings depicted in the high efficiency scenario shown above, they will provide a starting point for improving the efficiency of residences in the State.

- Low-Income *W*eatherization

Exec-14 North Carolina State Government should continue to support a strong low-income weatherization program. The state should review the effectiveness of energy conservation programs conducted through the weatherization program and analyze opportunities for improvements. The State Energy Office should develop programs in addition to weatherization to address energy efficient housing in the low income sector.

- *Energy Codes in New Construction*

8-1 The State Energy Office should conduct a study on current compliance levels of residential and commercial buildings with the North Carolina state energy code. The study should make recommendations for improvements in compliance procedures and for energy code changes that are in the best interests of the state.

8-2 The State Energy Office should create an Energy Code Enforcement Assistance Program to provide additional energy code enforcement and outreach officials to serve across the state. The state should consider whether adding a state surcharge on all local building permit fees to support the program is feasible.

- *Manufactured Homes*

8-3 The State Energy Office should investigate technologies, incentives, financing options, and regulatory issues regarding minimum efficiency requirements for manufactured housing. At a minimum, the State Energy Office should encourage new manufactured homes to comply with the critical components of the state energy code for site-built residential units and promote Energy Star manufactured homes. The program should include a comprehensive statewide training program on the benefits and details of higher efficiency units.

- *High Performance Homes*

8-4 The State Energy Office should organize a statewide effort to develop criteria for a high performance building program to reduce the life cycle cost of new and existing buildings. The criteria should utilize provisions from other successful high performance programs, including Energy Star, programs developed by Advanced Energy Corporation, Southface Energy Institute's Earthcraft Home Program, the U.S. Department of Energy's Building America program, and others.

8-5 The State Energy Office should develop a comprehensive, statewide promotional campaign for high performance buildings.

8-6 The State Energy Office should continue its work to formulate and advance mortgage-based incentives for high performance new homes.

♦ *Training*

8-7 The State Energy Office should provide training on high performance buildings to builders, subcontractors, architects and engineers, landscape architects, code enforcement officials, utility representatives, building investors, developers, financial institutions, real estate professionals, appraisers, home inspectors, renovation contractors, educators, and prospective homeowners.

8-8 The State Energy Office should provide training for building professionals on specific targeted technologies including residential daylighting, solar water heating, heat pump water heaters, new insulation products, and advanced HVAC systems and controls.

Commercial Energy Policies and Programs

The following policies and programs for the commercial sector are recommended by the Energy Policy Council for implementation in North Carolina.

9-1 The State Energy Office should work with appropriate state agencies to provide a design review service that focuses on energy-efficient components and holistic, high-performance, design strategies for new commercial buildings. The design review procedure should include a systematic life-cycle cost analysis of a variety of energy technologies and strategies for each project. The service should seek to upgrade new buildings to meet high performance building guidelines developed statewide.

9-2 The State Energy Office should promote and develop guidelines for performance contracts, conduct workshops, and provide technical assistance on developing performance contracting documents.

9-3 The State Energy Office should research current and proposed incentive programs in North Carolina and other states and develop a state commercial energy incentive program for consideration.

9-4 The State Energy Office should promote the use of and provide training for commercial building energy analysis software to assist building owners with evaluating the best energy efficiency measures to implement in existing state buildings and other commercial structures.

9-5 The State Energy Office should develop an energy audit program for existing commercial buildings to assist building managers with implementing the most energy efficient and cost effective improvements for commercial renovation projects.

Industrial Energy Policies and Programs

The following policies and programs are recommended by the Energy Policy Council for the industrial sector.

♦ *Industrial Energy Assessment and Efficiency Programs*

10-1 The State Energy Office should increase funding for industrial efficiency programs to enable the Industrial Extension Service, Industrial Assessment Service, Advanced Energy Corporation's industrial efficiency programs, and other similar programs in the state to expand technical assistance and analysis efforts to reduce energy use by the industrial sector in North Carolina. Funding should also be provided for follow-up efforts to facilitate implementation of cost effective technologies, including making contacts with vendors to procure bids, assisting with performance contractors, developing sample specifications, and providing other technical assistance. The State Energy Office should investigate and analyze alternative incentives to increase the implementation of industrial efficiency and renewable energy measures, including low interest loans, performance contracts, and incentive payments. The outreach and technical assistance program should support ongoing efforts to reduce water usage in industrial and municipal operations.

10-2 The State Energy Office should fund an Industrial Demonstration and Testing Program aimed at developing more efficient products and processes for North Carolina's industries. In addition, the Energy Office should convene industrial energy experts and industrial facility operators to create energy efficient solutions to targeted industrial processes that consume substantial energy in the state. Finally, the Energy Office should continue and expand its involvement in the federal Industries for the Future program.

10-3 North Carolina should evaluate whether facilities that repair or rewind motors should be certified or otherwise meet a state efficiency requirement.

- Incentives and Financing

10-4 The State Energy Office should develop rules for and conduct training programs on Performance Contracting for energy-related projects in industrial facilities.

10-5 North Carolina should create investment tax credits and other incentives for new and/or retrofitted manufacturing equipment to encourage modernization and efficiency improvements.

10-6 North Carolina should create tax credits for meeting high performance standards, including NEMA premium motors.

10-7 The State Energy Office should create a statewide voluntary challenge for industrial energy efficiency improvements.

10-8 North Carolina should create policies and regulations for distributed generation in the state, including incentives for deployment of "clean" distributed generation.

- Industrial Energy Technology Training

10-9 The State Energy Office should sponsor workshops on industrial energy efficiency around the state directed at industrial facility operators, design and process engineers, and owners. The workshops will describe the state-of-the-art in efficient technologies and describe the results of ongoing research efforts. The training effort should also address water-conserving practices around the state.

- Economic and Industrial Development Practices

Exec-1 The North Carolina Department of Commerce and the State Energy Office should encourage and support economic development of energy-related enterprises whose products are intended to increase energy efficiency or use renewable resources, such as providers of specialized insulation and window products, heating and air conditioning equipment and controls, distributed generation equipment, solar and wind energy equipment, and fuel cells.

Exec-2 The State Energy Office should communicate the energy research being performed in the state to the North Carolina Department of Commerce for its recruiting and economic development strategy.

10-10 The Department of Commerce should develop an industrial recruitment strategy to target appropriate industries to fit in resource efficient industrial developments (sometimes called industrial ecosystems).

10-11 In its recruitment efforts, the North Carolina Department of Commerce should give preference to industries that contribute to a more beneficial load curve and have minimal impact on the environment.

Transportation Energy Policies and Programs

The overall goals of the State Energy Plan's transportation policies are to increase the use of efficient vehicles and alternative fuels. The state's fleets can have higher efficiency and increased use of alternative fuels. Incentives may move employees and their employers to favor use of mass transit, as well as more efficient fleet vehicles. Incentives and publicity programs that are practical and affordable can encourage consumers to select vehicles that provide higher miles per gallon. It should be a priority of the State Energy Office to work in concert with North Carolina Department of Transportation to insure that policies and programs pertaining to alternate fuel use, mass transit, and transportation planning are implemented as soon as possible. Additionally, the State Energy Office should take the lead as a catalyst for bringing together the variety of plans and policies already drafted by numerous agencies and entities in the state of North Carolina.

11-1 The State Energy Office, Department of Revenue, and North Carolina Department of Transportation should assess and propose financial incentives for public and private employees who regularly ride mass transit systems and/or for their employers.

11-2 State agencies should convert at least 10% of their entire fleet to high efficiency (over 40 miles per gallon) or alternative-fueled vehicles by 2005 and 20% by 2010.

11-3 The North Carolina Department of Transportation should provide fueling capability for compressed natural gas, ethanol, biodiesel, and other alternative fuels at all state fueling stations by 2005.

11-4 North Carolina should implement light rail systems to serve transportation needs and direct development along higher population and employment corridors.

11-5 The State Energy Office should develop a statewide voluntary transportation efficiency program that rewards companies who qualify through a publicity and promotion program. The program would have the goals of increasing mass transit use and pedestrianism, increasing efficiency of commuter vehicles, increasing efficiency of company fleets, increasing use of alternative-fueled vehicles by company fleets, and allowing smaller parking facilities for those who demonstrate success.

11-6 The State Energy Office should provide technical assistance for local authorities to increase ridership on local transit systems.

11-7 The State Energy Office and the North Carolina Department of Transportation should become involved in ongoing statewide efforts to develop Smart Growth community design and redesign programs that increase pedestrianism, reduce personal vehicle miles traveled, and increase mass transit use. Smart Growth and Smart Roads programs also provide other benefits such as reduced urban and suburban congestion, lower commuting times, decreased air emissions, and increased productivity.

11-8 The State Energy Office should develop information resources on Smart Growth and energy efficiency that emphasizes the many advantages of the Smart Growth concept. The goal is to require developers, planners, and designers to consider energy use when evaluating future development projects. The information resources should also describe the concept of Smart Roads that seeks to relieve congestion by promoting the safe flow of traffic at increased average speeds.

11-9 The State Energy Office should conduct a statewide consumer campaign designed to encourage the purchase of more efficient vehicles or alternative-fueled vehicles, improve maintenance to increase vehicle efficiency, increase pedestrianism, and reduce vehicle miles traveled. The program should be coordinated with the state's automotive retailers' associations.

11-10 The North Carolina Department of Administration should work with the Department of Transportation to develop a coordinated set of strategies intended to reduce vehicle miles traveled (VMT) and increase the operating efficiency of vehicles within state government. The agencies should set specific target goals for VMT reductions.

Energy Education and Research Policies and Programs

The Energy Policy Council recommends the following programs and policies regarding energy education and research for implementation in North Carolina:

12-1 The State Energy Office should develop and sponsor training programs for community colleges and universities in fields related to energy efficiency and high performance buildings.

12-2 The State Energy Office should assist in the coordination of energy education programs with museums and help create an energy museum "on wheels" using existing resources, such as the Science House at NCSU or the Museum of Life Science, wherever possible.

12-3 The State Energy Office should sponsor regional "renewable demonstration centers" or, whenever possible, use existing ones (e.g. demonstration centers such as the North Carolina Solar House and the Energy Xchange, museums such as the Museum of Life and Science, and science centers such as Discovery Place).

12-4 The State Energy Office should create energy internships or apprenticeships for graduating college students and high school students to create the next generation of energy professionals.

12-5 The State Energy Office should provide a statewide award (e.g., a college scholarship) for the most outstanding energy-related science demonstration/experiment at the state science fair.

12-6 The State Energy Office and the UNC System should help the Education Departments of colleges and universities develop coursework for junior and senior undergraduates and graduate students in energy education.

12-7 The State Energy Office and the state's colleges and universities should help Community Colleges and other vocational schools develop coursework in energy efficiency and renewable energy to help spur the industry; such as training carpentry students in energy efficient, passive solar building design and construction. Include this training in voc-tech courses in high schools.

12-8 The State Energy Office should provide training to licensed professionals in the homebuilding industry focusing on energy efficiency and renewable energy sources to promote industry awareness and implementation of these technologies.

12-9 The State Energy Office should support development of a comprehensive information outreach program for consumer questions about saving energy and using renewables in their homes and businesses; information hotline via a toll-free telephone number; informative Web Page containing a wide array of publications available on-line; resources that include up-to-date information on renewables and energy efficient buildings, industrial facilities, and vehicles, as well as data on energy sources in the state; information on energy-producing facilities; environmental information related to energy consumption; and other energy-related information.

12-10 North Carolina should encourage schools to reduce school operating budgets by installing energy efficiency and renewable energy systems.

12-11 The State Department of Public Instruction should consider reinstituting its energy budget program, which provided guidelines for energy use per square foot by type of school.

12-12 The State Energy Office should work in partnership with the State Department of Public Instruction to plan school energy related initiatives and include a representative for energy-use in school facilities on the Energy Policy Council.

12-13 North Carolina should require that K-12 students learn about energy. Energy issues should be incorporated into the end-of grade tests.

12-14 The State Energy Office should sponsor a program to install solar equipment or other sustainable energy technologies on school buildings in every school district in the state.

12-15 The North Carolina Community College System should require that the community colleges' curricula provide a building science course, an energy design course for drafting programs, and a solar/renewable energy technology class.

12-16 The State Energy Office should establish a central repository for energy information. This energy data and policy analysis center should develop baseline information on energy consumption by state and local governmental entities. The center should also provide policy analysis for existing and proposed state energy policies.

12-17 The State Energy Office should conduct a comprehensive analysis of the existing Renewable Energy Tax Credits and determine if these credits should be expanded to include efficiency measures.

12-18 The North Carolina Energy Policy Council should update the State Energy Plan every five years and conduct a review of implementation of the plan on an annual basis.

12-19 State government departments and public universities should report their energy consumption and expenditures by fuel type on an annual basis to the State Energy Office.

12-20 Every two years, the State Energy Office should complete an assessment of energy use in public buildings to determine whether efficiency programs are having a significant impact on energy consumption.

12-21 Working in conjunction with the State Construction Office, the State Energy Office should monitor, analyze, and report on the energy savings attributed to the new requirements on life-cycle cost analyses of the $3.1 billion higher education building program currently underway across the state, as well as future projects. The State Energy Office should be responsible for maintaining records that track the consequences of subjecting new public facilities to the newer life-cycle cost procedure.

12-22 The State Energy Office should take the lead in conducting a statewide inventory of each public facility owned or leased by county and municipal government including K-12 schools and community colleges.

Funding Energy Policies and Programs

The Energy Policy Council recommends the following policy regarding funding of energy programs in North Carolina.

Exec-15 The General Assembly should review options, such as a Public Benefits Fund or other means, to enable funding of the basic services provided by the State Energy Office and the recommendations in the State Energy Plan.

North Carolina Department of Environment and Natural Resources

Michael F. Easley, Governor

William G. Ross, Jr., Secretary

November 19, 2004

TO: Environmental Review Commission Members

FROM: William G. Ross, Jr., Secretary

SUBJECT: Annual AFV Incentives Report

G.S. 143-215.107C(c) requires the Department of Environment and Natural Resources to report to the Environmental Review Commission each year on incentives to increase the use of alternative fuel vehicles. Attached is this year's report. If you have any questions, please contact Vicki Chandler at 919-715-0972.

One North Carolina Naturally

Incentives to Increase the Use of Alternative-Fueled Vehicles in Privately Owned Fleets in North Carolina

2004 Report to the Environmental Review Commission N.C. General Assembly

North Carolina Department of Environment and Natural Resources
Division of Air Quality

Legislative Background

Section 4.5 of Session Law 1999-328 (Senate Bill 953) states:

"The Department of Transportation, the Department of Commerce, and the Department of Environment and Natural Resources shall jointly develop recommendations for incentives to increase the use of alternative-fueled and low emission light duty cars and trucks in privately owned fleets. The Department of Environment and Natural Resources shall submit these recommendations to the Environmental Review Commission on or before 1 February 2000. The Department of Environment and Natural Resources shall report on progress in increasing the use of alternative-fueled and low emission light duty cars and trucks in privately owned fleets to the Environmental Review Commission on or before 1 October of each year beginning 1 October 2001."

A report jointly prepared by DOT, DOC, and DENR was presented to the ERC on March 16, 2000 which included a loan program to provide low-interest loans for construction of refueling stations; tax credits to allow private fleet operators to recoup the incremental costs incurred for changing fleets to alternative fuels; tax incentives for the public that provide additional incentives to purchase AFVs, and tax incentives to fuel providers to encourage investments in alternative fuel infrastructure. Representative Joe Tolson introduced House Bill 1213, "Alternative Fuel Vehicle Rebate and Infrastructure Grant Program", on April 12, 2001. Due to budget issues the bill was withdrawn. A similar bill was introduced in 2003 (H806), but had not passed when the General Assembly adjourned.

2004 Report

The following discussion highlights the Alternative Fueled Vehicle activities since the 2003 report.

2004 Legislation: House Bill 1636, Renewable Fuel Tax Credits

S.L. 2004-153 (HB 1636) provides two new income or franchise tax credits for construction of renewable fuel facilities effective beginning in 2005: 15% for a facility for dispensing renewable fuel and 25% for a facility to produce renewable fuel. Renewable fuel is defined as biodiesel or ethanol. Like the other credits in Article 3B, the new credits may be claimed against income tax or franchise tax. Each credit is limited to 50% of the amount of tax liability against which it is claimed. Any excess may be carried forward for up to five years. Although Article 3B is set to sunset January 1, 2006, the sunset for these two new credits would be 2008. This act became effective for taxable years beginning on or after January 1, 2005.

Triangle Clean Cities Coalition

In spring of 1999, the State Department of Commerce's Energy Division asked the Triangle J Council of Governments (TJCOG) to coordinate a Clean Cities program in the

Triangle. On March 19, 2001, the U.S. Department of Energy Clean Cities Program officially designated the Triangle Clean Cities Coalition (TCCC) as the 80th US Clean Cities Coalition.

At the 10th Annual National Clean Cities Conference in Ft. Lauderdale, Triangle Clean Cities (TCC) was recognized as one of the top ten Clean Cities coalitions in the country. The Triangle Coordinator, Anne Tazewell, received the 2004 Southeast Region Coalition Excellence Award on behalf of the coalition's legislative efforts and success in increasing the use of alternative fuels and AFVs by 121% in 2003. The City of Greensboro, a TCC member, also received an award for Excellence in Advancing Biodiesel. Greensboro had switched its entire fleet of over 750 diesel vehicles to biodiesel and used more than one million gallons of B20 (20% biodiesel 80% diesel) in 2003. Three other TCC stakeholders were acknowledged by the U.S. Department of Energy for their alternative fuel leadership – the NC Department of Administration for ethanol use, NC Department of Transportation for biodiesel use and Duke University for the use of compressed natural gas.

Centralina Clean Cities Program

The Centralina Clean Fuels Coalition (CCFC) program has been awarded the prestigious Clean City designation by the U.S. Department of Energy's National Clean Cities Program. Upcoming USDOE CC designation is planned for October 15, 2004 at the Adam's Mark in Downtown Charlotte. CCFC is sponsored by the North Carolina State Energy Office and has been supported by the Centralina Council of Governments (COG) for the past two years. Their new website is http://www.4cleanfuels.com.

The Clean Cities Program takes a unique, voluntary approach to AFV development, thriving on strong local initiatives and a flexible approach to building markets for domestically produced alternative fuels. CCFC stakeholders include local governments and State agencies as well as businesses such as major fuel providers and vehicle manufacturers. The following are just some of the current local initiatives underway:

- Bank of America, in conjunction with the Honda and Fuelmaker corporations, will sponsor a pilot program this fall to provide natural gas vehicles for bank associates to test drive.
- The City of Monroe expects to begin using biodiesel in over 70 of its fleet vehicles this year.
- The City of Charlotte and Mecklenburg County have committed to Clean Cities' program components including idle reduction strategies, hybrid gas/electric vehicle technology, and fuel economy initiatives.
- The first Biodiesel Refueling site is located at the BP station in Monroe (US 74/NC 200). The City of Monroe has switched to biodiesel for all of its on and offroad fleet operations.

Clean Cities designation means that CCFC stakeholders will be eligible for grants and federal funding to advance the usage of alternative fuels and vehicles. Nationwide, only

85 other local/regional groups have achieved this designation. CCFC in partnership with South Carolina's Palmetto State Clean Fuels Coalition and Sustainable Environment for Quality of Life (SEQL) will utilize an $18 k Fuel Economy grant to develop outreach and awareness activities and materials for their region.

2004 Biofuels Program

As part of the Triangle Clean Cities' biofuels program, nine grants were funded in the second round, including two ethanol projects (Durham and Wake Counties), two commercial B20 refueling stations (Durham and Cary), and one private fleet usage of B20 (Wolfline buses at NCSU). Additional funding was made possible for previous grantees including Duke University, the Town of Cary, Raleigh Durham Airport, Wake County, and the Garner BP station. The Biofuels Program has displaced almost 190,000 gallons of petroleum diesel with alternative fuels to the unregulated community. It is projected that this program will continue to displace about 63,000 more gallons, for a total of more than 6,000 barrels of oil.

Municipalities represent the biggest user of alternative fuels in the Triangle region although private fleets do sustain the necessary demand for B20 fuel at three commercial biodiesel stations. The following are a few of the private fleets utilizing B20: Shimar Recyling, Connex TCT, (NCSU Wolfline buses), and Duke University. Three alternative refueling stations have been added to the Triangle this year. Two commercial stations have biodiesel (B20), and the City of Raleigh has installed a compressed natural gas station (CNG) that is open to the public. There is also a B100 station open to Piedmont Biofuels Cooperative members in Pittsboro.

2004 Alternative Fueled Vehicle Incentive Grant

NC Department of Administration State Energy Office provided $100,000 to Triangle Clean Cities to fund the Alternative Fuel Vehicle (AFV) Incentive Project. Five projects received awards ranging from $8,550 to $25,000 to help buy down the incremental costs of the fuel, vehicle purchase, or to construct an alternative refueling site. The project goals are to displace petroleum use through the use of alternative fuels as well as to educate the public about the benefits of these fuels and technologies.

Project profiles:

- The City of Raleigh will purchase five dedicated CNG vehicles as well as E85 for their expanding fleet of E85 capable flex-fuel vehicles (FFVs). The City currently owns ten FFVs and is planning to purchase ten more in FY 04-05. The City has made arrangements with the State's Motor Fleet Management Division to purchase E85 at their downtown Peace and Person Street station and at their Blueridge Road site. Fuel keys will be issued to the City's FFV drivers that will only allow refueling with E85.
- Duke University Facilities Management Division (FMD) will purchase at least four GEM Neighborhood Electric Vehicles for use on campus. These zero emission vehicles will replace gasoline vehicles and are easily recharged using 110v outlets.

The university will be installing two new 110v outlets at its Facility Center and providing mechanic training for the new vehicles.

- Orange County is partnering with Orange County Schools to install a Fuel Maker CNG fast-fill fueling station at the Orange County School Maintenance Facility on Old 86 in Hillsborough. With a location between two major interstate corridors, I-40 and I-85, the intention of making this refueling site publicly available is very important. Orange County expressed intent to include B20 at the site, though no funds were requested for this purpose.
- The Department of Public Instruction will help offset a portion of the incremental cost of purchasing biodiesel for Chatham Public School's fleet of buses during the 2004-2005 school year. The fleet covers about 1.2 million miles each year and has already started testing a low blend of the fuel. During the 2003-2004 year DPI assisted the Durham Public Schools to begin using B20 in all 284 school buses and will continue with financial assistance for biodiesel use in 2004-2005 school year, as well.
- Piedmont Biofuels, Inc. is purchasing six 500-gallon tanks, pumps and fuel filters to be leased at no cost to various businesses and organizations in the region for on site biodiesel fueling. The tanks will be filled by Piedmont Biofuels, which recently purchased a 1,600-gallon tanker truck for biodiesel distribution. Piedmont Biofuels will also support the project by providing educational outreach and murals on the refueling tanks.

Sustainable Environment and Quality of Life (SEQL)

Centralina Council of Governments was awarded a $275,000 grant from the US Environmental Protection Agency to implement and expand regional efforts to protect the quality of life in the bi-state metro Charlotte region. This program brings together environmental, business and community stakeholders into a process of integrated planning and is administered by Centralina Council Governments in collaboration with Catawba Regional Council of Governments. SEQL is working to enhance local and regional decision-making through the development and implementation of Action Items relating to air quality, sustainable growth and water resources. Staff serves as a technical resource for communities and assists in seeking grants and developing educational resources.

The US DOE Clean Cities program recently expanded their program to have a more of a technology neutral focus on petroleum displacement which has opened the door to various fuel blends, hybrid vehicles, fuel economy measures and idle reduction strategies. NC Division of Air Quality (DAQ) along with partnering states of South Carolina and Georgia were awarded a $1.5 million dollar grant to deploy three Advanced Travel Center Truckstop Electrification (ATE) project along the Interstate 85 corridor. DAQ selected the Petro Stopping Center at Exit 157 on Interstate 85/40 near Mebane, which now offers 58 parking spaces where truckers can rest for the mandatory 11 hours without needing to idle their engines. SEQL has submitted a similar grant application under US EPA's "National Transportation Idle Free Corridors" solicitation and are hopeful that the Derrick Travel Plaza in Rowan County will become North Carolina's second ATE site.

Mobile Source Emissions Reduction Grant Program

The purpose of the Mobile Source Emissions Reduction Grants (MSERG) is to achieve actual reductions from mobile source related emissions in North Carolina to assist the State in maintaining the National Air Quality Standards for primarily ozone and carbon monoxide. In 1993, the North Carolina General Assembly passed Clean Air Legislation, which provided that beginning on January 1, 1995; certain portions of those taxes on the sale of gasoline in North Carolina would be used to fund portions of the State Air Quality Program. Funding for these grants is provided by a tax of 1/64 of a cent per gallon of gasoline sold, which currently generates about $800,000 annually.

Grants are awarded by DENR with the assistance of the Grant Review Committee. Each year the Grant Review Committee selects a focus for the upcoming grant year. Although other projects may be submitted and funded, priority is placed on projects addressing the goal for that particular year. The goal for the 2004 grants was to retrofit existing diesel school buses with diesel oxidative catalysts that will reduce the particulate emissions. The following applications were awarded funds in 2004 to purchase and install DOC technology on school buses:

Wake County Public School System - $100,000 for 100 buses
Guilford County Schools - $100,000 for 100 buses
Mecklenburg County Air Quality - $50,000 for 50 buses
Fayetteville MPO - $50,000 for 50 buses serving Ft. Bragg
Iredell-Statesville School District - $50,000 for 50 buses

In 2003 two MSERG grants were awarded for natural gas refueling stations in Asheville and Greenville. The City of Asheville received $400,000 for the construction of a publicly accessible compressed natural gas (CNG) fueling stations, training of mechanics on the new technology, and to purchase CNG vehicles. Partners in the grant include Mission St. Joseph Hospital and Buncombe County government. Asheville intends to install public access credit/debit card system for public use. Mission St. Joseph is investigating applicability related to local use of administrative vehicles including ambulances and courier services. Buncombe County is considering switching to CNG for their administrative vehicles and half and 3/4 ton pick-ups trucks. The City of Asheville is investigating applicability for administrative vehicles, half and 3/4 ton pick-ups as well as large vehicles if the technology is available.

Greenville Utilities was awarded $291,000 in 2003 to construct a fast-fill, publicly accessible CNG refueling station and to purchase CNG vehicles. Project completion was been delayed in 2004 but is expected to resume in 2005.

Southeast Alternative Fuels Task Force

In 2001, the Governors of Georgia, North Carolina, South Carolina and Tennessee entered into a Southern Air Principles agreement, which recognized that regional air quality problems must be addressed through regional approaches. Much work has been

accomplished including a final report in 2002 with recommendations for a joint multi-pollutant strategy to address ozone pollution, acid deposition to the problems with reduced visibility. Mobile strategies included innovative transportation options like alternative fuels and vehicle technologies. The Southeastern Alternative Fuels Task Force (SEAF task force) formed three work groups following a Forum held in Asheville, North Carolina. The subcommittees are: Infrastructure, Outreach, and Vehicles/Fleets with representatives from state agencies and the private sector.

The Outreach committee has plans to conduct a bi-annual workshop in each state to encourage broader use and availability of biofuels in the Southeast. The target audience includes fleet managers, fuel providers, and other interested stakeholders. Three regional workshops are planned for April 2005, 2007 and 2009. Another product this committee plans to create by April 2005 is a brochure that will encourage participation by public and private fleets, vehicle manufacturers, fuel producers and suppliers, retail marketers, and private individuals.

Important for the success of the SEAF is the need to compile state specific alternative fuel activity information and to serve as a clearinghouse and education center. The Infrastructure and Vehicle and Fleets committees are developing a comprehensive database and series of maps of alternative fuel stations. The 2010 plan will focus on biofuel refueling development along major highways in the four states. A list of AF fleets and potential fleets are being identified. SE state partners have a particular interest in finding suitable biodiesel additives that are designed to reduce NOx emissions.

North Carolina Solar Center Alternative Fuels Incentive Project

Every year the Department of Energy offers SEP grants for alternative fuel projects. Total funds of $98,000 were provided through the North Carolina Department of Administration State Energy Office. The North Carolina Solar Center (NCSC) received Statements of Interest in August 2004 with the purpose of increasing the use of alternative transportation fuels such as biodiesel (B20-B100), electricity, ethanol (E85), natural gas and propane. All vehicle and fleet operators and fuel providers in North Carolina, except those with project proposals in the Triangle region, are eligible to apply. Priority will be given to funding non-Energy Policy Act (EPAct) mandated fleets and can cover the incremental price of fuel, refueling related equipment and infrastructure, and/ or the incremental cost of purchasing an alternative fuel vehicle (AFVs). The maximum single award for any one project is $25,000.

2005 Model Year AFV/Advanced Technology Vehicles

Alternative fuel vehicles are widely available for public and fleet purchase. For more details on the availability as well as information related to these vehicles, go to the Alternative Fuel Data Center website:
http://www.eere.energy.gov/afdc/afv/afvehicles.html

The list of 2005 model year AFVs is available at
http://www.eere.energy.gov/afdc/pdfs/my2005afv_atv.pdf

A Review of Boundaries, Structure & Governance for the Metropolitan Planning Organizations in North Carolina

As Required by N.C.G.S. §136-200.2

October 2004

Prepared By:

North Carolina Department of Transportation

In Cooperation with the Metropolitan Planning Organizations

Definitions and Glossary of Terms

CRAFT: The Charlotte Regional Alliance for Transportation

FHWA: Federal Highway Administration

FTA: Federal Transit Administration

LRTP: Long Range Transportation Plan

MAB: Metropolitan Planning Area Boundary

MOA: Memorandum of Agreement

MOU: Memorandum of Understanding

MPO: Metropolitan Planning Organization

PART: The Piedmont Authority for Regional Transportation

TAC: Transportation Advisory Committee.
TAC is the governing policy board for the MPO. Membership includes: elected officials, members of local governments, N.C. Board of Transportation, an advisory non-voting member from FHWA, and other members as designated by the MOU

TCC: Technical Coordinating Committee.
It is comprised of staff representatives of various member governments, NCDOT, FHWA, transit providers, etc.

TIP: Transportation Improvement Program

3-C Planning Process: Cooperating, Coordinating, and Continuing planning process

UZA: Urbanized Area Boundary.
The Census designated boundary based on population of 50,000 or greater and population density of more than 1000 per square mile

MPO Evaluation Report

N.C.G.S. §136-200.2, Decennial review of the metropolitan planning organization boundaries, structure, and governance:

(a) Following each decennial census, and more frequently if requested by an individual metropolitan organization (MPO), the Governor and the Secretary of Transportation, in cooperation with the affected metropolitan planning organizations, shall initiate an evaluation of boundaries, structure and governance of each MPO in the State. The goal of the evaluation shall be to examine the need for and to make recommendations for adjustments to MPO boundaries, structure and governance in order to ensure compliance with the objectives of 23 U.S.C. 134. The Secretary of Transportation shall submit a report of the evaluation process to the Governor and to the Joint Legislative Transportation Oversight Committee.

Pursuant to the requirements of the G.S. 136-200.2, the North Carolina Department of Transportation (NCDOT) in cooperation with the Metropolitan Planning Organizations (MPOs) has conducted an evaluation of MPO boundaries, structure and governance. The Transportation Planning Branch of NCDOT has been coordinating the evaluation process and has on file the completed evaluation reports for all MPOs, which includes consideration of all factors prescribed by G.S. 136-200.2.

The following report is a summary of the review of and recommendations for each of North Carolina's seventeen MPOs. Based on this report, no special MPO funding and staff assistance is requested at this time as none of the contiguous MPOs are considering consolidation.

1--Capital Area (CAMPO):

Area: Wake County. Contiguous to the Durham-Chapel Hill-Carrboro (DCHC) MPO.

Evaluated: 2000 Census Urbanized Area (UZA) Boundary Map, Metropolitan Area Boundary (MAB) Map, Thoroughfare Plan, Long Range Transportation Plan (LRTP), and the MPO Memorandum of Understanding (MOU).

Recommended Changes or Modifications:
Boundaries: Yes, in progress
Structure: None
Governance: None

CAMPO, in cooperation with the DCHC MPO, completed an MPO Organization Study, in 2003. The Capital Area and DCHC MPO's are determining what changes to the MPO boundary, governance and structure, if any, are needed in order to adequately plan for the year 2025.

The DCHC MPO and CAMPO are actively discussing the formation of various joint committees and other regional structures with which to better plan for the year 2030.

2--Durham-Chapel Hill-Carrboro (DCHC):

Area: Durham County, portions of Orange and Chatham Counties and is contiguous to the Capital Area MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, DCHC MAB, Thoroughfare Plans, and the MPO Bylaws and Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes, in progress
Structure: None
Governance: None

The DCHC and CAMPO MPO's are actively discussing the formation of various joint committees and other regional structures with which to better plan for the year 2030.

3--High Point:

Area: Davidson, Forsyth, Guilford and Randolph Counties and is contiguous to the Greensboro and Winston-Salem MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, High Point MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: None
Governance: None
Based on the findings of this evaluation, there will be changes to the MPO boundary in order to adequately plan for the future year of 2030.

4--Winston-Salem:

Area: Davidson, Forsyth, Davie and Stokes Counties and is contiguous to the Greensboro and High Point MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes

Structure: None
Governance: None

The Winston-Salem Urban Area Transportation Advisory Committee (TAC) approved the expansion of the Metropolitan Area Boundary (MAB) map on November 21, 2002 to include portions of Davie, Davidson, and Stokes Counties, the City of King and the Town of Bermuda Run. The High Point MPO also expanded into the southeast corner of Forsyth County.

With the expansion of the Metropolitan Area Boundary, and the inclusion of new municipalities and counties within the expanded MAB, the Winston-Salem Urban Area TAC is studying several options for possible changes to the voting structure of the MPO.

5--Greensboro:

Area: Located in Guilford County and is contiguous to the High Point, Winston-Salem and Burlington-Graham MPOs.

Evaluated: The 2000 Census Urbanized Area Boundary Map, MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: None
Governance: None

The Greensboro Urban Area MPO is a member of the Piedmont Authority for Regional Transportation (PART). PART is a regional transportation authority among the four Triad MPOs (Greensboro, Winston-Salem, High Point, and Burlington –Graham) and numerous local governments within Alamance, Davidson, Forsyth, Guilford, Randolph, and Rockingham Counties. Presently, PART's role consists of the following emphasis areas: to plan for and operate a regional public transportation system, to operate a regional rideshare and vanpool program, to administer a regional out-of-county medical transportation program, coordinate the implementation of land use and transportation planning policies, and to serve as a forum for cooperative regional transportation planning. Through PART, the Greensboro MPO engages in an ongoing process of regional consultation and collaboration on issues regional significance. PART supports and coordinates these efforts as part of its mission to promote regional multi-modal transportation and land use planning.

The MPO's Metropolitan Area Boundary (MAB), where contiguous with the High Point Metropolitan Area boundary, has been amended to coincide with roadways, or in some instances, with the City of Greensboro corporate limits. Expansion of the MAB is not warranted at this time.

Institutionalization of existing cooperative regional planning structures and further development of certain regional planning functions are envisioned as enhancements in this area.

6--Burlington-Graham:

Area: Alamance and Guilford Counties. The Greensboro MPO is located to the west.

Evaluated: The 2000 Census Urbanized Area Boundary Map, Burlington-Graham MPO MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: None
Governance: None

7--Mecklenburg-Union:

Area: MUMPO (Mecklenburg-Union MPO) is located in Mecklenburg County and the western urbanized portion of Union County. Both the Gaston MPO and the Cabarrus-Rowan MPOs are contiguous to the Mecklenburg-Union MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, Mecklenburg-Union Metropolitan Area Boundary Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

The Charlotte Regional Alliance for Transportation (CRAFT) is an organization established to integrate the 3-C concept into the transportation planning process for those projects and programs of a regional scope. The ultimate goal is to ensure that regional transportation planning in the Charlotte metropolitan bi-state region is conducted in such a manner that is beneficial to the public good. CRAFT is currently comprised of members from the Mecklenburg-Union, Cabarrus-Rowan, and Gaston MPOs, Rock Hill-Fort Mill Area Transportation Study (RFATS), and the Lake Norman and Rocky River Rural Planning Organizations (RPOs).

The CRAFT structure will permit transportation planners in the region to work closely on matters of regional significance, while still being able to deal with those more localized issues that are vitally important to the community. CRAFT will also permit those making transportation planning decisions the opportunity to come together to discuss regional transportation issues. Those issues of regional significance include, but are not limited to

the following: air quality; regional travel demand modeling; regional transit issues; transportation improvement projects of regional significance, etc.

A memorandum of agreement (MOA) has been adopted that lays out the organizational structure of CRAFT. This structure is modeled after the basic MPO structure. CRAFT is governed by an Executive Committee made up of TAC chairs of the member organizations, the Metropolitan Transit Commission (MTC) chair and one representative each from the NC Board of Transportation and the SC Highway Commission. A Technical Committee of staff representatives from the urban areas guides the Executive Committee by providing technical support.

In addition to CRAFT, the Metrolina MPOs, RPOs and State Departments of Transportation have established a formal structure to guide the development of the regional travel demand model, long-range transportation plans and air quality conformity determination. This structure includes an oversight committee to guide the development of the regional model, long-range plan and conformity analysis and an executive committee to resolve issues that cannot be resolved by the oversight committee and to make the personnel and financial commitments required for the completion of these items.

Based on the findings of this evaluation there will be changes to the MPO Boundary in order to adequately plan for the 2030-planning horizon. The MPO Governance and Structure will be modified due to added jurisdictions.

8--Gaston:

Area: The Gaston MPO is located in Gaston County and is bounded by York County, South Carolina to the south, Cleveland County to the west, Lincoln County to the north, and Mecklenburg County to the east. The Mecklenburg-Union MPO (MUMPO) is contiguous to the Gaston MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, Gaston MAB Map, the 2025 Multi-Modal Long Range Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:

Boundaries: None
Structure: None
Governance: None

9--Cabarrus-Rowan:

Area: The Cabarrus-Rowan MPO is located in Cabarrus and Rowan Counties and contiguous to the Mecklenburg-Union MPO.

Evaluated: The 2000 Census Urbanized Area Boundary Map, Cabarrus-Rowan MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the 2030-planning horizon. The MPO Governance and Structure will also be modified due to the addition of new jurisdictions.

10--Fayetteville Area:

Area: The Fayetteville Area MPO is located in portions of Cumberland, Harnett, and Hoke Counties and there are no other MPO's contiguous to the Fayetteville Area MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Fayetteville Area MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the year 2030.

The MPO Governance and Structure has been expanded to include Hoke County. The MOU has been updated to include representatives from Hoke County on the TCC and TAC. Transportation planning data has been gathered for this new area.

11--Wilmington:

Area: The Wilmington MPO is located in New Hanover and Brunswick Counties. There are no other MPOs contiguous to the Wilmington MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Wilmington Metropolitan Area Boundary (MAB) Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes, the structure of the TCC and TAC changed and the MOU changed
Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for 2030.

12--Jacksonville:

Area: The Jacksonville MPO is located in Onslow County and there are no other MPO's contiguous to the Jacksonville MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Jacksonville Metropolitan Area Boundary (MAB) Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: None
Governance: None

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the year 2030.

13--Rocky Mount:

Area: The Rocky Mount Urban Area MPO is located in portions of Edgecombe and Nash Counties and there are no other MPO's contiguous to the Rocky Mount Urban Area MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Rocky Mount Urban Area MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the year 2030.

The Rocky Mount Urban Area MPO Governance and Structure has been expanded to include the Town of Nashville. The MOU has been updated to include a representative from the Town of Nashville on the TCC and TAC. Transportation planning data has been gathered for this new area.

14--Goldsboro:

Area: The Goldsboro MPO is located in Wayne County and there are no other MPO's contiguous to the Goldsboro MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Goldsboro MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: None
Governance: None

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the year 2030.

15--Greenville:

Area: The Greenville Urban Area MPO is located in Pitt County and there are no other MPO's contiguous to the Greenville Urban Area MPO.

Evaluated: The 2000 Census Urbanized Boundary Map, Greenville Urban Area MAB Map, Transportation Plan, and the MPO Memorandum of Understanding.
Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately pan for the year 2025.

The MPO Governance and Structure will be changed or modified to include the Town of Ayden and Village of Simpson.

16--French Broad River (Asheville):

Area: The French Broad River MPO, formerly known as the Asheville Area MPO, is located in parts of Buncombe, Haywood, and Henderson Counties.

Evaluated: The 2000 Census Urbanized Boundary Map, French Broad River Metropolitan Area Boundary (MAB) Map, the 2025 Asheville Area Long Rang Transportation Plan (LRTP), and the MPO Memorandum of Understanding (MOU).

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes

Governance: Yes

Based on the findings of this evaluation there will be changes to the MPO boundary in order to adequately plan for the 2030 horizon year. The 2000 Census expanded the MPO area to include eight new member governments: Henderson County, Haywood County, Hendersonville, Waynesville, Canton, Clyde, Flat Rock, and Laurel Park. Though not in the census, Maggie Valley and Mills River were invited to join the MPO area. Therefore, the MAB, as determined by the Asheville Area MPO Transportation Advisory Committee (TAC), included these two additional municipalities. For this reason, the MOU will be substantially altered.

17--The Greater Hickory MPO:

Area: The Greater Hickory MPO is located in the heart of the Hickory-Morganton-Lenoir Metropolitan Statistical Area, which is comprised of Catawba, Alexander, Burke and Caldwell Counties.

Evaluated: The 2000 Census Urbanized Boundary Map, Hickory-Newton-Conover MAB Map, the 2025 Multi-Modal Hickory-Newton-Conover Long-Range Transportation Plan, and the MPO Memorandum of Understanding.

Recommended Changes or Modifications:
Boundaries: Yes
Structure: Yes
Governance: Yes

Based on the findings of this evaluation, the MPO boundary and the MPO Governance and Structure will be changed and modified.

North Carolina
Department of Environment and Natural Resources

Michael F. Easley, Governor
William G. Ross, Jr., Secretary

October 15, 2004

MEMORANDUM

To: Environmental Review Commission Members

From: William G. Ross, Jr.

Subject: Status Report on Individually Permitted Discharging Systems
Beginning July 1, 2003 and Ending June 30, 2004
Fiscal Year 2003-2004

Pursuant to General Statutes 143-215.9A, the Department of Environment and Natural Resources submits the subject fiscal year report.

If any additional information or clarification is needed, please contact Vanessa Manuel at 919/733-5083, extension 532.

ATTACHMENTS

Cc: Alan W. Klimek, P.E.

Status Report on Individually Permitted Discharging Systems For the Period Beginning July 1, 2003 and Ending June 30, 2004.

Summary

North Carolina General Statute (N.C.G.S.) 143-215.9A requires the Department of Environment and Natural Resources to report to the Environmental Review Commission and the Fiscal Research Division on the status of facilities discharging into surface waters during the previous fiscal year. Facilities discharging into surface waters are required by N.C.G.S. 143-215.1 to first apply for and secure a permit from the Environmental Management Commission. As a result, the data provided within this fiscal report is captured for those facilities individually permitted with National Pollutant Discharge Elimination System (NPDES) permits.

The enclosed report details the inspections completed and the enforcement actions taken in North Carolina during fiscal year 2003-2004 by the Division of Water Quality. In addition, information on Special Orders by Consent is included. The report also includes a table showing the number of permits issued by region.

The enclosed tables list totals for each of the Department's regional offices as well as State totals. The regional offices are noted as follows:

- ARO – Asheville Regional Office
- FRO – Fayetteville Regional Office
- MRO – Mooresville Regional Office
- RRO – Raleigh Regional Office
- WARO – Washington Regional Office
- WIRO – Wilmington Regional Office
- WSRO – Winston-Salem Regional Office

If any additional information or clarification is needed, please contact Vanessa Manuel at 919/733-5083, extension 532.

ADDENDUM

The following is provided to support the information in the above status report.

- The Division of Water Quality does not have the data or management system in place to currently track information on the number of violations found during each inspection, the date of the violation, or the nature of the violation. A Basinwide Information Management System is, however, under development to address these needs. Funding has been allocated for the initial development phase. Completion of the system will require further funding. Therefore, at this time, the Division is unable to provide such information as requested in the amended G.S. 143-215.9A(a)(3).
- As found in Table 2, "Other Inspections" include:
  - **Audit Inspections**, a comprehensive review of all elements of a municipal's pretreatment program including a records review & an inspection of an industrial facility conducted once every 5 years;
  - **Bioassay Compliance Inspections**, evaluates the biological effect of a permittee's effluent discharge on test organisms using acute and chronic toxicity testing;
  - **Compliance Sampling Inspections**, a sampling inspection designed to verify the permittee's compliance with applicable permit self-monitoring requirements -- analytical results from representative samples collected during the inspection are used to evaluate the permittee's compliance;
  - **Diagnostic Inspections**, focuses on Publicly Owned Treatment Works that have not achieved permit compliance – the purpose is to identify the causes of noncompliance, suggest immediate remedies, and support current or future enforcement action;
  - **Operation & Maintenance Inspections**, focuses on the operation and maintenance aspect of a facility;
  - **Performance Audit Inspections**, inspections that include actual observation of the permittee performing the self-monitoring process from sample collection and flow measurements through laboratory analyses, data work-up and reporting;
  - **Pre-Treatment Inspections**, an annual inspection of a municipal's pretreatment program; and
  - **Toxicity Sampling Inspections**, same as CSI – however, increased emphasis is placed on toxic substances regulated by the NPDES Permit.
- Effective July 1, 1998, the Director of the Division of Water Quality delegated each Regional Water Quality Supervisor the authority to sign all Civil Penalty Assessments for fast-track enforcement actions for violations of NPDES Permit effluent limitations and/or monitoring frequencies in accordance with NCGS 143-215.6A.
- As found in Table 1, "Other Permit Condition Violations" may include
  - discharge violations (resulting from collection system overflows);
  - submitting late Discharge Monitoring Reports;
  - submitting late Toxicity Tests; and
  - permit condition violations (examples, violations of pre-treatment program, improper operation & maintenance of treatment works, or by-pass of treatment works)
- Due to the length of the post assessment process, total civil penalties assessed and total civil penalties collected will not coincide.

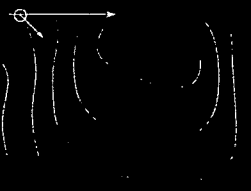
N.C. Division of Air Quality Issues Update

Environmental Review Commission Meeting



November 19, 2004

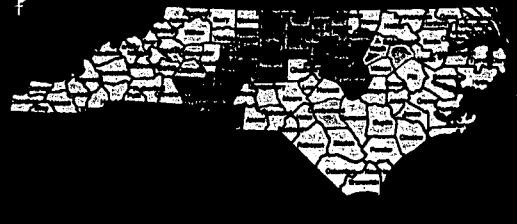
Keith Overcash, P.E.
Director,
Division of Air Quality

N.C. Status Relative to the Ozone Standard

Background

- New standard for ozone promulgated in 1997
- Standard challenged and litigated in the courts
- Upheld by the courts
- Standard is 0.08 ppm, maximum 8-hr. average
- Based upon the 4th highest reading at a monitor in each of 3 years Averaged over those 3 years
- EPA established three-year period for determination of attainment status to be 2001-2003

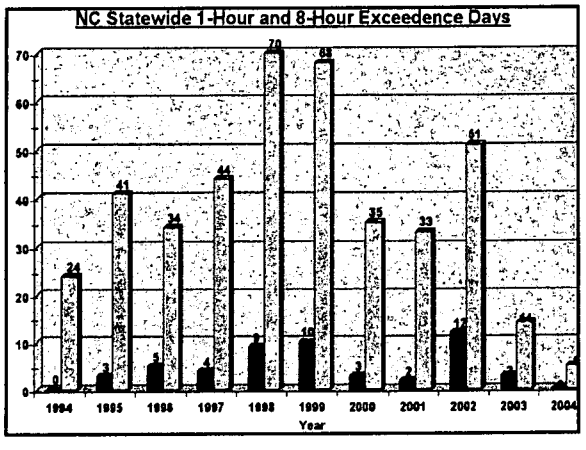
EPA's Boundary Designations for 8-Hour Ozone Standards for North Carolina



Not To Scale
November 19, 2004

"Nonattainment" Designation Timeline

- Immediate (June 15, 2004)
  - New source review for major emitters in the area
- One year
  - Transportation conformity
- Three years
  - State implementation plan (SIP)
- Five to six years
  - Attain standard



Ozone Monitoring Data Update

- Hickory/Unifour Area
- Fayetteville/Cumberland County
- Edgecombe/ Nash County
- Triad/Triangle/Charlotte-Mecklenburg Area

EAC Timeline *(cont.)*

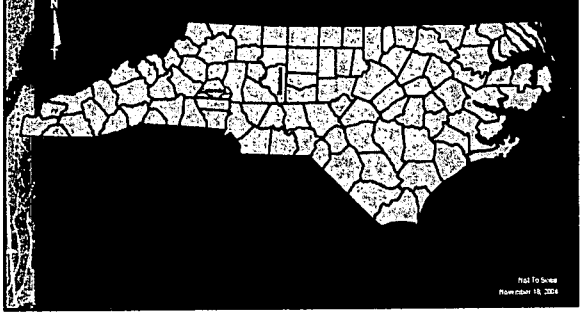
- December 31, 2004 – State adopts control measures into SIP & submits to EPA for approval
- 2005 – Areas implement local control measures
- June 30, 2006 – Progress assessment and report to EPA
- December 2007 – Areas must attain 8-hr ozone standard

N.C. Status Relative to the PM-Fine Standard

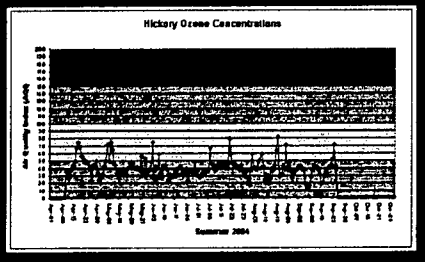
Background

- Similar history to ozone standard
- Standard is 15 micrograms per cubic meter (ug/M^3) annual arithmetic mean concentration over a 3-year period; 65 ug/M^3 24-hour concentration
- EPA established the 3-year period of 2001-2003 for determination of attainment status

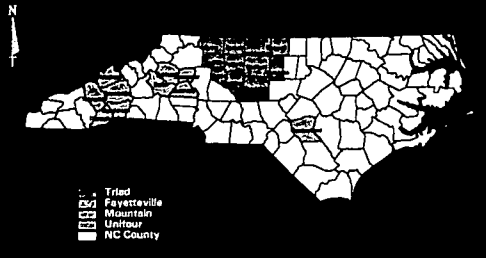
North Carolina's Recommendations on Boundaries for $PM_{2.5}$ Nonattainment Areas



Hickory Ozone Concentrations



State of North Carolina EAC* Areas

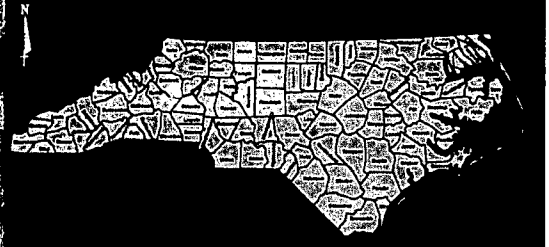


* Early Action Compacts

EAC Timeline

- December 31, 2002 - Compact signed by all parties in MSA (local officials, state air quality agency, and EPA Region)
- June 16, 2003 – Submit list of local control measures being considered
- March 31, 2004 - Local plan submitted to the State
- April 2004 - EPA designates "Compact Areas" as nonattainment, but defers effective date for these areas

EPA's Proposed Designation Areas for $PM_{2.5}$ Nonattainment Areas



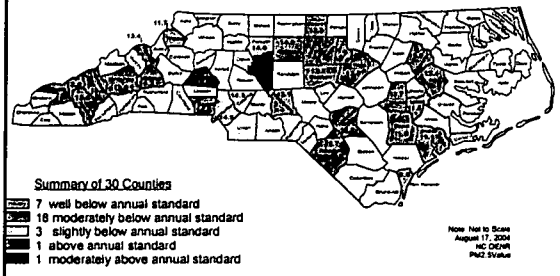
N.C. Comments to Support Recommendations (September 2004)

- Monitors in Guilford & Forsyth Counties are measuring attainment
- Emissions in Randolph County are primarily from Mobile Sources
- Emissions from power plant in Stokes County would not normally impact Davidson County monitor

Supporting Comments (*cont.*)

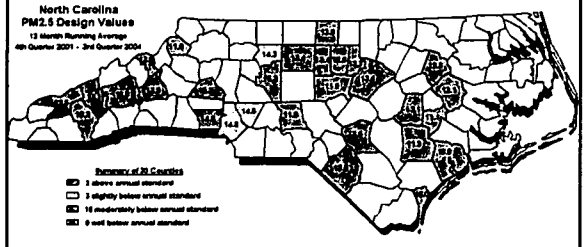
- Emissions in Caldwell/Burke Counties primarily mobile
- Catawba/Hickory monitor almost certain to be in attainment if 2004 data are included (Not likely now based upon latest data)
- Measures already taken by N.C. (CSA, I/M Program) and EPA (Mobile Source Initiatives)

North Carolina
PM2.5 Design Values, 2001-2003



Summary of 30 Counties
- 7 well below annual standard
- 18 moderately below annual standard
- 3 slightly below annual standard
- 1 above annual standard
- 1 moderately above annual standard

North Carolina PM2.5 Design Values
12 Month Running Average 4th Quarter 2001 – 3rd Quarter 2004



PM2.5 - *What Next?*

- EPA to make designations by the end of 2004
- Following a nonattainment designation, the PM2.5 SIP would be due 3 years later
- Attainment of the standard would be required 5 years later

New Source Review (NSR) Permit Rule Changes

- EPA has proposed two major changes to the rules
- December 31, 2002 - final rules made changes to applicability requirements
- August 2003 rule (equipment replacement provision or ERP) proposed a cost factor to determine whether modifications triggered review
- The ERP has been stayed by the Courts

December 31, 2002 NSR Final Rules

- Stakeholder process to develop State Rule
  - December 31, 2002 rule only
- 1st Meeting in Raleigh in September 2003
- 2nd Meeting in Hickory in October 2003
- Follow-up meeting with a Draft Rule on March 17, 2004
- Draft Rule to Air Quality Committee in April 2004

NSR Rule (*cont.*)

- EMC approval to go to Hearings at May meeting
- Hearings in August
- Results of Hearings – well attended, many comments
- Hearing Officer recommendations to EMC for approval of Final Rule in December

Construction Without on Air Permit

- New statute signed into law in 2003
- Allows existing permitted facilities to request construction of source before a permit is issued
- Requires Public Notice of Proposed Action in local newspaper

Construction Without Permit (*cont.*)

- Requires action by DAQ within 15 days of receipt
- 24 requests received to date
- Average turnaround time of 10 days

North Carolina Clean Smokestacks Act (CSA)

- NOx & SO_2 caps on emissions
  - -Tons/Year
  - -Caps per company – they decide on controls
- Phased compliance; 1 Jan. '07, '09, '13
- Actual reductions in N.C.
- Unique cost recovery feature
- Recommendations on Hg & CO_2; September '05
- Reduction credits held by the State

Utility Company Plans

- Compliance plans submitted
- 22 SO_2 scrubbers
- 36 SCR / SNCR units
- Most with combustion controls at least
- NOx controls in place starting in 2001
- SO_2 scrubbers scheduled to be in starting in 2005

2004 CSA (Second Interim) Reports

- Carbon Dioxide & Mercury
- Three-day conference to Solicit Information & Participation
- Stake-Holders encouraged to give Input
- Reports Provided to Environmental Review Commission (General Assembly) & the Environmental Management Commission on September 1

Mercury Report

- State of science updated
- Stated rule of leadership for N.C.
- Desire for N.C. Health Protection stated
- Range of options:
  - Continue study and defer rules
  - Follow lead of other states and require broad controls
  - Further study with specific targets for future rules

Mercury

- Important points pending:
  - EPA under order and has stated that revised standards (from existing – and other – multiple proposals – by March 15, 2005. THIS WILL BE PIVOTAL TO N.C. DAQ RECOMMENDATIONS)
  - No emission measurements have been made in N.C. Thus far (all estimated) nor are they currently required

Mercury – Other Points

- Existing CSA NOx Controls & SO_2 Scrubbers (Required) Result (Est.) in ~64% removal from base case coal fired power plants
- Removal at some scrubbed N.C. plants may range in the high 90%'s
- Some (Smaller/Older) plants will have no Hg removal
- Some concerns for local impact
- Some technologies may reduce Hg-only for relatively low cost – uncertainties exist
- Some testing of Hg removal technologies underway in N.C. and planned

CO_2 Report

- State of science updated
- Role for desired N.C. leadership stated
- Range of options:
  - Default to future Federal Actions
  - Study further then act
  - Mid-road voluntary and required actions
  - Aggressive plans with mandatory caps and tracking

CO_2 – Important Points

- CO_2/GHG are global
- N.C. is a relatively small emitter on global scale but a slice of the total
- US ~25% contribution of world's total
- Motor vehicles are on the same order as utility boilers for N.C.

Next Steps – Planned

- Continue to monitor national and global changes in information, requirements, and other actions
- DAQ prepare 2005 draft (this winter)
- Convene stakeholder meetings (2-3 each -Hg + CO_2) in spring of 2005
- Finalize in July/August and present to ERC & EMC by September 2005

The miracles of science

DuPont, Climate Change and Sustainable Growth

North Carolina Environmental Review Commission
November 19, 2004

William F. Bailey, Principal Consultant
E. I. DuPont de Nemours and Co., Inc.
Charlotte, NC

An Overview of DuPont Today

- A 202-year old global science company, solving problems in ways that makes people's lives better, safer and easier
- 135 manufacturing plants, 80 R&D facilities in 70 countries
- 60,000 employees
- Major business segments
  - Agriculture and Nutrition
  - Coatings and Color Technologies
  - Electronics and Communications
  - Performance Materials
  - Safety and Protection

DuPont Tyvek© Housewrap

DuPont is Transforming Itself

- Since ranking 15th in the Fortune 500 in 1997, DuPont has
  - Spun off its Conoco petroleum unit
  - Sold its pharmaceuticals and textile fibers businesses
  - Acquired two leading agriculture and biotechnology companies
- DuPont is recreating itself to achieve "sustainable growth"
  - Increasing shareholder and societal value...
  - While decreasing the environmental footprint of our operations...
  - Along the value chains in which we operate

Making "Sustainable Growth" Practical

- Our goal: grow profits while reducing our impact on society
- To do this, our manufacturing plants must
  - Reduce operating costs, energy use and emissions
- How will we reduce our costs and our emissions?
  - Use Six Sigma and other methodologies to improve productivity
- How do we know we're doing it?
  - Measure our progress versus an established baseline
- How do our shareholders and society know we're doing it?
  - Commit to meet a publicly-stated level of performance

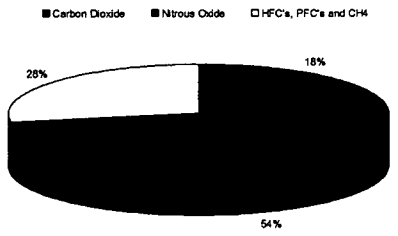
DuPont's Public Commitment on Energy

- We have committed to achieve the following by 2010
  - Reduce greenhouse gas emissions by 65% versus 1990
  - Hold total energy use flat versus a 1990 baseline
  - Supply 10% of total energy needs from renewable resources at a cost competitive with best available fossil derived alternatives

Greenhouse Gas Emissions in DuPont

- Most of our CO_2 emissions come from energy use
- But CO_2 is not our only Greenhouse Gas (GHG) emission
  - The manufacture of some refrigerants create HFC's
    - 1 pound of HFC-23 is equivalent to 11,700 pounds of CO_2
  - The manufacture of adipic acid creates N_2O
    - 1 pound of N_2O is equivalent to 310 pounds of CO_2
- These other GHG's dwarfed our CO_2 emissions

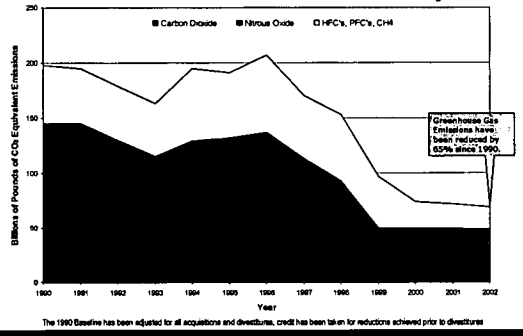
1990 GHG Emissions (CO_2 Equivalent)



Reducing Non-CO_2 GHG Emissions

- To reduce GHG emissions by 65%, we had to change the way we make two profitable products, nylon and HFC's
- We worked hard to develop innovative and cost-effective abatement methods for both HFC-23 and N_2O
- These changes cost over $50MM but they were worth it...

We Met Our GHG Goal 8 Years Early



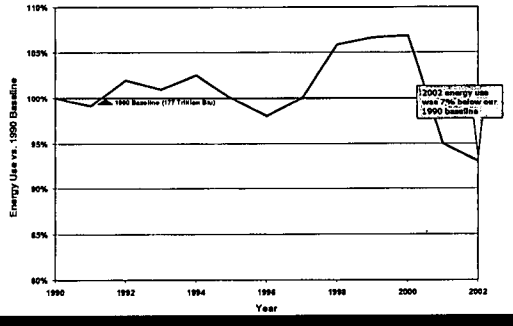
But What Are We Doing About CO_2?

- CO_2 emissions are driven primarily by energy use
- Energy use is largely a function of production
  - The more "stuff" you make, the more energy you use
- To grow earnings, you have to make more stuff, right?
- DuPont's approach to sustainable growth says "No"
  - We are striving to develop new, less energy-intensive products
  - We want to generate income from our knowledge + our products
  - We are using Six Sigma to improve yields and energy efficiency in our existing operations

Making the Case for Energy Efficiency

- Additional work is required to improve energy efficiency
- This work must represent an attractive value proposition
  - Potential benefits must outweigh cost of resources to work on it
- This is a complicated issue for most of our sites
  - Site may not have resources or knowledge to reduce energy use
- Our approach to improving energy efficiency
  - Uses Six Sigma to standardize improvement methodology
  - Leverages knowledge of the few to help the many
- We're making good progress here also...

DuPont Energy Use, 1990-2002



Key Elements of our Program

- Clear and measurable goals
  - Goals drive action and accountability
- Flexibility to find the lowest cost reductions
- Necessary measurement and tracking systems
- Public reporting of our progress
  - Corporate totals reported annually to the public via the DuPont Sustainable Growth Progress Report [1605(b) report to EPA]

NICHOLAS SCHOOL OF THE ENVIRONMENT AND EARTH SCIENCES
DUKE UNIVERSITY

Testimony before the
Environment and Resources Committee
North Carolina State Legislature
19 November 2004

William H. Schlesinger
Dean, Nicholas School of the Environment
and Earth Sciences
Duke University

Thank you for the opportunity to speak before you today. I am Dean of the Nicholas School of the Environment and Earth Sciences at Duke University—the nation's first school wholly focused on professional graduate education in environmental science and policy. We have 50 faculty and more than 400 students who, every day, study critical problems of the environment, including climate change.

It is, of course, the issue of climate change that brings me before you today. Despite a few nay-sayers, I have never before seen a scientific consensus that is stronger than that which accompanies predictions of future climate change. Earlier this year, the American Geophysical Union, the premier society of more than 10,000 earth scientists, issued a new statement on the climate change, which says, "Human activities are increasingly altering the Earth's climate. These effects add to natural influences that have been present over Earth's history. Scientific evidence strongly indicates that natural influences cannot explain the rapid increase in global near-surface temperatures observed during the second half of the 20th century."

Scientists from North Carolina are broadly in agreement with this statement, predicting a rise in the average annual temperature in this state between 4 and 10° F by the end of this century. The actual rise in temperature is not as alarming as its speed; we see little precedent for such a rapid change in temperature in any geologic record of the Earth's past. The most important cause of climate change is the emission of carbon dioxide during the burning of fossil fuels.

There is less consensus about predictions for changes in rainfall, but no doubt that a hotter North Carolina will be a drier North Carolina. Increased rates of evaporation will leave lower quantities of moisture in the soil, lower levels of groundwater, and less flow in surface streams and rivers.

What are the consequences and necessary responses of government and our citizens? Nearly every model of global climate change shows increased melting of the ice packs in Greenland and Antarctica and a rise in sea level. North Carolina will feel that impact. We can expect 18" of sea level rise this century, leading to the disappearance of the Outer Banks and inundation of much of our coastal areas. If not under water under calm conditions, these areas will be subject to catastrophic overwash during hurricanes, which themselves are predicted to be more frequent and severe with global warming.

We can expect large changes in what grows in North Carolina—the crops that feed us and the forests that form such an important part of our economy. More than one model shows increases in the productivity of hardwood forests, at the expense of conifers. North Carolina will not be treeless, but if I were a corporate executive in the forest products industry, I would seriously question whether I was planting the right trees today for harvest tomorrow. The rising levels of carbon dioxide in our atmosphere that cause global warming are known to increase the growth of trees, but also the growth of poison ivy and the production of pollen—a problem for all of you that may suffer from summertime respiratory problems.

We can expect other impacts on the health of North Carolina citizens. Looking globally, there is a strong correlation between climate and the occurrence of disease. A warmer North Carolina will certainly be more likely to harbor some diseases now confined to and associated with the tropics. The health community in this state can expect a greater epidemiology of diseases, such as dengue and malaria, along with a greater occurrence of direct heat-related deaths such as by stroke.

As I mentioned earlier, it is not so much the actual rise in temperature as the rate of rise that is of greatest concern. Humans live in hot places, and they can adjust their habitation to the realities of the coastline. People will live in North Carolina in the future, but it will be a very different North Carolina from today, and we are getting there very rapidly. An ounce of preparation and prevention would seem judicious. The potential disruption to our traditional society could be disastrous.

The citizens of North Carolina will not solve the global warming problem on their own. A molecule of carbon dioxide added to the atmosphere is the same whether it is from Raleigh or Rangoon. Conversely, the Earth will not avoid the problem of climate change unless all its citizens act together.

With its Clean Smokestacks legislation, North Carolina was a national leader in measures to clean up regional air pollution. We must do the same now with our response to climate change. Conservatives may believe that the evidence for global climate change is weak and the costs of action much too high, but to do nothing in the face of rapid change is not a conservative thing to do.

Thank you.

DENR Response to Western North Carolina Flooding
Environmental Review Commission – 544 LOB – Friday, November 19, 2004 9:30AM

- My name is Jimmy Carter. I work as Assistant Secretary for Operations and Development in the Department of Environment and Natural Resources.

- I am the first of a four-part presentation today on issues related to the storms that hit the western part of the state during September.

- Two storms had a major impact on the western part of the state – Frances came through on September 8 and Ivan followed on September 16, just 8 days later.

- It seems appropriate to treat the storms together as one big response, because our activity was nearly continuous from one storm to the next.

- Tropical Storm Frances released heavy rainfall and was quickly followed by Ivan – who came through causing more extensive wind damage, more widespread power outages and higher flooding levels.

- Our staffs in the affected region were on alert in advance of a disaster, and called to action during the disaster. Many of our programs have had a continuing role during the recovery period.

- DENR responded to the storm on several fronts. I'll give a brief rundown of activities from each program area:

Parks Department – Public Safety and our own park facilities

- Within 24 hours of the first impacts of Frances, 20 state park rangers were deployed as part of the State Emergency Response Team to assist the Asheville Police Department with patrols. Other rangers from all districts were placed on alert status, in case needed.
- In anticipation of Frances, thirteen parks were closed. In anticipation of Ivan, eleven parks were closed.
- The division's incident command team had already planned for the safe evacuation of the parks by ranger staff – and it paid off – so that no visitors or park staffs were injured and no visitor property was damaged through the evacuation and storm period.
- With Frances, we did have damage at South Mountains State Park [Burke Co.] – the entrance road and bridge approaches were eroded and a system of pedestrian bridges was destroyed.
- Park staff have been heavily involved in debris removal and aiding DOT in repair to bridge approaches. We've also developed a safe alternate route to the park's most visited feature – High Shoals Falls.
- South Mountains State Park is ready to reopen as soon as DOT replaces a guardrail.
- With Ivan, significant damage occurred at Mount Mitchell State Park [Yancey Co.] – The visitor center, the restaurant and a maintenance building suffered wind and water damage. Park staff along with workers from other parks in the West District performed emergency repairs to secure the buildings and reopen the park.

- Except for these two examples – South Mountains and Mt. Mitchell – where visitor safety was a concern – all state parks and recreation areas reopened within 24 – 48 hours after the storms.
- Parks staff also provided assistance to others in the area too. a five-man crew helped the National Park Service reopen a portion of the Blue Ridge Parkway between Asheville and the park. We contributed approximately 150 resource-hours and the use of division equipment.

Waste Management – Storm Debris Staging

- About 19 storm debris staging sites have been approved and activated by the Solid Waste Section. They all remain open and active at this time in various counties. [Avery (1), Cleveland (3), Henderson (2), Macon (3), Madison (1), McDowell (1), Mitchell (2)]
- The Solid Waste Field Staff in affected areas continue to provide technical assistance to local governments about removal, separation, staging and disposal of debris.
- They are also providing health and safety guidance for deconstruction operations associated with flooded mobile homes.
- This is an issue that has come up within the last week.
- There are aspects of dealing with these damaged homes such as separating household hazardous waste, white goods, asbestos and recyclable metals.

- During the storms, our Division of Forest Resources had an incident management team of about 40 people in Conover and a team of 25 in Butner to react quickly as needed.
- Forest Resources personnel assisted with emergency operations centers in each affected county.
- At one time, Forest Resources had six chainsaw crews assisting with road clearing and debris removal.
- We provided portable bridges (bridge mats) as temporary replacements for vehicle access at damaged stream crossings.
- Several crews from the BRIDGE program and teams of Forest Resources personnel constructed bridges for pedestrian access to stranded homeowners. [The name is a coincidence. BRIDGE program is our young offender rehabilitation program in Morganton and stands for Building, Rehabilitating, Instructing, Developing, Growing, Employing.]
- There was some damage to Forest Resources facilities – Two bridges that provide access to Gill State Forest (Marion, McDowell Co.) and the Mountain Training Facility at Crossnore (Avery Co.) were compromised by floodwaters of the Linville River.
- Heavy erosion at Linville River State Nursery in Crossnore damaged roads and seedling beds. Repair on those structures is almost complete. The Nursery is an integral part of the Western North Carolina Christmas tree industry. [a $125M industry]
- Numerous trails and roads at DuPont State Forest and some at Holmes Educational State Forest (Henderson Co.) were damaged and repair is ongoing with DFR personnel and equipment.

Dam Safety – Inspections of High Hazard Potential Dams

- The Dam Safety Program worked closely with the state Division of Emergency Management and local emergency managers before the hurricanes to identify known high hazard potential dams and after the storms to respond to emergency calls.
- High Hazard Dams are those that could threaten human life and cause greater than $200K in economic loss.
- Land Quality personnel from Swannanoa and Winston-Salem regional offices made over 150 emergency inspections within a short time period to determine if flood flows were endangering or had weakened dams.
- We know of seven dam failures, five of those were too small to fall under state jurisdiction. [Henderson Co.] One was a low hazard potential. [Transylvania Co.]
- The only high hazard potential dam that failed released water slowly enough that it did not do significant damage. [Avery Co.]
- Three other dams had the potential to fail, but Land Quality personnel provided onsite technical assistance for excavating emergency channels adjacent to two high hazard potential dams in Henderson County and one in McDowell County to relieve the overtopping spillways.
- Without intervention, these three dams would have likely failed, causing severe damage downstream.
- Our folks also monitored several other high hazard dams and advised if downstream evacuations were necessary.

- Evacuation was required for residents below Lake Susan in Buncombe Co. – They actually were evacuated twice – once during Frances and once during Ivan.
- Starnes Cove Lower in Buncombe Co. was evacuated.
- We had someone on site all night for both storm events to monitor these high-risk situations.
- We have a large number of dams in western North Carolina – many have been designed and constructed or repaired in recent years to current standards. They held up relatively well, even though the rainfall exceeded design standards in some cases. [762 dams in Asheville region – 294 are high hazard]

Water Quality – Tank releases and WWTP upsets

- Through the storm, several large petroleum tanks, over 100 home heating oil tanks and several hundred 55-gallon drums and propane tanks were recovered from local streams.
- The EPA came in to help us and set up an incident command post in our Swannanoa Regional Office. They took a lead role for the safe removal of containers. We also had a Coast Guard strike team in to assist in a coordinated fashion.
- During the height of the storm, staff estimate that as many as 100 of the wastewater treatment plants in the region were experiencing upsets.
- An upset is an incident beyond the reasonable control of the permittee causing temporary noncompliance.
- Situations causing upsets included operators unable to reach the facilities due to road closures, infiltration (from flooding) causing hydraulic overload, and there were power outages and equipment damage.

- There were problems with collection systems including: overflows, uncovered lines or lines washed away in some cases. Some lines were filled with debris, and equipment was destroyed.

Environmental Health – Drinking Water Systems

- Immediately after Ivan, 251 drinking water systems had service interruptions because of flooding or power outages.
- Each day, this number decreased as staff visited systems and took samples showing no contamination.
- We issued Boil Water Advisories and Use Restrictions in isolated areas of 10 counties [Buncombe, McDowell, Burke, Caldwell, Transylvania, Haywood, Avery, Mitchell, Yancey and Madison]. Most systems were returned to operational within 1 to 2 days.
- Our Division of Environmental Health issued temporary emergency authorization to county environmental health specialists in unaffected counties so they could provide assistance to flooded counties with reopening facilities such as restaurants and child care centers, and to inspect flooded septic systems.

North Carolina Department of Environment and Natural Resources

Michael F. Easley, Governor

William G. Ross Jr., Secretary

TO: Environmental Review Commission

FROM: Robin W. Smith, Assistant Secretary
Policy and Planning

RE: Stream Clearing Activities

DATE: November 19, 2004

Since Hurricanes Ivan and Jeanne, the Department has gotten a number of questions about removal of debris – including accumulated sediment – from mountain streams. Attached is some basic information about the environmental permits required for stream-clearing activities. In the western counties affected by the hurricanes, the United States Army Corps of Engineers is the primary permitting agency. The Division of Water Quality in DENR has a secondary role because a project requiring a federal permit must also get a certification from the Division of Water Quality that the project will not violate state water quality standards.

The attached information was developed specifically for counties outside the coastal area. In the coastal counties, the lead permitting agency is often DENR's Division of Coastal Management.

N.C. Dept. of Environment and Natural Resources
November 18, 2004

REMOVAL OF SEDIMENT AND DEBRIS FROM STREAMS

Summary: The U.S. Army Corps of Engineers should be contacted about the need for a federal permit if the activity involves: 1. Excavation of sediment or removal of rocks from a streambed; 2. Use of equipment that will be operated in the streambed; 3. Disturbance of the stream bank; or 4. Placement of sediment, rocks or other debris in or near surface waters or wetlands.

- Removing debris (such as tree limbs or objects washed into the water) from a stream does not require an environmental permit as long as there is no disturbance of the streambed or stream bank. Debris cannot be placed, either directly or indirectly, in waters or wetlands.

- Activities that result in debris, sediment or other material being placed in surface waters or wetlands will require a Clean Water Act (Section 404) permit from the Corps of Engineers.

- Activities that will disturb the stream bank or the stream bottom, such as excavation or removal of rocks in the streambed, may require a federal permit from the United States Army Corps of Engineer (COE).

- Activities that require a federal 404 permit (under the Clean Water Act) or a Section 10 permit under the Rivers and Harbors Act of 1899 also need a certification (called a Section 401 Certification) from the State of North Carolina that the activity will not result in a violation of any state water quality standard.

- Trout streams receive special protection under both federal and state environmental laws. To prevent high levels of suspended sediment in the water when trout are spawning, there is an October 15-April 15 moratorium on work in trout streams. The Corps of Engineers and the Division of Water Quality consult with the N.C. Wildlife Resources Commission on permits for projects affecting trout streams. If streambank erosion is already creating sediment problems in the stream and the proposed work would improve conditions, the agencies may waive the moratorium and allow a permit to be issued.

- The N.C. Sedimentation Pollution Control Act prohibits land-disturbing activity within a 25-foot buffer on either side of a trout stream, but allows for the issuance of waivers from the trout buffer if the impacts will be temporary and minimal. The Director of the Division of Land Resources in DENR has the authority to approve waivers from the trout buffer.

Permitting

The COE has a nationwide permit -- the Nationwide Permit for Maintenance (NWP 3) -- that covers some stream-clearing activities, including a limited amount of sediment removal. There is also a COE nationwide permit (NWP 13) that specifically covers stream restoration activities undertaken with federal funds from the Natural Resource Conservation Service (NRCS). Applications for coverage under a nationwide permit must be submitted to the COE. The Corps decides whether the activity qualifies for coverage under NWP 3, NWP 13 or another nationwide permit. Stream-clearing activities that go beyond the scope of any applicable nationwide permit require an individual permit from the COE and require a longer permit review.

DENR's Division of Water Quality has general Section 401 Water Quality Certifications for activities covered by NWP 3 and NWP 13; applicants should contact DWQ for information about coverage under a general 401 Certification.

N.C. Geological Survey - Hazards

Landslides from Hurricanes Frances & Ivan

November 19, 2004 ERC Meeting

EXHIBIT M

Geologic hazards — Landslides related to Hurricanes Frances and Ivan

The remnants of Hurricanes Frances and Ivan tracked across western North Carolina on September 8, and September 16-17, 2004. These storms resulted in loss of life. In addition to flooding, property damage and interruption of transportation corridors occurred from at least 75 landslides triggered by intense rainfall.

Other landslides have occurred in the past and will occur in the future in the North Carolina mountains. Hurricanes triggered widespread landslides in the North Carolina mountains in 1916 and again in 1940. A strong tropical depression in 1977 also triggered numerous landslides. Although many landslides occurred in remote areas, landslides caused fatalities in 1916, 1940 and 2003. Increased development in the mountains exposes more people to hazards from landslides.

Counties affected by landslides — Western North Carolina

The following western North Carolina counties were affected by landslides from hurricanes Frances and Ivan: Allegheny, Avery, Buncombe, Cherokee, Haywood, Henderson, Jackson, Macon, Madison, McDowell, Mitchell, Swain, Transylvania, Yancey and Watauga.

North Carolina Geological Survey Provides Assistance

Geologists in the Asheville Regional Office provided onsite technical assistance to state and local emergency managers, consultants and residents at the White Laurel community in Watauga County, Bear Rock Estates and Old CCC Road in Henderson County, and Peeks Creek in Macon County where landslides had destroyed houses, roads, caused fatalities. The geologists advised about the safety of the areas after the landslides for the rescue workers and what was generally needed to stabilize the areas. They have served on technical advisory committees to help determine the causes of the landslides and the potential for future landslides. The geologists also assisted the Blue Ridge Parkway in analyzing the landslides along the parkway. Post hurricane presentations have been made to local governments, the National Weather Service and interest groups.

Geologists in Raleigh also participated in the fieldwork and provided liaison with State Division of Emergency Management and the media. Additionally, helpful information was posted on the division's web page, which had over a thousand hits during this period. Geologists from both the Raleigh and Asheville offices helped to compile and update a GIS based landslide location database of the new landslides and post on the web page (http://www.geology.enr.state.nc.us/news.htm).

Peeks Creek Landslide — Heavy rains triggered the Peeks Creek landslide, sometime around 10:00 p.m. on Sept. 16, 2004. The path, or track, of the landslide on Peeks Creek on Fishhawk Mountain is about 2 miles long from near the confluence of Peeks Creek and the Cullasaja River.

Geologic hazards — Landslides related to Hurricanes Frances and Ivan

Examples of landslide damage from Hurricane Frances

The following shows selected examples of landslide damage from Hurricane Frances. Other examples of landslide damage are at http://www.geology.enr.state.nc.us/news.htm.

Watauga Co. — White Laurel subdivision — This image of a landslide was taken at the White Laurel subdivision located near Boone. This landslide appears to be related to an embankment failure. One home was destroyed, and eight condemned for occupancy. This image was taken September 9, 2004, by a North Carolina Geological Survey staff geologist.

Blue Ridge Parkway, NC — Sections are closed after rains from Hurricane Frances caused the roadway to give away in four places between Mount Mitchell and Linville Falls. The area in this image is near Milepost 348. Damage to the parkway is estimated to be $11 million. Some sections of the road could be closed for a year. This image is from the the National Park Service/Asheville Citizen Times.

Division of Land Resources, DENR
N.C. Division of Emergency Management
www.ncem.org (919)733-3867

I. Areas susceptible to landslides

- Natural or manmade steep slopes - usually greater than 30 degrees
- Areas below steep slopes, especially those near streams.
- Areas on hill or mountainsides where runoff accumulates.
- Disturbed or modified slopes on mountainsides.
- Where roads cross drainages or streams on mountainsides.

II. What to do if your house is threatened by a landslide

- Leave the house and evacuate the area immediately.
- Stay away from streams, creeks and drainages.
- If you cannot leave the house, move to an upper floor.
- Notify emergency response personnel or the fire department.

III. Indicators that more movement is likely following a landslide – especially following heavy rains

- Unstable material such as loose, wet soil remaining in the landslide scar area. Exposed, in-place bedrock in the scar and along the landslide path, however, may indicate most of the material may have already moved, and the scar area is more stable.
- Cracks in the ground allow water to infiltrate the soil and make the slope more unstable.
- Leaning or tilted trees or utility poles around the scar area.
- Water seeping or flowing from the landslide scar area.
- A terraced ("stair-stepped") ground surface around the scar area.
- Culverts, roads or blocked culverts directing runoff toward the unstable area.

IV. Different Types of Slope Movements/ Some Criteria for Recognizing Potential Slope Movements Landslides

Of utmost concern in the mountains of western North Carolina are landslides and rockfalls. Indicators for potentially unstable ground include the following:

- Open cracks in the surface above or on a slope.
- Cracking of the foundation of a building, retaining wall or other structure.
- Doors and windows out of plumb, or that stick or will not open and close properly.
- New cracks or bulges in pavement in roadways and sunken roadbeds.
- Soil moving away from foundations, decks or patios of a building.
- Broken or leaking water, gas or other utility lines.
- Leaning utility poles and street signs.
- Leaning, tilting or dying trees, tree roots stretched across cracks or areas of previous sliding.
- Springs, seeps or saturated ground in areas that have not typically been wet before.

Geohazards in North Carolina

N.C. Geological Survey – 2004
www.geology.enr.state.nc.us (919) 733-2423
Division of Land Resources, DENR
N.C. Division of Emergency Management
www.ncem.org (919)733-3867

Overview

North Carolina has significant geologic hazards that affect public safety and cause substantial economic loss. The primary geologic hazards facing North Carolina include:

1. Landslides occur primarily in the mountains, but also in the Piedmont and Coastal Plain along highway right-of-ways and river valleys. While it is difficult to predict when and where a landslide will occur and how big the event will be, field investigations and research can identify potential landslide areas and past landslide events. Landslides are likely to reoccur in the same places. Therefore it is important to know where previous landslides have occurred.

2. Coastal erosion and flooding from hurricanes, tropical storms, and nor'easters have tremendous impact along the 330-mile coastline of North Carolina. Current research suggests that ice-age buried river valleys, now under the ocean, may be a significant control on coastal erosion. Isabel Inlet, which cut through Hatteras Island in 2003, may have formed in such a geologic setting.

3. Ground collapse and subsidence above abandoned mines are a threat in the Piedmont and mountains. This type of hazard exists where development occurs over abandoned underground mine workings, the mine tunnels and shafts, which may extend for hundreds of feet underground. Although once relatively rare, the potential for damaging subsidence will increase as urban growth spreads into once sparsely populated areas where underground mining occurred.

4. Sinkholes mainly occur in the central to southeast Coastal Plain. Sinkholes result from dewatering of voids in the underlying limestone. Natural and human-induced changes in the surface and groundwater flow can lead to the formation of sinkholes.

5. Earthquake (seismic) risk within North Carolina is relatively low. However, three nearby seismically active areas that include the Charleston, S.C., the Eastern Tennessee, and the New Madrid seismic zones could pose an earthquake risk to North Carolina. A magnitude 5 or greater earthquake in these zones would not only cause structural damage in western North Carolina, but would likely generate landslides that would block major transportation routes.

6. Other hazards include:
    - acid-producing rock

- naturally occurring contaminants in groundwater, soil, and bedrock (e.g., arsenic, radon, uranium, and asbestos minerals)
- high shrink-swell soil.

North Carolina Geological Survey Work in Geohazards

- The State Geological Survey provides technical assistance in emergency situations when requested by emergency management agencies.
- The State Geological Survey is presently inventorying geohazards for a database of geohazards in North Carolina.
- This information on geohazards and critical infrastructure, once available in an integrated GIS format, can be used by state, local, and federal government agencies to prepare emergency response plans commensurate with the risks these hazards pose for their respective jurisdictions.
- In addition to emergency response planning, this geohazards inventory can be integral to zoning, construction permitting, and siting critical facilities in order to avoid potential problems and unnecessary risks.
- Funding for limited geohazards work in FY 04-05 is provided by a cost share grant from the Division of Emergency Management.
- Funding for future geohazards work is uncertain.

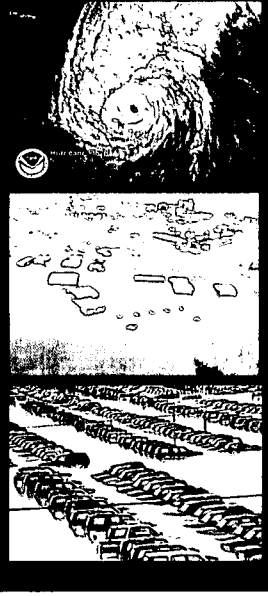
Floodplain Mapping in North Carolina

A New Generation of Maps

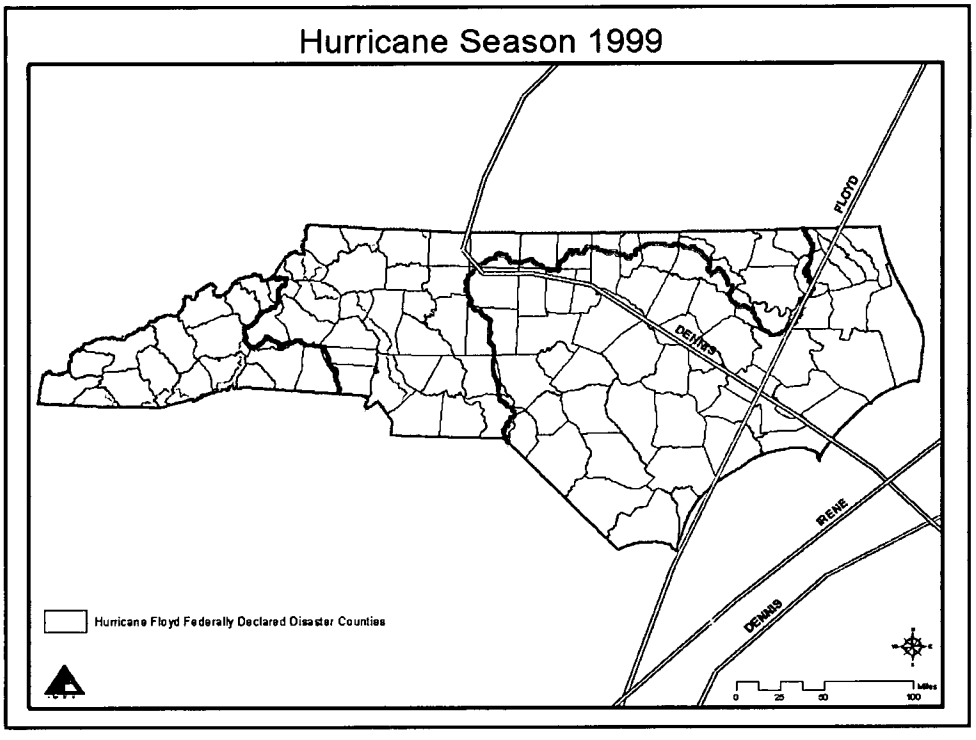
November 19, 2004 – Environmental Review Commission

Why is NC Undertaking the Project?

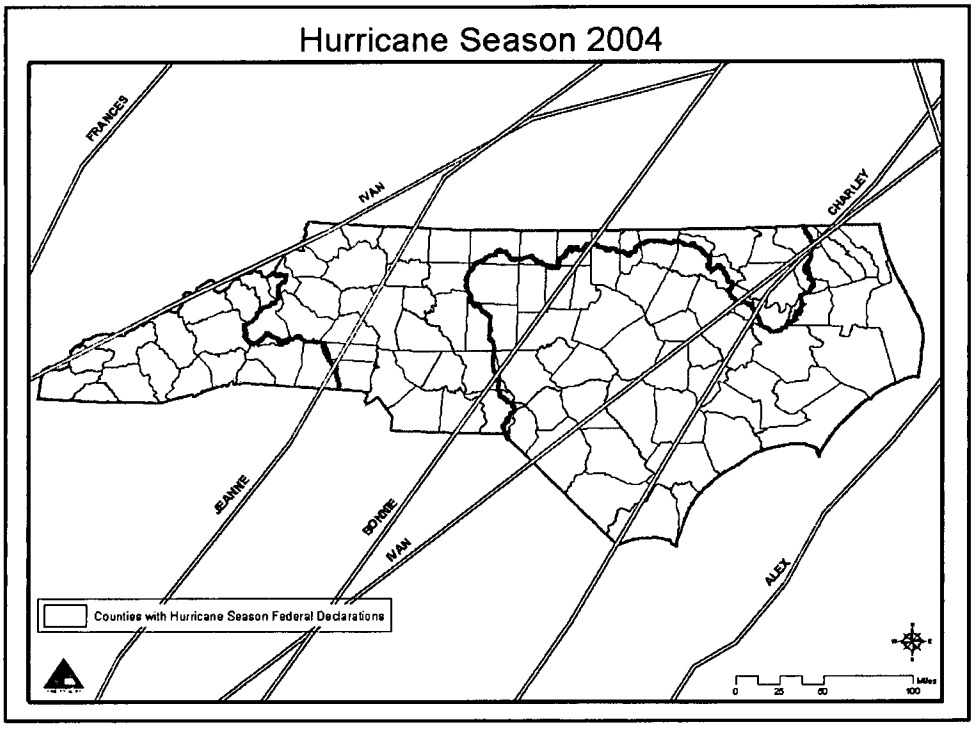
- 20+ Federally declared disasters in NC since 1989
- Majority of disasters have been due to flooding
- Hurricane Floyd revealed flood hazard data and map limitations
- 55% of NC FIRMs – at least 10 yrs old
- 75% of NC FIRMs – at least 5 yrs old
- 80% of properties damaged or destroyed during Floyd were not shown in SFHA
- $56M cost avoidance annually from flooding with new, accurate maps
- B:C Analysis of 7:1 - 3.5:1
- Many counties & communities have indicated a lack of resources to take on the responsibility



Hurricane Season 1999



Hurricane Season 2004



State Response / Strategies

- Strategy 1 - Establishment of a [illegible] to acquire, process and disseminate current, accurate, and detailed elevation data, flood hazard studies, reports, and maps (hard copy and digital).
- Strategy 2 - Establishment of North Carolina as a [illegible] through the FEMA Cooperating Technical Partners Program. This designation would establish North Carolina as the primary custodian for all Flood Insurance Rate Maps in NC.
- Flood Warning Strategy - Establish capability to determine and display what roads and bridges are currently inundated by flood waters and which ones will be in the near future (forecast).

- Engineering Studies / Mapping – ($9.8 million – FEMA funds)

New Generation of Maps – Phase III

- North Carolina is well under way with new statewide Flood Insurance Rate Maps
- The FIRMs are being generated digitally using state, county and municipal GIS layers (through partnering and leveraging of existing data)
- Hurricane Francis and Ivan demonstrated flooding hazards exist in Western part of North Carolina (Phase III)
- Existing FIRMs in Western North Carolina are outdated or inaccurate
- Phase III FIRM generation will require new elevation data ($5.2M) and new orthophotography for select counties ($236K)
- State funding will leverage FEMA funding for engineering and mapping - $9.8M

Thank You.

DRAFT

MINUTES
ENVIRONMENTAL REVIEW COMMISSION
December 7, 2004

The Environmental Review Commission (ERC) met on Tuesday 7 December 2004 at 9:30 a.m. in Room 544 of the Legislative Office Building.

Senator Daniel Clodfelter presided over the 7 December 2004 meeting. The following members were present: Senators Albertson, Clodfelter, Dorsett, Horton, Swindell and Weinstein, and Representatives Fox, Gibson, Hackney, LaRoque, Weiss and Williams. Mr. George Givens, Commission Counsel, Jeffrey Hudson, Assistant Commission Counsel, Susan Iddings, Assistant Commission Counsel, Jennifer McGinnis, Assistant Commission Counsel, Tim Dodge, Research Assistant, and Mary Watson, Commission Clerk were also present.

On 23 November 2004, notice was sent to members and interested parties via e-mail and regular mail. A copy of the notice is included in the attachments to these minutes as **Exhibit A**. A copy of the visitor registration and the agenda for the meeting are included in the attachments as **Exhibits B and C**.

Senator Clodfelter called the meeting to order and called on co-chairs for their remarks.

George Givens, Commission Counsel, was asked to explain the agenda.

Mr. Givens said the public staff planning meeting for this meeting was held on Wednesday 1 December 2004.

Mr. Givens said that staff is in the process of writing thank you letters to the faculty and staff of Duke University Marine Laboratory, the Institute of Marine Sciences at UNC, the Rachel Carson Estuarine Preserve, the Division of Marine Fisheries, the Division of Coastal Management in DENR, Dr. Michael Orbach and others who helped put together an excellent coastal site visit for the Environmental Review Commission.

Mr. Givens said that ERC may have longer meetings in January and is looking for feedback from members on whether a work through lunch meeting, with lunch being paid for by members, is feasible. He asked members to give their feedback to either him or one of the co-chairs.

Mr. Givens said that on 12 January 2005, ERC would meet jointly with the Joint Legislative Commission on Seafood and Aquaculture to discuss the saltwater fishing license. On 13 January 2005, the regular monthly business meeting will be held, and the Joint Meeting with Transportation oversight is scheduled for 20 January 2005.

Mr. Givens said that 25 January 2005 is being held for legislative proposals or wrap-up business with ERC.

Mr. Givens said that the staff planning meeting for the January 2005 meetings would be held on 5 January 2005 at 10:00 a.m. in Room 605.

Mr. Givens asked guests to sign the visitor registration forms and asked members to sign and send forward their reimbursement forms.

Mr. Terry L. Pierce, Director, Division of Environmental Health, DENR, gave a report on the resources needed to phase-in a statewide expansion of the Wastewater Discharge Elimination Program (WADE). A copy of Mr. Pierce's slides is listed as **Exhibit D**.

Mr. Pierce said that the WADE program is based out of Asheville and serves 26 western North Carolina counties. The program works with local health departments to identify straight piping and to keep discharges out of the streams, particularly those that serve water supplies.

Mr. Pierce said that when the WADE program began, it was assumed that straight piping was probably worse in the 22 western counties of North Carolina. The program has now expanded to 26 counties; however the impact of straight piping does not fall only on those 26 counties, it is a statewide problem.

Mr. Pierce said that straight piping presents a threat to public health and to the environmental quality of North Carolina waterways and communities across the state.

Mr. Pierce said that for the WADE program to expand to all 100 counties would take over $2 million. At present, there are no formal plans to expand statewide; however, there is a small amount of money that would be included in situations for low-income individuals to repair systems.

Senator Clodfelter asked Mr. Pierce if the EPA 319 Grants required a match from the State.

Mr. Pierce said that was correct.

Mr. Pierce next gave a report on the programs, activities, and priorities of the Division of Environmental Health. A copy of his slides is included in a handout listed as **Exhibit E**.

Mr. Pierce said that one of the areas that falls under the Environmental Health Section services is Methamphetamine Labs which are becoming an increasing problem in North Carolina.

Mr. Pierce said that new rules put into place for January 2005 to clean up meth labs. These new rules do not require that individuals be certified to do the cleanup and is left up to the property owner to do the assessment and cleanup.

Mr. Pierce said that Environmental Health Services would be working with other state agencies and personnel to help the state and local employees to be aware of potential hazards as they encounter meth labs.

Mr. Pierce said that cleanup and assessment would involve a lot of divisions within DENR and law enforcement in the cleanup of hazardous chemicals.

Mr. Pierce said that the Shellfish Sanitation and Recreational Water Quality Section is responsible for assuring water quality.

Mr. Pierce said that storm waters that settle into coastal waters carry sediment and pollutants, which can cause disease either through, skin contact or ingestion of water or consumption of raw shellfish.

Mr. Pierce said that coastal counties rely on revenue from tourists and also shellfish consumption. When shellfish harvesting areas are closed, harvesters and local economies face hundreds of thousands of dollars in losses.

Mr. Pierce said that an average of 18 percent of the 2.1 million acres of potential shell fishing waters are closed annually. The Shellfish Sanitation and Recreational Water Quality Section uses rainfall amounts to manage these additional closures. Some of these waters are high in bacteria with fecal contaminant after it rains and the waters remain closed until testing confirms satisfactory results.

Mr. Pierce said that most of the storm drains, which are major contributor to shellfish closures, have not been mapped.

Senator Clodfelter asked Mr. Pierce what percentage of the coastal and sound areas have been mapped.

Mr. Pierce called on Mr. Wayne Mobley, Section Chief for Shellfish and Recreational Waters, to answer Senator Clodfelter' question.

Mr. Mobley said that the GIS mapping has recently been started with most of the storms drains being mapped in relation to the recreational water quality program; however, for the shellfish areas, they are not very far along. Hopefully, this mapping will be completed in the near future.

Representative Gibson asked Mr. Pierce, that if there were no humans on the coast and the amount of suspended material, sedimentation and runoff were "x", when and how and where can we start evaluating what the storm systems being put into place would improve what is happening naturally.

Mr. Givens asked Mr. Pierce if the stormwater discharges were being mapped on the Oceanside as well as stormwater or is it just the Oceanside.

Mr. Pierce said they are trying to GIS a lot of the potential sources of pollution. He called on Mr. Mobley to answer Mr. Givens questions.

Mr. Mobley said that they are GISing the entire storm drains in the ocean. Some of the drains they do not have are some that discharge into the shellfish waters.

Mr. Givens asked if the efforts were on the Oceanside or just the estuarine side.

Mr. Mobley said that the effort has been with the recreational water quality program first because that is where the grant money was allocated. Most of those have been completed and the sound side drains are now being mapped.

Mr. Givens asked Mr. Mobley if their resources would be adequate to accomplish this.

Mr. Mobley said they would be.

Mr. Givens asked Mr. Mobley if they were responsible for monitoring water for swimming purposes.

Mr. Mobley said that was within his division.

Mr. Givens asked Mr. Mobley how well coordinated this monitoring is with the shellfish sanitation aspect.

Mr. Mobley said that it was very well coordinated. They use some of the same resources and equipment to sample both of these areas.

Senator Albertson asked Mr. Pierce where we are in the process of shellfish closures and would we see an additional increase in closures.

Mr. Mobley said that he did not have any graphs to show this information right now but they have seen a marked deterioration in water quality. One of the concerns is that the shellfish waters, which are managed by rainfall, are not reopened following a heavy rainfall as they were in the past.

Senator Horton asked Mr. Mobley if there were less harvestable shellfish waters in North Carolina than 10 years ago.

Mr. Pierce answered in the affirmative.

Senator Horton said that apparently our efforts to clean up the shellfish waters is not working and asked for an explanation of where we have failed and what we need to do to correct the problem.

Mr. Mobley said that one of the things that have taken place on the coast is a tremendous amount of development that creates freshwater runoff and larger impervious areas, which goes into our shellfish waters.

Mr. Mobley said that North Carolina produces very little shellfish for exporting. Most of the shellfish we eat in North Carolina is from Louisiana or the Gulf Coast.

Senator Horton asked how many acres of shellfish waters we have lost in the past ten years.

Senator Clodfelter said that this information was included in the Coastal Habitat Protection Plan.

Mr. Givens said that staff would be sure to get that information for Sen. Horton.

Senator Albertson asked Mr. Mobley if we have an adequate plan in place to protect this resource.

Mr. Mobley said that from the program standpoint, one of the most important things that are going to help protect the resource are the Phase II stormwater rules.

Senator Swindell added that when the shellfish season opened up, areas were closed to oystering at that time. The decision to close some of those areas was made just prior to the opening of the season and he was wondering was it was made without giving enough time to notify the fishermen.

Mr. Mobley said that they are required by FDA to do a triennial survey by collecting water samples over a three-year period. A permanent closure is not made until after all of the data is in. It is unfortunate that the data was released just prior to the opening of the shell fishing season and the area had to be closed.

Representative Weiss asked staff if legislation passed last year included language to strengthen coastal protections.

Mr. Givens said that the permanent Phase II stormwater rules, as adopted by the Environmental Management Commission and now in litigation, included a provision that limited impervious surface to 12 percent in areas that drain into Class SA waters. This provision is tied up in litigation over the permanent rules.

Mr. Givens added that when the legislature attempted to break the impasse through the ERC, it was decided to place into force the temporary rule adopted by the EMC. The temporary rule does not contain the 12 percent impervious limit.

Senator Clodfelter added that the legislation Representative Weiss referred to was stop-gapped to deal with the problems of 63 municipalities that were in non compliance. It did not, however, address the issues we are talking about today.

Mr. Givens said that he believed that the legislature would have to readdress that issue because the entire bill is scheduled to sunset in a ten-year timeframe.

Representative Weiss asked if this means we will wait 10 years before we address this issue or would some language be proposed to try to improve the quality of the water on the coast.

Mr. Givens said that this would be a relatively simple drafting exercise to amend last year's bill to include a provision.

Representative Williams asked what the current law is for impervious surfaces.

Ms. Robin Smith, Deputy Secretary, DENR, said that the current law for impervious surface threshold is 24 percent. What was purposed in the EMC's permanent rules was that the threshold for requiring engineered stormwater would be 12 percent. Again, this is not a limit; it is the threshold at which stormwater controls need to be used.

Representative Williams asked what the threshold is for the Triangle area.

Ms. Smith said that in the stormwater legislation that was adopted for those communities subject to Phase II stormwater, the threshold is 25 percent. There is now virtually the same threshold in the coastal area on essay waters as in any of the inland communities that are subject to Phase II stormwater controls.

Representative Williams said that we not only have a problem on the coast with stormwater runoff but we have a problem throughout the State. This problem needs to be addressed statewide.

Senator Albertson said that we have not been responsible with protecting water quality. If we are going to be responsible, we have to be about the business of fixing this situation.

Representative Fox asked why the shellfish situation in Louisiana is so much better than in North Carolina.

Mr. Mobley said that said that North Carolina has had oyster diseases in the last several years that wiped out our oyster crop. In Louisiana, they have tremendous acreage where the folks work together with the state, which allows them to lease large bodies of water to grow their own shellfish. Also, Louisiana's oysters grow year round where North Carolina's grows only a few months of the year.

Senator Clodfelter added that he thought this was a worthwhile format to remind us that we have a lot of work to be done on this issue throughout the state, not just on the coast. He suggested that co-chairs take this discussion under advisement and see what suggestions they may want to make to the ERC for further action.

Mr. Pierce continued with a report on the Public Water Supply in North Carolina.

Mr. Pierce said that there are over 7,000 regulated water systems in the state and 89 percent of them serve fewer than 500 people.

Mr. Pierce said that the Source Water Assessment Program, also known as SWAP, provides information on the condition of all drinking water sources in the state. The major highlight of this is a new online tool called SWAP info.

Mr. Pierce said that treatment of public water supply facilities is tightening federal standards ratcheting down puts compliant systems out of compliance.

Mr. Pierce that 44 percent had a monitoring and reporting violation and six percent violated contaminant standards in FY 2004.

Mr. Pierce said that as the monitoring compliance improves, it is expected that the detection of contaminants will increase as well. According to EPA, public water supply is doing a good job in tracking and issuing violation notices.

Mr. Pierce said that enforcement has not proven to be an effective means of bringing systems into compliance.

Mr. Pierce said that over $260,000 in federal monies has been passed along to water systems for risk management.

Senator Clodfelter asked Mr. Pierce is bottled water had to meet the same standards as public drinking water.

Jessica Miles, Section Chief, Public Water Supply Section, answered Senator Clodfelter's question by saying that bottled water is regulated through the Food and Drug Administration (FDA). The standards for contaminants they have to meet are pretty much the same as the drinking water standards; however the frequency of monitoring is a little different.

Senator Clodfelter said that bottled water may or may not be inspected; just as meat packing plants may or may not be inspected.

Ms. Miles said this was correct.

Senator Dorsett asked Mr. Pierce what the penalty is for violations and is follow-up done to make sure corrections have been made.

Ms. Miles said there is no set penalty for noncompliance. When a water system is in violation, a notice of violation (NOV) is issued. If they continue noncompliance and become a significant non-complier, they are put on a list and enforcement action is taken. The amount of the penalty for a violation of monitoring is based on the type of violation they have.

Senator Dorsett asked if anything more is done based on the seriousness of the violation.

Ms. Miles said that there is a public notice component of the drinking water standards and that is an enforceable item if systems do not provide the public notice as prescribed by law.

Senator Clodfelter asked Ms. Miles to name the most common violation for which an NOV is given.

Ms. Miles said that the most common violation is for failure to monitor.

Senator Clodfelter asked Ms. Miles what the most common cause of bad water is.

Ms. Miles said that the most common contaminant in water is fecal coloform or bacterial contamination.

Senator Horton asked how does the public know when the drinking water is bad and what are some types of fines that are issued.

Ms. Miles said that the public notice is different for different types of contaminants. For an acute contaminant, such as bacterial contamination, the public water system would need to notify the public within 24 hours.

Ms. Miles said that for failure to monitor, a penalty would more likely be issued than for a contaminant violation. Penalties can range up to $25,000 per day.

Senator Horton asked Ms. Miles that monitoring violations were more likely to be issued a fine than water that is contaminated.

Ms. Miles said that if a system fails to do monitoring sufficient to get on the chronic non-compliance list, a monetary fine would be issued designed to make noncompliance more expensive.

Senator Clodfelter asked Ms. Miles is a stop-service is ever issued because of contamination.

Ms. Miles said that they have the authority to revoke their operating permit, but when you have people without water, it poses a greater health risk for people not to have water at all.

Senator Horton asked if an issues problem is when there is water that is not fit to drink.

Ms. Miles said that the ability for people to drink the water is based on the type of contaminant that might be present in the water.

Senator Horton asked if fines are issued in these cases or just expect the problem to be fixed.

Ms. Miles said this was correct. If they do not take action to fix the problem, penalties are issued.

Mr. Givens asked Ms. Miles what she meant by problematic. He also added that his impression was that this particular program was one that EPA exercises a great deal of oversight and gives some type of evaluation of the state implementation.

Mr. Givens asked Ms. Miles what EPA says about our program.

Ms. Miles said that EPA has had good things to say about the program. They are focused more on the administrative details of administering the program. Do we properly track compliance, do we properly account for violations and do we promptly send the proper paperwork as a response.

Ms. Miles added that EPA is also interested in the overall quality of the water that is being provided to the citizens and the public notice parts but there is much less oversight on that part of the program.

Senator Clodfelter said he felt that EPA's primary interest should be in the quality of the water and not the accounting.

Mr. Givens asked what was problematic with the program.

Mr. Pierce said that the program was problematic in getting corrections through enforcement.

Ms. Miles said that 44 percent of the systems in 2004 had some kind of monitoring and reporting violation, failure to conduct the required testing. This is problematic in getting these systems to understand the requirements for testing and to do that on the frequency needed.

Ms. Miles said there is a higher level of contamination in larger systems now with the introduction of the disinfection byproduct rules.

Senator Clodfelter asked Ms. Miles if the contamination rate is six percent.

Ms. Miles said that six percent have some exceedance of a maximum contaminant level standard.

Senator Clodfelter asked Ms. Miles if the episodes were isolated or were they repeat offenders.

Ms. Miles said that for the contaminant based standards; it would tend to be repeat offenders. For monitoring violations, there are ones who forget an occasional sample and very chronic non-compliers who haven't taken a sample for years and are tied up in the Attorney General's office and the court system.

Senator Clodfelter asked Ms. Miles if we target whatever federal or state assistance might be available for corrected action and is it targeted to those repeat offenders.

Ms. Miles said that it is not targeted to repeat offenders; they basically keep up with the minimum requirements and don't have the resources to go back later and provide targeted effort.

Mr. Pierce continued his report on radiation protection. He said that the role of the Radiation Protection Section (RPS) is authorized by the Radiation Protection Act to consult, advise and cooperate with public and private agencies to respond to any emergency, which involves a possible actual release of radioactive materials.

Mr. Pierce said that the RPS monitors and inspects facilities from nuclear power plants to tanning beds and x-ray units as well as homeland security issues.

Mr. Pierce said that RPS's role is to provide advice to the incident commander and first responders in order to protect them from unnecessary radiation hazards.

Mr. Pierce added that RPS's goal is to provide education to law enforcement and first responders to assist them in performing their duties in a safe manner.

Mr. Pierce said that the Onsite Wastewater Section (OWS) established the Innovative and Experimental On-site Systems Committee in January 1999.

Mr. Pierce said the innovative systems are those approved for use by the Department. Accepted systems are those who have had a good track record for five or more years.

Mr. Pierce said that the Chamber Trench Systems and the Polystyrene Aggregate Trench Systems are currently being considered for the accepted status.

Mr. Pierce said that control demonstrations are systems that have no track record in North Carolina and may or may not have it in another state and are approved by the Department for testing or trial under actual field conditions in the State.

Mr. Pierce said that the Division is currently performing a survey to determine how the two systems compare to a conventional system.

Senator Clodfelter asked Mr. Pierce how tire chips work as an innovative wastewater system.

Mr. Pierce said that tire chips are used as an aggregate in lieu of stone.

Mr. Pierce said that experimental systems are developed to research new ideas and have no track record and must undergo further testing before being considered as an innovative system.

Mr. Pierce said that Peat On-Site Systems are primarily used on the coast. The coastal soils allow the advantage of being able to install a bed type system that is directly beneath the peat modules.

Mr. Pierce said the peat systems are the most frequently used treatment system. There are now over 300 systems currently in use.

Mr. Pierce said that the Studies Act of 2004 mandated that the State evaluate the desirability and feasibility of developing and implementing a pilot program prescribing the use of innovative peat based wastewater systems.

Mr. Pierce said that the on-site wastewater section is currently working with the Commission for Health Services to develop recommendation for the legislature.

Mr. Pierce said that the peat systems have encountered some problems such as fire ant infestation, which makes the operation maintenance difficult and causes damage to the peat.

Mr. Pierce said that while these problems exist, the Commission for Health Services has established a subcommittee to complete the mandated evaluation of the General Assembly and to review the rulemaking petition. The subcommittee will consider the desirability and feasibility of the revision and adoption of new rules and report the findings and recommendations to the Commission for Health Services at the February 2005 meeting.

Senator Dorsett asked Mr. Pierce if there is a formal relationship between the state and local governments as it relates to homeland security and if so, what is that relationship.

Mr. Pierce said that the Radiation Protection Section does not do that.

Senator Clodfelter told Senator Dorsett that he believe the Division of Crime Control and Public Safety has overall responsibility for coordinating the State's interaction of local governments with regard to homeland security.

Senator Horton asked Mr. Pierce how many employees the Division of Environmental Health has.

Mr. Pierce said the Division of Environmental Health employs 280 people.

Mr. James D. Simons, State Geologist and Director, Division of Land Resources (DLR), DENR, gave a follow-up presentation on the resources needed to expand the State Geologic Hazards Mapping Program. A copy of Mr. Simons presentation and a letter from Fred Allen, Executive Director of the North Carolina Aggregates Association, recommending additional appropriations for expanding the NCGS's Geologic Hazards Program, are listed as **Exhibit F**.

Mr. Simons said that he is proposing a hazard mapping program and database of geohazards throughout the State. This would provide public developers, local governments and state agencies a better database to make informed decisions with regard to building.

Mr. Simons said that landslides are not the only geohazards but the most dangerous and most prevalent one at the moment.

Mr. Simons said that they propose a five-year program but don't expect to have it solved in five year. The plan is to map several counties a year.

Mr. Simons said that DLR would cooperate and utilize to the extent possible the resources already available within the State. They plan to work with DOT and Emergency Management to pool resources.

Mr. Simons said that many of the mapping program costs are one-time costs. The costs would go down after the initial purchases of software to perform the actual mapping.

Senator Clodfelter said that the ERC doesn't often make recommendations on appropriations but it is within our statutory charge to do so.

Senator Clodfelter suggested to members that the information provided would be discussed among the co-chairs and a decision would be made as to whether this issue would be considered at one of the January 2005 meetings.

Mr. Simons gave a report on the programs, activities, and priorities of the Division of Land Resources. A copy of an outline of his presentation is listed as **Exhibit G.**

Mr. Simons said that North Carolina was the first state to have a State Geodetic Survey. It was authorized in the 1930s and became a reality in 1959.

Mr. Simons said that the geodetic survey is in great demand to share their knowledge with other professionals. Global positioning stations have been added to allow surveyors to better utilize the satellite surveying techniques currently available.

Mr. Simons said that North Carolina's geological survey is also the oldest in the nation, going back to 1825.

Mr. Simons said that since 1825, there have only been twelve state geologists and he has held the title for North Carolina for 30 years.

Mr. Simons said that North Carolina also produced the first state geologic map.

Mr. Simons said that one of the core jobs of the Geological Survey is geologic mapping. They have mapped approximately 215 square miles, primarily around the Triangle area and Asheville.

Mr. Simons said that subsurface mapping of the outer banks is being done in conjunction with the U.S. Geological Survey.

Mr. Simons said that the biggest challenge facing the geological survey is funding.

Mr. Simons said that the land quality section handles safety of dams, mine reclamation and erosion and sediment control.

Mr. Simons said that the field offices are cross-trained in all three programs. This also allows flexibility for shifting people from one end of the state to the other in the event of disaster such as the landslides from the hurricanes.

Mr. Simons said that a better database has been developed for the dam safety and mine sites and one for sediment control is being developed.

Mr. Simons said most of the mines in North Carolina are related to the construction industry. The number of permitted mines has tripled in the last 15 years although there is the same number of people with the mining program.

Mr. Simons said that there are approximately 8,000 active construction sites in the sediment control program.

Mr. Simons said there is a need for emphasis on preventing erosion rather than trapping sediment, and to improve current erosion and sediment control measures.

Senator Horton said he was concerned that a lot of good will can be squandered through the form letters currently being used. He asked Mr. Simons if he would review the form letters and make the necessary corrections to ensure that we are not judge and jury. He suggested saying "may" instead of "are".

Mr. Simons told Senator Horton that his point was well taken.

Representative Weiss asked Mr. Simons if he is suggesting we try legislation again in improving sedimentation.

Mr. Simons said that the sedimentation control commission did appoint a subcommittee to look at the amendments, starting with last year's bill. The subcommittee consists of members of the development, engineering and environmental communities.

Mr. Simons said they have come out with a recommendation to present to ERC. The most important thing that needs to be added is a sentence directing the developers to follow the approved erosion sedimentation control plan. Somewhere there is a quirk in the law that does not specifically state that. That minor fix would help immensely.

Mr. Simons said there are other issues such as self-inspection that would require the owner or its representative to report installation. Other suggestions would be to grant local programs to partial delegation.

Senator Clodfelter asked Mr. Givens if we have Mr. Simons' recommendations.

Mr. Givens said that he did not have any recommendations and asked Mr. Simons to provide him with the recommendations.

Senator Clodfelter asked Mr. Simons if there is enough demand for the mapping products that would warrant a higher fee schedule to expand the scope of the mapping and surveying activities.

Mr. Simons called on Mr. Tyler Clark, Chief Geologist for the State Geological Survey, who said there was a very high demand for geologic information. They typically receive inquiries on a daily basis for someone wanting a map for some portion of the state.

Mr. Clark said that only 14 percent of the state is currently mapped with detailed geologic mapping. There are regional maps available for the rest of the state. They could improve on the number of square miles covered if they could seek the grant funding to do that.

Senator Clodfelter asked Mr. Clark if they had every done a cost recovery study to figure out what kind of charges they may have to impose in order to recover the existing costs and what additional revenue could be generated to expand the mapping beyond the 14 percent.

Mr. Clark said they have just started to look into this to see what type of limitations they have on cost recovery for the products they produce. There are certain limits on what the public can be charged and what the market will bear.

Senator Clodfelter said that survey maps can be purchased in bookstores in the UK and this finances the whole mapping and survey system for the country.

Mr. Simons said there are some limitations for us to do this but that would certainly be looked into.

Mr. David S. Vogel, Director, Division of Soil and Water Conservation, DENR, gave an update on the identification and closure of inactive and abandoned animal waste management lagoons. A copy of his remarks given in his report is listed as **Exhibit H.**

Mr. Vogel said that 133 inactive lagoons have been closed since 2000, with an added 79 scheduled to be closed this program year. An added 56 operations have gone inactive since 2004 and 9 have been reactivated.

Mr. Vogel said that 36 percent of the high-risk lagoons are closed or are under contract to be closed.

Mr. Vogel said that lagoon closures are funded through the Agriculture Cost Share Program, USDA Environmental Quality Incentive Program, Smithfield Agreement/NC Foundation for Soil and Water Conservation, and the Clean Water Management Trust Fund (CWMTF).

Mr. Vogel said that after Hurricanes Floyd, Dennis and Irene, a new program was developed to purchase conservation easements and buyout certification for swine farms in the 100-year floodplain. There is a prohibition for putting new swine farms in the 100-year floodplain and this program was developed as a voluntary option for those landowners impacted by flooding to get out of the business.

Mr. Vogel said that this program is focused on active farms.

Mr. Vogel said that two phases of funding have been approved by the CWMTF totaling $12 million. They have gone through closing operations on 32 lagoons, on 15 farms in Phase I. In Phase II, there are 30 lagoons on another 15 farms that are being worked on.

Mr. Vogel said that approval has been received from the trustees of the CWMTF for a third phase of funding and they are awaiting a contract for another $3.9 million.

Mr. Vogel said that they have been able to tap into some of the federal farm bill funds to help close some of the lagoons. That allows the use of state money toward conservation easements for the landowners.

Mr. Vogel said the standard for closing a lagoon is a federal USDA standard. The Natural Resource Conservation Service (NRCS) has a standard for closing of waste lagoons, which is what everyone uses in North Carolina.

Mr. Vogel said the local Soil and Water Conservation District or a technical specialist that is certified by the Soil and Water Commission closes the lagoons under a lagoon closure plan as developed.

Mr. Vogel said the NRCS standard was changed a few years ago to allow some alternative lagoon closure methods.

Mr. Vogel said the nutrient management standard has changed with regard to land application.

Mr. Vogel said that it is costly to close a lagoon. The cost in 2000 was $42,000 per acre. With the buyout, the cost has been reduced to $34,000 per acre.

Mr. Vogel said that with the phosphorous requirements, they are beginning to see the costs go up for a lagoon closure.

Mr. Vogel said that it is estimated that it will take $1 million to complete closure of the remaining 26 high-risk lagoons.

Mr. Givens asked Mr. Vogel what the terminology is for an inactive lagoon.

Mr. Vogel said that an inactive lagoon is one that has not received waste for one year.

Mr. Givens asked Mr. Vogel how many of the 1,000 inactive lagoons have a responsible party that can close them or would the state have to close all of them.

Mr. Vogel said it was his understanding that for sites that are under permit, the permittee has to maintain the lagoon even if it is no longer in production.

Mr. Givens asked how many of these lagoons are going to be closed by the people who own them and how many are going to be closed through some combination of state funding.

Mr. Vogel said that they would either have to be closed or maintained.

Mr. Givens asked how many of them are abandoned or orphaned in the sense that there is no permit holder or the permit holder is noncompliant.

Mr. Vogel said that he believed it would be a small number.

Mr. Givens asked on average, how much it cost to close a lagoon.

Mr. Vogel said that for the buyout, they are spending about $84,000 to close a lagoon.

Mr. Givens said that he would like to work with Mr. Vogel to receive more information regarding lagoon closures and costs involved.

Senator Albertson asked Mr. Vogel if the owner of a permit is responsible for maintaining the integrity of a lagoon, regardless of whether it is in operation.

Mr. Vogel said this was correct.

Mr. Givens asked Mr. Vogel to provide him with the projection for future inactive lagoons, how many of the lagoons already in the system will have to be closed at state expense and at what cost, and how many owners and operators cannot comply with the requirements.

Representative Weiss ask every single lagoon that is closed is eligible to have cost sharing and would only be paying a maximum of 25 percent of the cost.

Mr. Vogel said the only restriction on the state side is the Soil and Water Commission will not use cost share money to close a lagoon but will use money to construct new ones.

Mr. Givens said if it was cost-share constructed, then someone else would have to pay for closure.

Mr. Givens asked Mr. Vogel what the annual cost for a permit is.

Mr. Paul Sherman, Division of Water Quality, answered Mr. Givens by saying the cost ranges from $50 to $300. For most of the facilities that have inactive lagoons the permit fee would be $50.

Mr. Vogel said that when the state permits shifted to NPDES, they anticipated more requests for lagoon closures.

Senator Albertson asked Mr. Vogel if an inactive lagoon is inspected twice a year as active lagoons are.

Mr. Vogel said that the inactive lagoons do not get the level of inspection that active lagoons do.

Senator Clodfelter asked Mr. Vogel what level they do get.

Mr. Sherman answered by saying that if the inactive lagoon is covered under a permit, the Division of Water Quality does a compliance inspection once a year.

Mr. Vogel said that the Division does not do its operation reviews on inactive farms.

Representative Gibson asked if it was fair to say that the inspectors know where most all of the inactive lagoons exist.

Mr. Sherman answered by saying that they have a good idea of where all of them are, based on the 2000 survey. As far as the percent inspected each year, he was not prepared to give an answer.

Representative Gibson asked if most of the inactive sites had been dewatered.

Mr. Givens said that any of these sites would accumulate water because of rainfall.

Senator Horton asked what would happen if a lagoon was left unattended.

Mr. Vogel said that maybe nothing would happen; however, it is a structure that has the potential to breech if the lagoon walls are not managed. Some of them have to be pumped because they accumulate.

Senator Horton asked what the worst-case scenario is with a lagoon.

Mr. Vogel said that a breech is the worst-case scenario.

Senator Horton asked what the consequence would be.

Mr. Vogel said that nutrients would be added to groundwater.

Representative Gibson said that he believes DENR has done a good job with these inactive sites and should be commended.

Mr. William D. Gilmore, Director, Ecosystem Enhancement Program, DENR, gave a report on implementation of the Wetlands Restoration Program (Ecosystem Enhancement Program) and use of funds in the Wetlands Restoration Fund. A copy of his slide presentation and a one sheet executive summary are listed as **Exhibit I**.

Mr. Gilmore said that the Ecosystem Enhancement Program has been in existence about 17 months. A program advisory group under the Wetlands Restoration program and a program assessment and consistency group under the DOT program are watching the program from a regulatory standpoint.

Mr. Gilmore said that one issue with the program has been in expediting their capacity.

Mr. Gilmore said that EEP does not do any in-house work and everything is done through private enterprise.

Mr. Gilmore said that no independent wetland projects were produced last year; however, there were a number of projects where wetland and stream restoration were combined.

Mr. Gilmore said the existing rates for non-riverine restoration appear to be appropriate. They are seeing an escalation for the riverine wetland systems.

Mr. Gilmore said that the Wetlands Trust Fund Restoration Account currently has $75,315 and the Compensatory Mitigation Account has $29,194,488. The Riparian Buffer Restoration Account has a balance of $10,004,576.

Mr. Gilmore summarized by saying that the program has grown, there have been a number of visitors to the program, and production has been increased.

Mr. Gilmore said that next year, they would be working with the regulatory committees and groups to meld a comprehensive report showing the entire status of the Ecosystem Enhancement Program.

Representative Gibson asked Mr. Gilmore to provide information for ERC members on what was done to increase the number of permits in the last year.

Mr. Gilmore said the best thing would be no need to have permits. As a general trend there are a couple of new responsibilities they are accepting under the program. They are providing impacts for Corps of Engineers permits and there has been some significant activity in nutrient offset with the Division of Water Quality.

Representative Gibson asked Mr. Gilmore if it is fair to say that we are still seeing the majority of dollars going to road projects.

Mr. Gilmore answered in the affirmative.

Representative Gibson asked for a matrix showing a trend.

Representative Gibson asked Mr. Gilmore to give us the high spots of the program and the low spots that may need correcting.

Suzanne Klimek, Director of Operations for EEP, said they have a very good relationship with the Corps of Engineers and the compliance rate is increasing.

Representative Gibson asked Mr. Gilmore to provide a snapshot of how we did it before and how we can do it better in the future and if we are still using the same techniques for restoration.

Ms. Klimek said that there were no new completed wetlands restoration projects to add to the cost evaluation for this last fiscal year.

Representative Gibson asked Ms. Klimek if $100,000 for design on a $600,000 project and $123,000 for design on a $500,00 project the best we can do or have we reached the zenith of cost savings.

Ms. Klimek said she did not have the answer to his question but she could say the program works consistently to manage costs through their projects.

Representative Gibson asked if it was fair to say in a comparable state managed program that we were close.

Ms. Klimek said she thought we were lower in comparison.

Representative Gibson asked Mr. Gilmore if the drop in the number of projects completed last year was due to a bad year.

Mr. Gilmore said he believed it was because of where they fell in the cycle. There are some projects in production, which take two to three years to complete.

Representative Gibson asked Mr. Gilmore to provide where we are today as a cost per unit.

Mr. Gilmore said he would get this information to staff.

Mr. Givens added that he hoped Mr. Gilmore would come forward with the information on cost of roads and scheduling and completion of road projects.

Representative Gibson added Mr. Gilmore to include the forecast on where we need to go to do better.

Mr. Gilmore said that his program does have a forecasting tool, which comes from the Department of Transportation. They will provide a seven-year forecast on February 1, 2005. You will see the Wetlands Restoration Program dollars come down over the years. The funds will change to the DOT program.

Mr. Givens said this is a scheduled agenda item for the 20 January 2005 meeting.

Mr. Donnie D. Redmond, Assistant Chief, Planning Section, Division of Air Quality, DENR, gave a report on air quality issues and innovative approaches to reduce air pollution from mobile sources.

Mr. Redmond's report included information on the modification of the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle, and information on modification of the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicles is based on the vehicle miles traveled by the vehicle. A handout outlining his report is listed as **Exhibit J**.

Senator Clodfelter said that the next two presentations are topics for potential study and came from a serious of ad hoc public meetings the Senate had on mobile source air pollution and water conservation issues.

Mr. Redmond said that North Carolina currently charges a three percent tax on new and used vehicles when they are purchased. The idea behind this item would be to get people to buy more fuel-efficient vehicles.

Mr. Redmond said that the second item was to look at the annual vehicle registration fee to see if it should be changed based on how much the car is driven each year. The standard fee is $20 a year. Cars driving more a year would pay a higher registration fee each year than those that are driven fewer miles.

Mr. Redmond said that the third item is to look at both of these fees and determine whether they should be revenue neutral or revenue generated from the fees.

Mr. Redmond said that research is currently being done and a final report is expected by January 2005.

Senator Albertson asked Mr. Redmond if this would unnecessarily affect the lower income people.

Mr. Redmond said that they may be buying the lighter, more fuel-efficient care and would more likely be receiving a rebate.

Senator Dorsett said it would be useful if there were some consumer or focus groups to get their feedback before they complete their report.

Representative Weiss said that she would like to see what impact it would have on lower income folks. She also said she thought they should look beyond AAA and look at folks who advocate for people with low incomes.

Representative Weiss said that she would also like them to consider putting this into a Clean Air Trust Fund where people could apply for grants.

Mr. Givens said that one of the items to be studied by ERC is a Clean Air Trust Fund. He hopes there will be an agenda item on this in January 2005.

Mr. Larry E. Shirley, Director, State Energy Office, Department of Administration, gave a report on the expansion of the guaranteed energy savings contracts program to include contracts that provide for the conservation of water and sewer usage. A copy of Mr. Shirley's slide presentation is listed as **Exhibit K.**

Mr. Shirley said that the state has a major initiative underway now called the Utility Savings Initiative to try and save energy and water costs in state and university buildings.

Mr. Shirley said this is an outgrowth of the Governor's Efficiency Commission in 2002 and has a goal of four percent reduction in energy consumption each year for the next five years, adjusted for increases in fuel prices and square footage.

Mr. Shirley said that strategic utility plans are required and we now have 96 percent of the state's square footage underneath a plan of some kind or another.

Mr. Shirley said that they have run into poor accounting practices in the state in the sense that we have not had a handle on how much we were spending on water or energy.

Mr. Shirley said that one program within this initiative is called guaranteed energy savings contracts, often referred to as performance contracting.

Mr. Shirley said that we have been trying to include water in the efforts. Looking at the State Government's water usage, we spend about $28.5 million each year and consumer 15.6 million gallons per day.

Mr. Shirley said that sewer costs now include stormwater fees.

Mr. Shirley said that DENR and Crime Control and Public Safety have been charge with a lot of the training in the performance contracting. The drought brought about HB 1215, which mandated a 10 percent reduction in water use in state facilities.

Mr. Shirley said that the Governor also mandated Executive Order 26, which banned nonessential use of water. Water plans have been required of the agencies and submitted to DENR.

Mr. Shirley said there have been some major successes in state government with regard to water billing refunds and errors. DHHS and NC A&T both found billing errors totaling $135,000.

Mr. Shirley said that the North Carolina Zoo has saved $200,000 per year just by installing a sewer meter so they are not charged for the water they use that does not go into the sewer.

Senator Clodfelter asked Mr. Shirley if municipalities allow this or was this optional.

Mr. Shirley said this is negotiated on a case-by-case basis.

Senator Horton asked Mr. Shirley to explain how a sewer meter works.

Mr. Shirley asked Mr. Vince Throop, Program Manager, Utility Savings Initiative to answer that question.

Mr. Throop said that the way sewer charges are done is through the water meter reading. With the sewer meter, you can put a special meter in your sewer line to actually measure what goes down the sewer and then negotiate with the water utility to charge for that.

Mr. Shirley said that a law was passed in 2002, which allowed the State to engage in performance contracting or guaranteed energy savings contracts. The bill was amended in 2003 and the rules were written thereafter.

Mr. Shirley said that there are no upfront capital costs involved. The state started with setting a $50 million limitation on what could be put out in the way of contracts with 12-year maximum contracts.

Mr. Shirley said that the state's water bill is about 11 percent of the total state utility bill of $256 million.

Senator Clodfelter asked if this was just a savings for the State and did not include local governments.

Mr. Shirley said this was correct.

Mr. Shirley said that the recommendations are to amend the statute that governs these guaranteed savings contracts to specifically include water saving measures, to increase the cap from $50 million to $75 million, or remove the cap altogether.

Mr. Shirley said they also recommend including water measures in the general statutes, to make sure that when we approach this issue, we approach energy and water together.

Representative Hackney asked Mr. Shirley to tell about the gray water project at UNC-Chapel Hill at the power plant and the projected savings.

Mr. Shirley said he was not aware of what the projected savings are. Chapel Hill is using gray water in their co-generation plant. Chapel Hill generates about one-third of its electricity from a co-generation plant. They have been able to use gray water.

Senator Clodfelter asked how this project is being financed and could we use this financing technique to make it easier for others to do similar projects.

Representative Hackney said that he did not have an answer.

Senator Albertson asked what the reason was for the wide variation in what water users pay.

Senator Clodfelter said that the largest part of the reason is that most large water systems are municipally owned and operated in North Carolina and are not subject to rate regulation in any way.

Mr. Shirley said that one example is UNC-Pembroke, whose water bill rate is ten times what the state average is, by municipality.

Representative LaRoque asked Mr. Shirley if the $50 million contract money we are spending to find out the efficiencies or the savings.

Mr. Shirley said the $50 million is the total contracting authority that the State of North Carolina can enter into with the exception of finance costs. There are two different ways to finance these projects, both at the State Treasurer's discretion.

Mr. Shirley said the State Treasurer can issue certificates of participation (COPS) to finance the project or the energy service company can come to the table with financing.

Senator Clodfelter if the contractor has to guarantee the savings.

Mr. Shirley said the contractor has to guarantee the savings and most have some security instrument acceptable to the State Treasurer.

Representative LaRoque asked what the minimum rate of return to the taxpayer.

Mr. Shirley said that the contracts have to be within a twelve-year period. A lot of expensive items such as boilers and chillers need to be replaced and their actual payback is a longer return.

Representative LaRoque asked if there was a minimum rate of a 6 percent rate of return over 12 years for this to come to parity.

Mr. Shirley said this was correct.

Senator Dorsett asked if the savings are guaranteed and they don't meet the standards, what are the conditions for termination.

Mr. Shirley said that if they don't meet the savings, they have to write the state a check.

Mr. Throop said that he believed that the contract could be cancelled if the standards are not met.

Representative Hackney said that the savings are supposed to survive the contract.

Representative Gibson asked Senator Dorsett if she had a perspective on this.

Senator Dorsett said she believes it is an excellent beginning.

Senator Clodfelter asked Mr. Shirley to work with Mr. Givens on some of these recommendations to be presented at the 25 January 2005 meeting.

The meeting was adjourned at 1:15 p.m.

Senator Daniel Clodfelter
Presiding Co-Chair

Mary R. Watson
Commission Clerk

RE: **Notice of Commission Meeting**
Notice of Planning Meeting
Schedule of Future Meetings
Meetings of Interested Parties (605 Working Groups)
Additional Information

COMMISSION MEETING:

The Environmental Review Commission (ERC) will meet at 9:30 a.m. Tuesday 7 December 2004 in Room 544 of the Legislative Office Building in Raleigh. At this meeting, the ERC will begin or continue studies for which the ERC is responsible, hear reports from State agencies, discuss topics to be considered at future meetings, and attend to other matters. Listed below are potential agenda topics for this meeting and for future meetings. More specific information regarding the agenda for the 7 December meeting of the ERC will be developed at the staff planning meeting discussed below.

STUDY TOPICS:

Air Quality:

1) Modification of the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle (S.L. 2004-161, Sec. 19.10(1))

2) Modification of the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle (S.L. 2004-161, Sec. 19.10(2))

Miscellaneous:

3) Effectiveness of the State's efforts to protect the environment and conserve the natural resources of NC (S.L. 2004-161, sec. 19.2)

4) Development of a plan to share floodplain mapping information (S.L. 2004-161, Sec. 19.3)

5) Efforts to stimulate renewable energy production in the State

6) Issues related to water and sewer infrastructure in the State and resources needed to maintain and upgrade the infrastructure systems

7) Results of the conservation needs assessment conducted by the Land for Tomorrow Coalition

Water Quality:

8) Approaches to prevent and reduce stormwater pollution throughout the State (S.L. 2004-161, Sec. 19.11)

9) Issues related to the Leaking Petroleum Underground Storage Tank (UST) Cleanup Program (S.L. 2003-352, Sec. 12)

10) The role of the State and DENR in implementing the Leaking UST Cleanup Program (S.L. 2004-124, Sec. 30.10.(f)) (joint study with the Joint Legislative Transportation Oversight Committee)

11) Identification and closure of inactive or abandoned animal waste management lagoons

12) Issues related to the proposed permit modification for the John Umstead Wastewater Treatment Plant located in Butner, and the associated adjustment of its effluent limitations for Total Nitrogen to reflect the purchase of nitrogen allocations

Water Quantity:

13) Water restriction guidelines created by DENR and implemented by local governments, including an evaluation of economic impacts and recommendations for establishing consistency across the State with respect to classes of water use (S.L. 2004-161, Sec. 19.4)

14) Development and funding of regional water supply systems (S.L. 2004-161, Sec. 19.5)

15) Water conservation measures being implemented in the State and incentive programs and other voluntary programs that can help foster water conservation and reuse

16) Expansion of the guaranteed energy savings contracts program for governmental units to include contracts that provide for the conservation of water and sewer usage

REPORT TOPICS:

Air Quality:

17) Annual report on development and implementation of a plan to reduce vehicle miles traveled by private sector employees and vehicle emissions resulting from job-related travel, including commuting to and from work (G.S. 143-215.107C(e))

18) Annual report on development and implementation of a plan to reduce vehicle miles traveled by State employees and vehicle emissions resulting from job-related travel, including commuting to and from work (S.L. 1999-328(4.6))

19) Annual report on promotion of telework/telecommuting for State employees and achieving the goal of reducing State employee vehicle miles traveled in commuting by 20% without reducing total work hours or productivity (S.L. 1999-328(4.8))

Parks and Recreation / Land Conservation:

20) Parks and Recreation Trust Fund Annual Report, Fiscal Year 2003-2004 (G.S. 113-44.15(c))

21) North Carolina Natural Heritage Trust Fund Award Report, Fiscal Year 2003-2004 (G.S. 113-77.9(e))

22) Annual report on progress towards attaining the State's goal of protecting one million acres of farmland, open space, and conservation lands (G.S. 113A-241(c))

23) Annual report on implementation of the Conservation Easements Program and inventory of all conservation easements held by DENR (G.S. 113A-235(c))

Water Quality:

24) Issues related to the evaluation of alternative animal waste management technologies to determine whether those technologies are environmentally superior and economically feasible

Wetlands:

25) Implementation of the Wetlands Restoration Program and use of funds in the Wetlands Restoration Fund (G.S. 143-214.13)

PLANNING MEETING:

To facilitate development of the agenda for the 7 December meeting of the ERC, to plan for subsequent meetings of the ERC, and to receive input from interested persons regarding the work of the ERC, the Commission Counsel will hold an informal planning meeting at **10:00 a.m. on Wednesday 1 December 2004 in Room 605 of the Legislative Office Building**. Persons who wish to participate in the development of the agenda for meetings of the ERC, or who are interested in any matter before the ERC, are invited to attend.

SCHEDULE OF FUTURE MEETINGS:

Below is a schedule of meetings of the ERC for January 2005. This schedule is tentative and subject to adjustment. For planning purposes, please reserve these dates.

Commission Meeting	**Staff Planning Meeting**
Wednesday 12 January 2005	Wednesday 5 January 2005
Thursday 13 January 2005	
Thursday 20 January 2005	
Tuesday 25 January 2005	

MEETINGS OF INTERESTED PARTIES (605 WORKING GROUPS):

The Commission Counsel will hold meetings of interested parties on specific topics as indicated below:

Limit Liability for Environmental Cleanups Working Group (HB 1603/SB 1222)
10:00 a.m. Thursday 2 December 2004 – 605 Legislative Office Building

ADDITIONAL INFORMATION:

If you have questions related to the Commission, please feel free to contact the Commission Counsel or other Commission staff at (919) 733-2578.

AGENDA
9:30 a.m. Tuesday 7 December 2004
Room 544 Legislative Office Building

1. Call to order
   Senator Daniel G. Clodfelter, Presiding

2. Introductory remarks by Cochairs
   Senator Daniel G. Clodfelter
   Senator Charles W. Albertson
   Representative Pryor A. Gibson
   Representative Daniel F. McComas

3. Report to the Commission and explanation of agenda items
   George F. Givens, Commission Counsel

4. Follow-up discussion of the resources needed to phase-in a statewide expansion of the Wastewater Discharge Elimination Program
   Terry L. Pierce, Director
   Division of Environmental Health, Department of Environment and Natural Resources (DENR)

5. Report on the programs, activities, and priorities of the Division of Environmental Health
   Terry L. Pierce, Director
   Division of Environmental Health, DENR

6. Follow-up discussion of the resources needed to expand the State Geologic Hazards Mapping Program
   James D. Simons, State Geologist and Director
   Division of Land Resources, DENR

7. Report on the programs, activities, and priorities of the Division of Land Resources
   James D. Simons, State Geologist and Director
   Division of Land Resources, DENR

8. Update on the identification and closure of inactive and abandoned animal waste management lagoons

   David S. Vogel, Director
   Division of Soil and Water Conservation, DENR

9. Annual report on implementation of the Wetlands Restoration Program (Ecosystem Enhancement Program) and use of funds in the Wetlands Restoration Fund (G.S. 143-214.13)

   William D. Gilmore, Director
   Ecosystem Enhancement Program, DENR

10. Discussion of air quality issues and innovative approaches to reduce air pollution from mobile sources

    Modification of the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle (S.L. 2004-161, Sec. 19.10(1))

    Donald D. Redmond, Assistant Chief
    Planning Section, Division of Air Quality, DENR

    Modification of the current vehicle registration fee so that all or a portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle (S.L. 2004-161, Sec. 19.10(2))

    Donald D. Redmond, Assistant Chief
    Planning Section, Division of Air Quality, DENR

11. Information item on the expansion of the guaranteed energy savings contracts program to include contracts that provide for the conservation of water and sewer usage

    Larry E. Shirley, Director
    State Energy Office, Department of Administration

12. Commission discussion and announcements

13. Adjourn

SCHEDULE OF FUTURE MEETINGS:

Below is a schedule of meetings of the Environmental Review Commission for January 2005. This schedule is tentative and subject to adjustment. For planning purposes, however, please reserve these dates.

Wednesday 12 January 2005	Joint meeting with Joint Legislative Commission on Seafood and Aquaculture
Thursday 13 January 2005	Regular business meeting
Thursday 20 January 2005	Joint meeting with Joint Legislative Transportation Oversight Committee
Tuesday 25 January 2005	Regular business meeting; consideration of legislative proposals (tentative)

STAFF PLANNING MEETING:

To facilitate development of the agenda for the January meetings of the ERC, the Commission Counsel will hold an informal public staff planning meeting at **10:00 a.m. on Wednesday 5 January 2005 in Room 605 of the Legislative Office Building**. Persons who wish to participate in the development of the agenda for meetings of the ERC, or who are interested in any matter before the ERC, are invited to attend.

OTHER MEETINGS:

The Commission Counsel will hold meetings of interested parties on specific topics as indicated below:

Limit Liability for Environmental Cleanups Working Group (HB 1603/SB 1222)
10:00 a.m. Friday 7 January 2005 – 605 Legislative Office Building

Wastewater Discharge Elimination Program (WaDE)

Program Update from Nov. 19 ERC Meeting

December 6, 2004

Terry Pierce, DEH Director

Highlights

- Purpose
- Goals
- Collaborative efforts
- 2001 Expansion
  - CWMTF and EPA grants
  - Hired new staff
  - Stats and Figures

Future Directions

- Geographical Scope
  - Currently serves 26 western counties
- Impact of straight-piping seen across N.C.
  - Public health
  - Environmental impact

Expanding WaDE Statewide

	Currently for 22 Counties (annually)	Expanded to 100 Counties (annually)
Appropriations:	$126,488	$574,854
CWMTF Grant:	$149,000	$677,419
EPA 319 Grant:	$166,656	$757,527
TOTALS:	**$442,144**	**$2,009,800**

Questions?

Terry Pierce, Director

Division of Environmental Health

Update for the Environmental Review Commission

Dec. 7, 2004

Terry Pierce,
Division Director

DEH Sections

- Environmental Health Services (EHSS)
- Onsite Wastewater (OSWW)
- Public Health Pest Management (PHPM)
- Public Water Supply (PWS)
- Radiation Protection (RPS)
- Shellfish Sanitation and Recreational Water Quality (SS&RWQ)

Environmental Health Services Section

Meth Labs

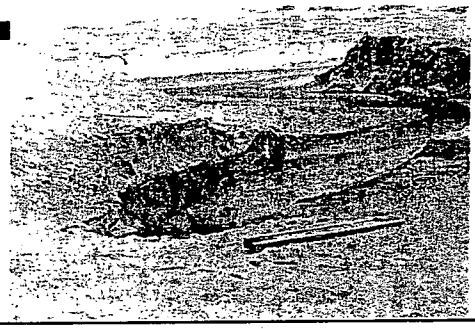
- New rules effective Jan. 1, 2005
  - Limited LHD involvement required
- Assistance from DEH
  - DEH, PHRST Teams, SOP, other divisions meet and discuss roles
  - Resource, info on waste disposal, onsite and public sewage disposal, groundwater contamination
  - Optional investigations by LHD
- Staff safety
  - Lead investigations
  - Hotel & motel inspections

Shellfish Sanitation & Recreational Water Quality Section

Stormwater: Basics

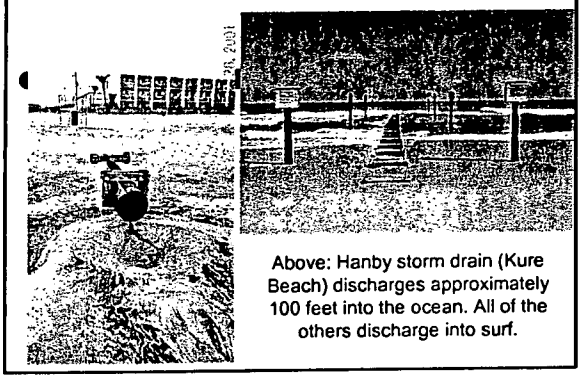
- Relates to shellfishing and recreational waters
- Outfalls directly onto beaches or into ocean
- Affects all shellfish growing area waters and interior recreational waters
- Causes
  - Development
  - Impervious surfaces

Stormwater Drains



Stormwater: Impact

- County impact
  - Ex: Brunswick and New Hanover Counties have more than 50 percent of shellfish waters closed.
- Loss of revenue
  - Shellfish harvesters
  - Local economy
- Increased development + increased stormwater = increased contamination

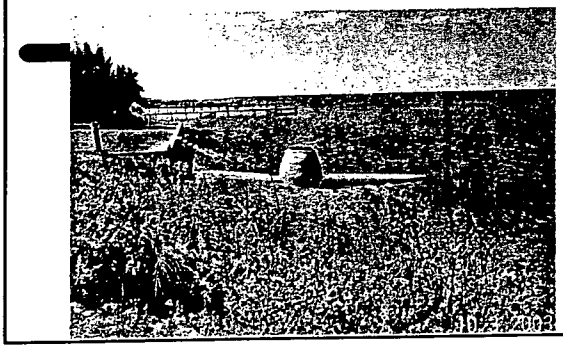


Above: Hanby storm drain (Kure Beach) discharges approximately 100 feet into the ocean. All of the others discharge into surf.

Stormwater: Shellfish Waters

- Of the 2.1 million acres of potential shellfishing waters, 365,000 are closed.
  - Approximately 18 percent of shellfish waters are closed.
- Conditional management of shellfish waters.
- Impervious surfaces from coastal development increases the stormwater into the shellfish waters.
  - Interferes with the natural processes to clean stormwater

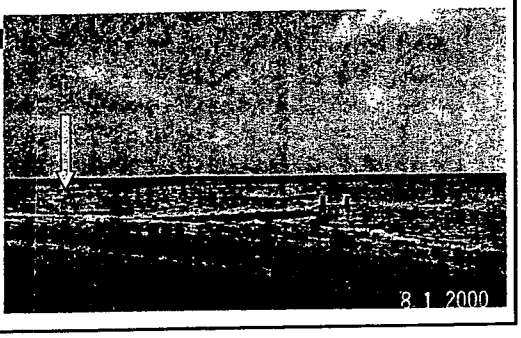
Sound-side storm drain to ORW and SA shellfish waters



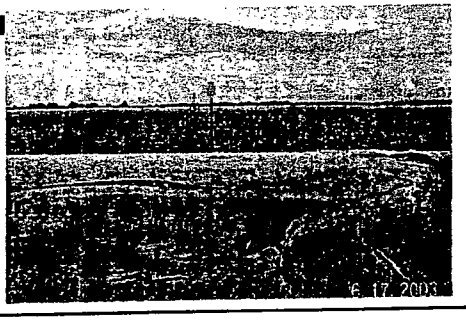
Stormwater: Recreational Waters

- Affected areas
  - Internal waters
  - Sound-side beach areas with little tidal exchange
  - All ocean storm drains that discharge to the surf
- Interagency efforts to assess storm drain issues
  - Stormwater (Rule) Work Group
- Future solutions
  - Remove storm drains from oceans whenever possible.

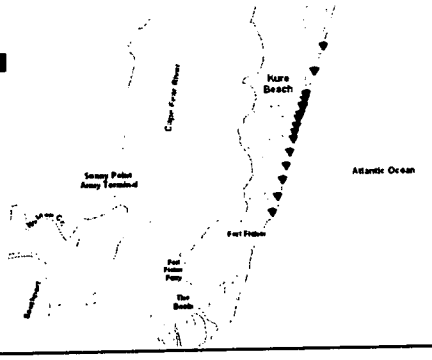
People swim beside storm drains.



Radio Island swimming area



GIS Mapping of
Storm Drain Discharge



Stormwater Work Group

- Cape Fear Council of Govts.
- Outer Banks Business Bureau
- Town of Kure Beach
- Town of Emerald Isle
- Town of Nags Head
- Town of Kill Devil Hills
- UNC Institute of Marine Sciences
- NC Coastal Federation
- UNC Coastal Studies Institute
- Pier Owner, Emerald Isle
- Commission for Health Services
- Environmental Mngmt. Commission
- NCDENR, DEH
- DEH Shellfish & Rec. Water Quality
- DHHS, Div. of Public Health
- Div. of Water Quality
- N.C. DOT Roadside Env. Ops
- N.C. DOT Division I County Maintenance/Currituck & Dare Counties
- N.C. DOT Hydraulics Project Engineer for Maintenance Studies
- N.C. DOT State Hydraulics Engineer
- N.C. DOT Project Engineer for Storm Water & Preliminary Studies

Public Water Supply Section

Public Water Supply

- Mission
- Program components
  - 6 basics
- Multi-barrier approach to protecting public health

Public Water Supply: Protection

- Protection the sources of drinking water
- Protection programs
  - Site investigations and approvals
  - SWAP
  - Wellhead protection

Source Water Assessment Program (SWAP)

- Purpose
- SWAP Info
  - Web site:
    - www.deh.enr.state.nc.us/pws/SWAP
  - Aspects
- Future Uses
  - Local planning and educational outreach tool

Public Water Supply: Treatment

- Treatment
  - Tightening federal standards ratcheting down- puts compliant systems out of compliance
  - Simultaneous compliance – tough to hit and operate on such a tight mark.

Public Water Supply: Testing/Monitoring

- Violations – unresolved issues
- Database management system – SDWIS
- Honor system implementation
  - Problems
- Public education for transient systems
  - Brochure for churches
- Formal enforcement
  - Issues: resource intensive, slow, lack of strong incentives to comply

Public Water Supply: Planning

- Risk management
  - Drought, limited supply, back up power
- Asset management
  - Who should pay?
  - Sufficient infrastructure investment
- Water system security

Radiation Protection Section

Homeland Security

- Role of Radiation Protection
  - Respond
  - Technical Assistance
- Dirty Bomb Exercise
  - Objective: to test the State Government Infrastructure Security Plan
  - Assist with scenario development and provide participants for exercise deployment

Onsite Wastewater Section

Innovative and Experimental On-site Systems

- Establishment of I&E Committee – Jan. 1999
  - 11 Volunteer Members
- Web site
  - www.deh.enr.state.nc.us/oww
  - All system approvals located on-line.

Innovative Systems: Description

- Must perform equal to or better than a system in the on-site wastewater rules.
- Materials must follow guidelines dictated in the rules with respect to physical properties and chemical durability.
- Able to withstand loads and conditions as required by the rules

Examples of Approved Innovative Wastewater Systems

- Drip Irrigation
- Chamber Trench Systems
- Tire Chips
- Multi-Pipe Systems
- Polystyrene Aggregate Trench Systems
- Sand Filter Pretreatment Systems
- Peat Filter Pretreatment Systems
- Trickling Filter Systems

Examples of Approved Innovative Wastewater Components

- Polyethylene Septic and Pump Tanks
- Fibermesh Reinforced Tanks

Experimental Systems: Description

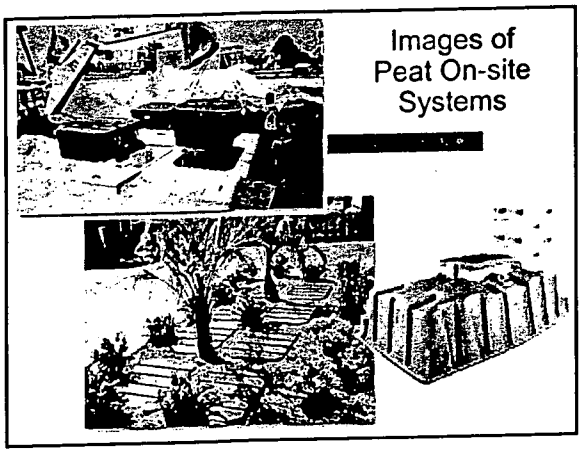
- Needs third party testing as a research project
- Reasonable likelihood of meeting project objectives
- Once the State determines that the standards of an innovative system have been met, the system will be removed from the experimental status and approved as an innovative system

Examples of Approved Experimental Wastewater Systems

- Wetlands Research Project
- High Organic Wastewater Pretreatment
- Sand Filter Modular Design Research Demo

Peat On-site Systems

- Two approved Peat systems:
  - Bord na Mona's "Puraflo" system
    - approved for use as Innovative in 1998
  - Premier Tech Environment's "Ecoflo"
    - approved for use as Innovative in 2000



Monitoring and Maintenance

- Owners of these peat systems must have an operator
  - At least 2 visits per year
  - Must be available to handle incidental needs.
  - Includes sampling of effluent annually

Problems and Issues

- Consistently meeting the effluent performance standards.
  - Causes
    - excessive flows
    - high strength wastewater
    - representative sample
- Operators not providing appropriate operation and maintenance services.
- Fire ant infestations

Questions?

December 7, 2004 ERC Meeting
EXHIBIT F

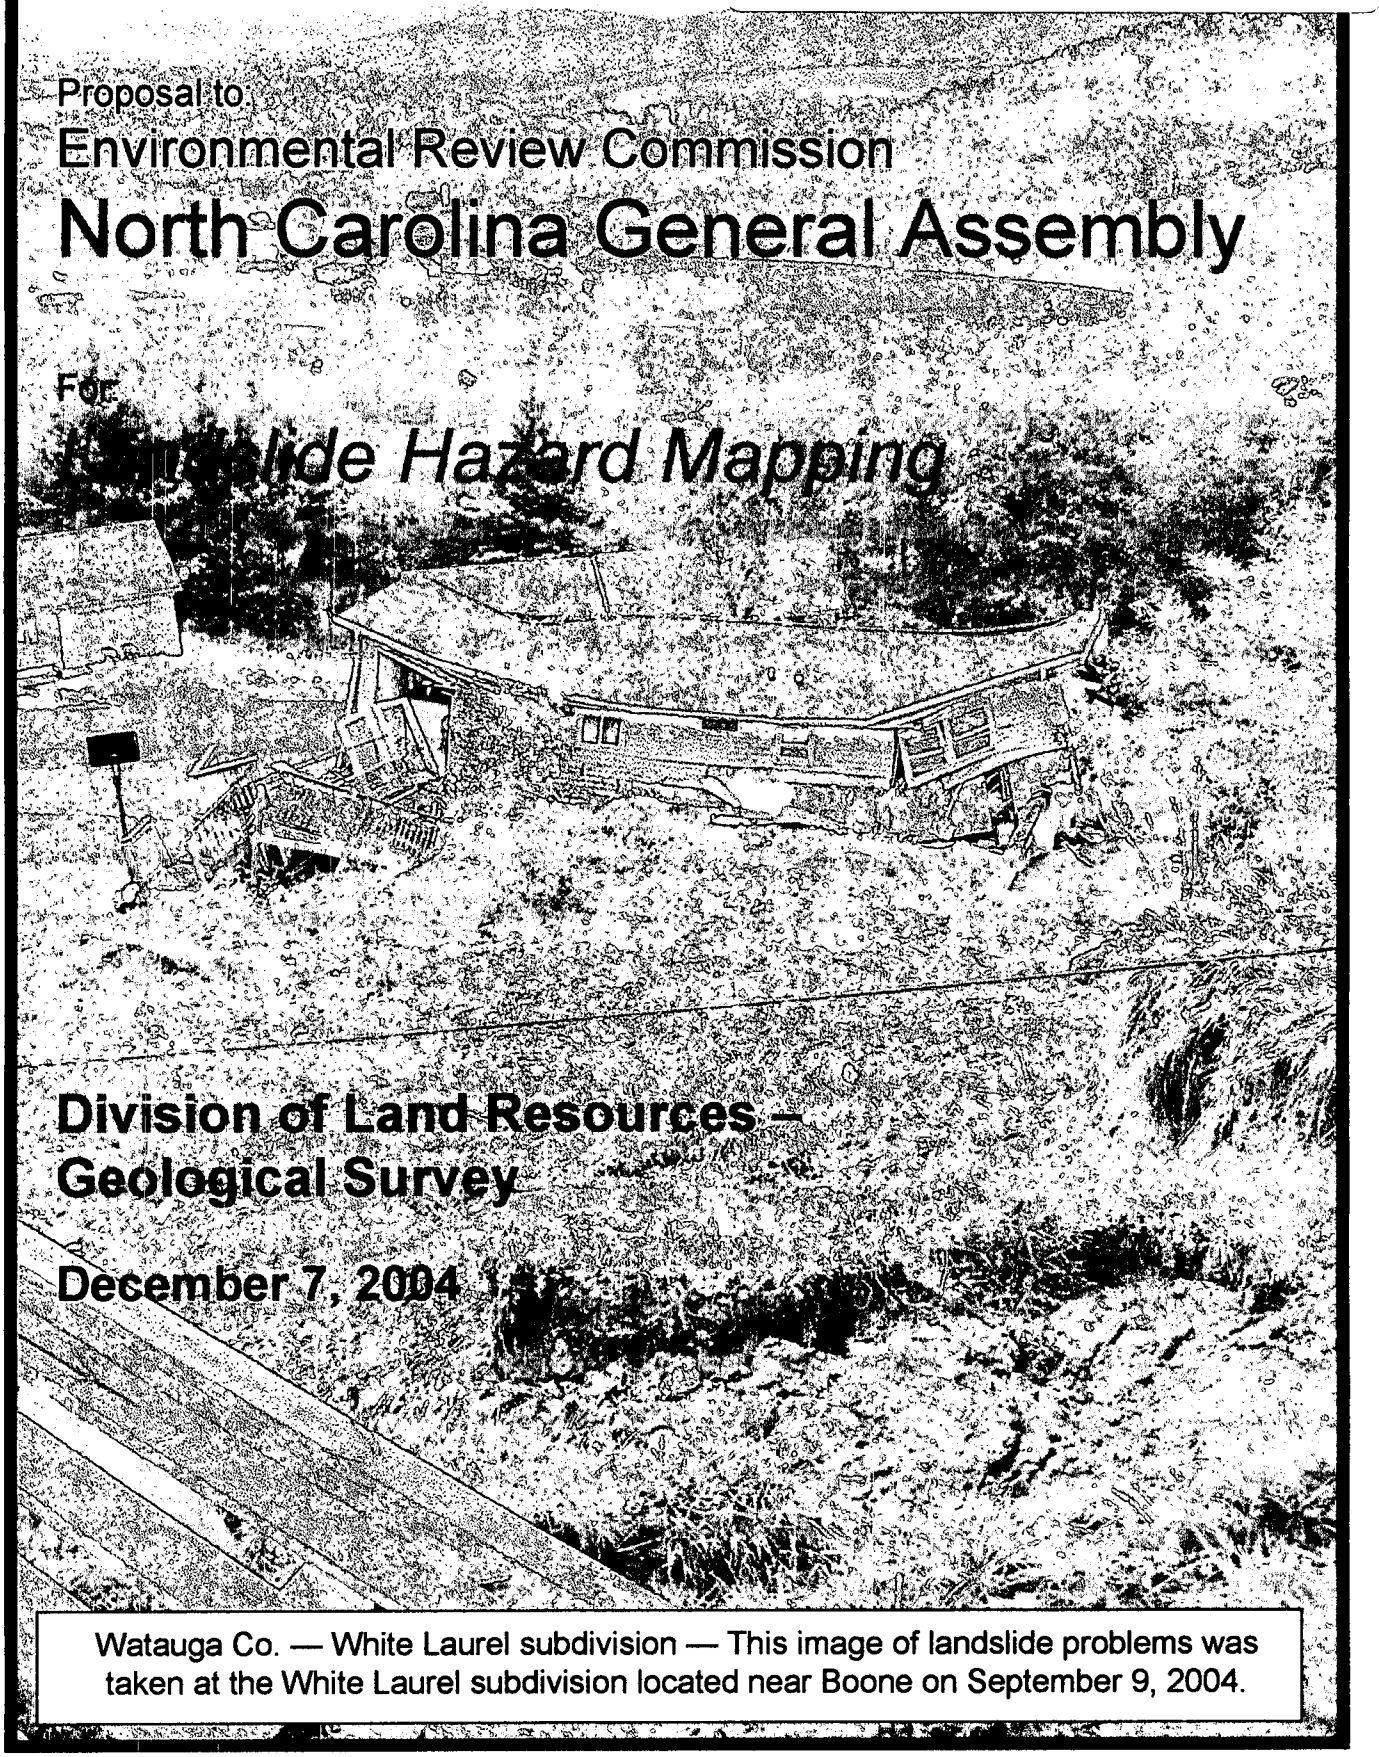
Proposal to:

Environmental Review Commission

North Carolina General Assembly

For:

Landslide Hazard Mapping



Division of Land Resources – Geological Survey

December 7, 2004

Watauga Co. — White Laurel subdivision — This image of landslide problems was taken at the White Laurel subdivision located near Boone on September 9, 2004.

1.0 Overview

The following proposal is in response to a request by the Environmental Review Commission of the North Carolina General Assembly. The main purpose of this proposal is to create a Landslide Hazard Mapping Program in North Carolina. This proposed work would also accelerate the production of a geographic information system (GIS) based geologic hazards atlas for North Carolina.

The state has significant geologic hazards that affect public safety and cause substantial economic loss. The primary geologic hazards facing North Carolina include:

1. Landslides (primarily in the mountains, but also in the Piedmont and Coastal Plain along highway right-of-ways and river valleys);
2. Coastal erosion and flooding from hurricanes and storms;
3. Ground collapse and subsidence above abandoned mines (especially in the Piedmont and mountains) and limestone sinkholes (along the highly populated coast, and to a lesser extent in the western part of the state);
4. High hazard dams (statewide near population concentrations);
5. Earthquake risk (mainly from the Eastern Tennessee, Charleston, S.C., and New Madrid, MO earthquake zones); and
6. Other hazards including acid-producing rock, and naturally occurring contaminants in groundwater, soil, and bedrock (e.g., arsenic, radon, uranium, and asbestos minerals) and high shrink-swell soil.

Landslides are especially dangerous geohazards because they usually occur without warning, can reach speeds in excess of 30 miles per hour, and move boulders that weigh more than 16 tons. Hazards and environmental impacts related to landslides include the threat to public safety, damage to roads and water supply facilities, and degradation of water quality from sedimentation.

This proposal concentrates on developing landslide hazard maps for western North Carolina as key components of the geologic hazards atlas. The information and maps produced by this program will be delivered to the counties, regional planning councils, and the N.C. Division of Emergency Management (NCDEM).

The program will improve information that North Carolina citizens, industry, and state, local, and federal governments can use to better ensure public safety. The program also supports Smart Growth and the DENR strategic targets of Clean Water, Stewardship of Natural Resources, Sustainable Development, and Environmental Awareness/ Outreach, as well as the mission of the North Carolina Geological Survey.

2.0 Landslides

Background. Whereas, the back-to-back tropical storms in western North Carolina during September 2004 that caused over 75 landslides are rare, landslides are not unusual in this part of the state. In fact, landslides occur annually in western North Carolina. Along transportation corridors alone, costs related to landslides average in the

range of $1-3 million annually. Fatalities from landslides occurred in 1916, 1940, 2003, and 2004. Direct costs associated with large landslides (i.e., the 1997 rockslide along I-40) can reach $10 million. Increased population and development on, and below, steep mountainous slopes over the last few decades has increased the risk to public safety from landslides.

Widespread major flooding and landslide events occurred in western North Carolina in 1901, 1916, 1940, 1977, and most recently in 2004, when hurricanes or tropical depressions tracked over the Blue Ridge Mountains and dropped large amounts of rainfall on steep mountain slopes. Prior to 2004, loss of life and significant property damage resulted from these events, even though the area was more sparsely populated at the time. The 1940 hurricane affected most of the southeast and resulted in 26 deaths from flooding and landslides in North Carolina alone. Aerial photographs taken shortly after the hurricane indicate that it triggered well over one hundred landslides. Hurricanes Frances and Ivan triggered over 75 landslides in western North Carolina. These landslides resulted in 5 deaths and 26 damaged or destroyed homes. At least three major landslides occurred along I-40, temporarily blocking the road.

Localized heavy rainfall not associated with tropical storms can also trigger landslides. A December 1990 landslide in Swain County destroyed the chlorinator for the Bryson City municipal water system. A May 2003 storm in Swain and Haywood Counties produced only 6-15 inches of rain over a three-day period, but triggered flooding and over 25 landslides that resulted in costs exceeding $2.5 million.

Landslide Hazard Mapping. Maps that show areas prone to landslides do not exist for western North Carolina. Much of the information that goes into making landslide hazard maps exists (e.g., geologic maps and soil maps), but at different scales, formats, and levels of detail. Information on individual landslides and landslide deposits collected by the North Carolina Geological Survey over the past year is helping to identify some general areas and mountainside conditions susceptible to landslides. New geographic information system (GIS) technology, coupled with field studies can be used to integrate existing data, identify landslide-prone terrain, and develop county-based landslide hazard maps.

Landslide hazard maps show where landslides have occurred in the past, and delineate general areas that are prone to landslide activity and susceptible to landslide damage. Emergency managers can use landslide hazard maps for emergency response planning. Local planners, developers, and homeowners can use landslide hazard maps to make better-informed decisions about the location and design of critical facilities, homes, and developments. Landslide hazard maps will help identify those areas that need an on-the-ground investigation to minimize the potential damage from future landslides.

Hillside stability depends on many interrelated factors including ground slope, shape of the ground surface, soil type and thickness, surface water and groundwater, the underlying bedrock structure, and vegetation among others. There is much variability and uncertainty in all of these factors from site to site in the landscape. Changes in any of these factors can alter the stability of a slope. For these reasons, landslide hazard maps

can show where landslides are more likely to occur, but the maps are not a substitute for an on-the-ground assessment by qualified engineers and geologists.

An important aspect of the work will be to show where landslides and other geologic hazards occur with respect to critical transportation facilities and networks, high hazard dams, and associated infrastructure. Making this information available in an integrated GIS framework will facilitate land use planning, and emergency response and planning.

3.0 Technical Plan and Deliverables

The Geological Survey proposes to develop landslide hazard maps in a GIS format for mountain counties over a five-year period. Years 1-5 will concentrate on landslide hazard mapping, but studies will continue on other geohazards (coastal flooding and erosion, arsenic in groundwater, sinkholes, underground mine collapse, acid-producing rock, shrink-swell soil).

- **Year 1** – Ramp-up year to acquire the needed staff and resources, and produce a pilot study for one county to refine the proposed process and final products.
- **Years 2-5** – Produce landslide hazard maps for 2-3 counties per year.
- **Year 5+** – Produce landslide hazard maps for remaining mountain counties, and applicable Piedmont and Coastal Plain areas, and refine and update existing landslide hazard maps. Redirect efforts to other geohazards.

Landslide hazard maps will consist of the following GIS data layers produced in formats compatible with the needs and requirements of individual counties:

- Landslide susceptibility showing high, moderate, and low landslide potential.
- Landslide and landslide deposit locations.
- Geology (where available).
- Critical soils (where available).
- Slope map.

Inventorying past and recent landslides will be continued statewide, but mainly in western North Carolina. These studies are important for several reasons.

1. To determine what specific geologic conditions make certain areas more prone to landslides;
2. To help identify areas prone to landslides and determine mapping priorities - landslides are likely to reoccur in the same general areas; and
3. To help calibrate GIS-based landslide models - landslides locations should correspond with areas predicted to be unstable.

Landslides identified and mapped, as part of the Geological Survey's Blue Ridge Parkway project will also be incorporated into landslide hazard maps. Landslides occur nearly every year along the Blue Ridge Parkway in North Carolina. The Blue Ridge Parkway is the most visited Park unit in the National Park System, and landslides are a continual threat to public safety and adversely affect local economies.

COUNTY LANDSLIDE HAZARD MAPPING PLAN

	Month 1	Month 2	Month 3	Month 4	Month 5
Determine Mountain County Priorities					
Analyze county population growth data and NCGS landslide database.					
Compilation Phase - Bring Existing Data into GIS Environment					
Consult with County on GIS requirements.					
Assemble existing landslide, geologic, soil, remote sensing, topographic, and critical infrastructure data.					
Data Integration Phase					
Convert data to compatible GIS formats.					
Terrain Analysis Phase					
Preliminary GIS landslide susceptibilty modeling - initial identification of unstable areas.					
Analyze and interpret existing maps and data to guide field verification work.					
Consult with County and other agencies on known problem-special interest areas.					
Field Verification Phase					
Field verify observations made in Terrain Analysis Phase.					
Collect field data on landslides to update database.					
Refine GIS Model Parameters.					
FINAL Map Production Phase					
Rerun GIS models udated and calibrated with field data.					
Delineate downslope areas potentially affected by landslides.					
Produce final landslide hazard map layers (landslide susceptibility; geology; critical soils; slope).					
Management and Peer Review.					
Education - Outreach					
Deliver landslide hazard maps to State and Local Governments - conduct workshops.					
Post maps on NCGS website.					

SCHEDULE NOTES: Month 1 of next county to be mapped overlaps with month 5 of county being mapped.

Year 1 Ramp-up and produce 1 prototype County landslide hazard map.

Years 2-5 Produce 2-3 county landslide hazard maps per year.

Year 5+ Prepare landslide hazard maps for lower priority Piedmont and Coastal Plain counties.

Table 1. Proposed timeline and general sequence of tasks to produce landslide hazard map and accompanying GIS layers for 1 county.

4.0 Cooperation and Coordination with Other Agencies

Funding is included in this proposal to contract with the North Carolina Center for Geographic Information and Analysis (CGIA) for GIS support. Funds are also included to cooperate with the North Carolina Division of Water Quality – Aquifer Protection Section, U.S. Forest Service – Coweeta Hydrologic Laboratory, and the U.S. Geological Survey in the Piedmont-Mountain Resource Evaluation Program. This program involves installing and monitoring groundwater wells at the Coweeta Hydrologic Laboratory in Macon County. Groundwater data from these wells coupled with the long-term weather and hydrologic monitoring data at Coweeta will aid in providing rainfall and groundwater data to use in slope stability modeling of mountain watersheds.

The Geological Survey will coordinate with the N.C. Division of Emergency Management and county emergency management and planning units. We will also coordinate with the Division of Water Quality, N.C. Dept. of Transportation, U.S. Geological Survey, U.S. Forest Service, U.S. Park Service. The Geological Survey will also coordinate with the National Weather Service in issuing landslide advisories in certain weather conditions.

New, high-resolution topographic data programmed to be available through the North Carolina Floodplain Mapping Program will significantly enhance the production of landslide hazard maps. The topographic data produced by the floodplain mapping program will be used where available.

5.0 Schedule and Cost

The attached schedule and budget table summarizes proposed expenditures. It includes staffing, salary, travel, and supplies including computer hardware and software, contracting, and other items needed to accomplish the proposed scope of work.

Year 1 - Ramp Up Under 2004-05 Expansion Budget Request	
	Get Needed Resources
	Arrange for office space
	Hire staff
	Purchase computer resources
	Conduct training
	Continue updating NCGS landslide database
	Conduct statistical analysis on existing landslide data
	Conduct literature review of methods used by other states, countries
	Determine County Priorities
	Conduct Pilot Study for 1 County
	Refine procedure for remaining priority 1 counties
	Publish A Citizens Guide to Landslide Hazards in North Carolina
	Continue Ongoing Geohazards Work Statewide
	Coastal erosion and flooding
	Ground Collapse Above Abandoned Mines
	Sinkholes
	Acid Producing Rock
	Arsenic in Groundwater
	Earthquakes
	Shrink-Swell Soil

Year 2-5 - Make Landslide Hazard Maps for Priority 1 Counties	
	Map 2.5, contiguous Priority 1 counties per year (24 counties @ 2.5 counties/yr)
	Conduct Workshops on using maps at county and state level
	Continue Ongoing Geohazards Work Statewide
	Coastal erosion and flooding
	Ground Collapse Above Abandoned Mines
	Sinkholes
	Acid Producing Rock
	Arsenic in Groundwater
	Earthquakes
	Shrink-Swell Soil

Year 5+	
	Make landslide hazard maps for Priority 2 and 3 counties
	Refine Priority 1 county maps w/ more detailed geologic mapping and analysis
	Maintain database
	Redirect efforts to other Geohazards Statewide
	Coastal erosion and flooding
	Ground Collapse Above Abandoned Mines
	Sinkholes
	Acid Producing Rock
	Arsenic in Groundwater
	Earthquakes
	Shrink-Swell Soil

NORTH CAROLINA
AGGREGATES ASSOCIATION

P. O. Box 30603, Raleigh, NC 27622
Representing Producers and Suppliers in the Aggregates Industry

November 23, 2004

RECEIVED
NOV 29 2004
RESEARCH DIVISION

Mr. George F. Givens
NC General Assembly
Research Division
Legislative Office Building
Raleigh, NC 27603-5925

Dear George:

To follow up with discussions by the Environmental Review Commission on November 19, I'm writing to support additional staff positions for the NC Geological Survey's Geologic Hazards Program. The Commission, having heard State Geologist and DENR-DLR Director, Jim Simons, is now informed of the severe budget constraints facing the Survey and its important programs.

We understand that DENR administrative staff has approved an expansion budget request for the Survey. It is my hope that the Environmental Review Commission could include, as a part of its package of bills for the 2005 Session, a recommendation for additional appropriations with which to expand the NCGS's Geologic Hazards Program in accordance with recommendations from the NC Geological Advisory Committee and consistent with recommendations from DENR administrative staff.

Thank you for consideration.

Sincerely,

Frederick R. Allen
Executive Director

Cc: Jim Simons

Department of Environment and Natural Resources

Division of Land Resources

Presentation to the Environmental Review Commission

December 7, 2004

Jim Simons, Director
(919) 733-3833

I. Overview of Division Responsibilities

A. Geodetic Survey

- Establish and maintain the State Plane Coordinate System
- Establish vertical control (benchmarks)
- Boundary surveys for the State and counties
- Floodplain mapping
- Provide education outreach in land surveying, geodesy, and new mapping and positioning technologies

B. Geological Survey

- Examines, surveys and maps the Geology of the State
- Provides education outreach in Earth Science
- Collaborates with USGS & EPA on effects of geology on coastal processes, underground contaminant migration and landslides
- Publishes reports and maps
- Administer the NC Oil and Gas Conservation Act of 1946

C. Land Quality Section

Permitting, Technical Assistance, Inspections, Enforcement

- Dam Safety Program
- Mining Program
- Sediment Control Program

II. Geodetic Survey

A. Year-End Highlights of Accomplishments

- Established or re-established hundreds of horizontal and vertical benchmarks to assist surveying statewide.
- Served as one of three key agencies to produce new Digital Flood Insurance Rate Maps.
- Surveyed 56 miles of county boundaries at the counties' request.
- Revived the NC/SC Boundary Commission and contracted and provided oversight for the surveying of 72 miles of NC/SC and NC/VA state line boundary.
- Conducted 13 technology transfer workshops on Global Position System (GPS), state plan coordinate system, floodplain mapping program and LIght Detection and Ranging (LIDAR).
- Continued to Expand the GPS system real time kinematic network that provides real time GPS data via wireless internet connections.
- Added 11 new GPS base stations to make it easier for surveyors, engineers, contractors, GIS professionals, government agencies and emergency responders to access accurate GPS for boundary surveys and other mapping applications.
- Worked with U.S. Coast Guard, DOT and A and T State University to build a National Differential Global Positioning System tower in Greensboro that provides GPS differential correctors to western North Carolina.
- Implemented the National Height Modernization System in North Carolina using GPS and traditional leveling to obtain accurate elevations.

B. Trends and Issues

- Surveyors, engineers, GIS professionals, contractors, planners, emergency management agencies will benefit from access to more accurate GPS correction information in real time.
- Increased use of Geographic Information System (GIS) has expanded the users of geodetic data. This trend will continue to grow as this technology is expanded to other areas in government and the private sector.
- The use of the National Height Modernization System will continue to expand.
- The re-survey of NC/SC boundary in greater Charlotte/Mecklenburg area. likely to be controversial.

III. Geological Survey

A. Year End Highlights

- Provided emergency technical assistance to local and state emergency management personnel to determine immediate and potential threat to lives and properties of landslides resulting from the severe rainfalls of hurricanes Frances and Ivan. The response included inspection of three landslides that had destroyed or endangered houses, and, in one case, caused fatalities; participated in technical review committees to determine causes of landslides and where other landslides may happen; presented information on landslides to local government and interest groups; prepared several reports on the landslides causing damage and fatalities; posted locations of known landslides and useful public safety information to news media and Division's web page.
- Completed geologic mapping of approximately 215 square miles in the north central piedmont and in the Asheville vicinity. Also mapped the geology of the central part of the Blue Ridge Parkway.
- Started initial work on a geologic hazards atlas of North Carolina.
- Continued work with the U. S. Geological Survey on determining subsurface geology of Outer Banks and Cedar Island and completed draft of geomorphic map of Cape Hatteras.
- Continued work with the U. S. Geological Survey and the Division of Water Quality to determine ground water pollution potential of animal waste nutrients through the aquifer in the central coastal plain.
- Participated with the Office of Environmental Education's Earth and Environment Science Institute in Randleman working with over 25 high school teachers on curriculum-based environmental concepts.
- Answered public inquiries and performed public outreach through a number of presentations; received hundreds of requests for information; and received over 2.4 million hits on the Geologic Survey's web page.

B. Trends and Issues

- Geohazards, such as landslides, sinkholes, mine subsidence and toxic trace elements, will become more of a problem as population grows into areas previously considered not suited for development.

- Collaboration with Geodetic Survey, Division of Emergency Management, the Center for Geographic Information and Analysis and others will facilitate database gathering of geohazards.
- Survey must depend upon matching grants from U. S. Geological Survey and other federal agencies for funding for staff travel, equipment, supplies, rent, etc.
- Federal grants do not generally provide funding for publishing or other distribution of their funded projects.
- Grants are based on federal priorities and not necessarily state priorities.

IV. Land Quality Section

A. Year End Highlights

- Provided dam safety emergency response to hurricanes Frances and Ivan, including over 150 inspections, technical oversight of three emergency dam breaches, round the clock monitoring of several potentially dangerous dams, providing dam safety inventory information to emergency management personnel and staffing the Emergency Operations Center.
- Conducted workshops on erosion and sediment control for several hundred contractors, design professionals and local government personnel.
- Performed over 1,760 inspections of dams to determine the potential threat to public safety and initiated corrective actions, where necessary.
- Performed over 14,000 environmental inspections of construction sites and over 650 inspections of mines, and initiated compliance actions, if necessary.
- Issued approvals for over 3,020 erosion and sedimentation control plans, 300 mining permits and 199 dam safety permits.
- Implemented the Express Permitting Program for sedimentation plan approvals in the Wilmington and Raleigh Regional Offices.
- Released 4,323 acres of reclaimed mine land.
- Developed an Internet based, statewide database of permitted mines and dams.
- Assisted the Division of Emergency Management in a risk assessment plan for geohazards.
- Responded to hundreds of public inquiries on erosion and sediment control, dam safety and mining.

B.Trends and Issues

Dam Safety

- 5,000 dams under state jurisdiction and growing, including 1,000 considered in high hazard potential classification (among highest of any state in nation).
- Dams are becoming more dangerous over time as man made components deteriorate and more development occurs downstream.
- Experience has shown public safety can be improved by proper dam construction/repair, routine dam inspections and emergency action plans.

Mining

- 950 permitted mines statewide and growing.
- Increasing land use conflicts between mining and development.
- Number of permitted mines has tripled while permitting and inspection staffing has remained the same.
- Increased opportunities for public participation into mine permitting process have increased public awareness, but have also slowed the permitting process and increased public complaints against mining operations.

Sediment Control Program

- Approximately 8000 active construction sites under state program jurisdiction.
- Tremendous amount of land disturbing activities in state.
- More development in areas of high risk for offside sedimentation damage.
- Need for more regular monitoring to ensure erosion and sediment control measures are installed and maintained – including more good local programs, self-inspections, etc.
- Need to put increased emphasis on preventing erosion rather than trapping sediment, and to improve current erosion and sediment control measures.

Report on Inactive Animal Waste Lagoons
NC Division of Soil and Water Conservation
December 7, 2004

Recap 2000 report – Included ranking process and survey; identified 1,142 inactive lagoons on 745 farms in 76 counties. Classified 39 as high-risk; estimated cost for closure of high-risk lagoons ($1.5M) or for assessment of all ($2M). Recommended incentive (100% cost share) approach over 3 years.

Outcome – no new funds appropriated; districts proceeded using normal cost share funds in voluntary programs.

Update 2004 – Closure of inactive animal waste lagoons is being done by local Soil and Water Conservation Districts. Overall, **133** inactive lagoons have been closed since 2000, with an added **79** scheduled to be closed this program year. An added **54** operations have gone inactive since 2004; 9 have been re-activated.

Of **39** high-risk lagoons in 24 counties identified in our 2000 report, **12** have been closed, with another 2 pending, 1 with management plan, and **1** reactivated. Thirty-six percent of the high-risk lagoons are closed or are under contract to be closed.

The remainder of those lagoons closed (about **120**) were from other categories on the 2000 list or from newly inactivated lagoons.

Funding used:

1. North Carolina **Agriculture Cost Share Program** – 69 closed since 1/2000; 6 under contract; includes 35 counties; cost $1M; new provision for limited resource farmers allows up to 90% cost share.
2. USDA **Environmental Quality Incentive Program** (EQIP) – 98 contracts since 2000; now at 50% cost share.
3. **Smithfield Agreement/NC Foundation** for Soil and Water Conservation – two grants (totaling $1M) since 2002; participated in contracts for closure of 45 inactive lagoons (28 closed).
4. **Clean Water Management Trust Fund** – Chowan and Franklin counties participation; some special cases with lack of responsible party/lagoon abandonment.

Note that many lagoon closures are cooperatively funded by multiple sources due to high costs. A single closure may consume a district's entire cost share allocation. Note that lagoon size varies (especially older ones), and cost is variable. Availability of contractors and fees charged also vary.

Cumulative Inactive Lagoon Survey, 2000 - 2003

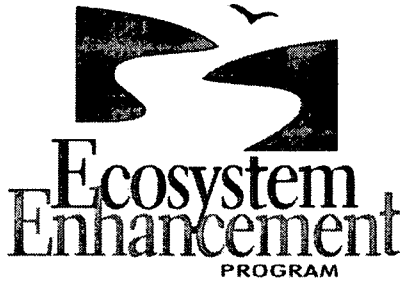
Presentation to
Environmental Review
Commission

December 7, 2004



Program Overview

- Growing in Responsibility
- Increasing Productivity
- Managing Funds/Watching Expenditures

Program responsibility

- EEP
  - Combined mitigation programs of WRP & DOT
- Regulatory Coordination
  - Joint WRP and DOT Regulatory Coordination
- Manages funds as per G.S. 143-214.13

Productivity

(Funds 2980,2981,2982)

- Permits provided for
  - Since 1998 to date 948
  - Last SFY 362
- SFY 03/04 Breakdown (No. payments)
  - Private Sector 63%
  - NCDOT 25%
  - Other 12%
- SFY 03/04 Payments ($)
  - Private Sector 19%
  - NCDOT 78%
  - Other 3%

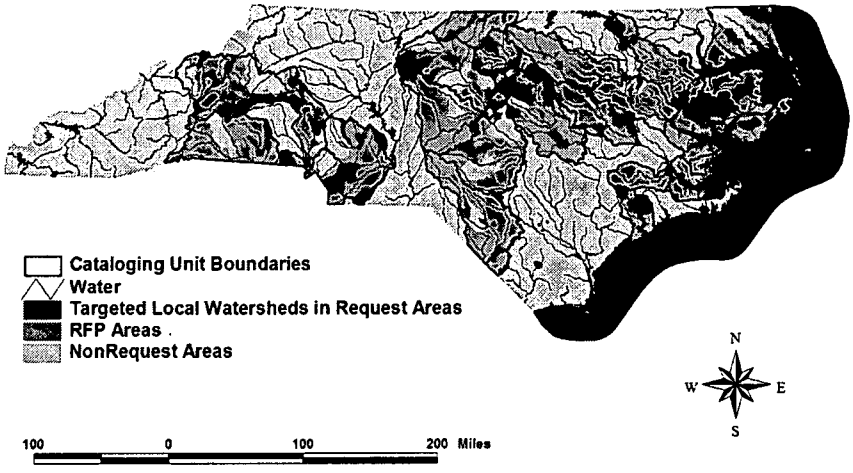
Productivity

	Total Accepted 6/30/04	Total Due 6/30/04	Total Produced 6/30/04	Recently awarded	Total To date
Streams (Feet)	319,650	227,834	253,550	64,710	318,290
Wetlands (Acres)	367	305	402	69	471
Buffers (Acres)	369	244	193	75	268

Primary Mitigation Procurement Methods

- Full Delivery Providers
- Design-Bid-Build
- Watershed-based Project Development
- Inter-agency cooperative efforts

2004 EEP Request For Proposal Areas



Solicitations Underway

Basin	Stream	Wetland	Cst'l Marsh	Buffer
Broad	35,000	70		
Cape Fear	178,000	222		90
Catawba	115,000	235		
F. Broad	5000	5

Yadkin	26,000	25		
Total	450,000	933	12	395

Costs factors and fund standing

Stream Restoration

Rural Project Example: Little Bugaboo

Purchase	$ 4,125
Design	$ 103,889
Construction Mgmt.	$ 83,310
Site Restoration	$ 399,400
Long-Term Mgmt./ Monitoring	$ 66,280
Length (feet)	6,600
Cost per linear foot	$ 100
Total Cost	$ 657,004

Stream Restoration
Urban Project Example: Hominy Swamp

Id & Purchase	$ 4,950
Design	$ 123,903
Construction Mgmt.	$ 12,600
Site Restoration	$ 322,618
Long-Term Mgmt./ Monitoring	$ 54,000
Length (feet)	2232
Cost per linear foot	$ 232
Total Cost	$ 518,071

Stream Restoration FY 03-04

- EEP Completed 27 stream restoration projects
- Restored 115,312 linear feet of stream
- Ave. cost per linear foot: $139.28
- Cost vary for urban and rural projects

Average per linear foot cost:

- Urban projects: $182.47
- Rural projects: $112.62

Urban Projects – *Why the Added Expense?*

- Must work with roads, existing utilities
- Shorter stretches of stream for restoration
  - Higher density of land ownership
  - Smaller parcel size
- No "economies of scale" with smaller projects
  - Initial mobilization of equipment is significant portion of costs

Wetland Restoration Costs

- No independent wetland projects produced last SFY
- Existing rates for non-riverine appear appropriate
- Evaluating data for riverine wetland systems, latest awards indicating upward adjustment needed

Wetlands Trust Fund
Restoration Account 2980

Balance 7/1/03		**$1,978,457**
Revenue (FY03-04)		$61,011
Interest	$61,011	
Expenditures		$148,434
Design/Construction Management	$148,434	
Balance 6/30/04		**$1,891,034**
Current Contractual Encumbrances		**$1,815,719**
Balance of Unencumbered Funds		**$75,315**

Wetlands Trust Fund
Compensatory Mitigation Account 2981

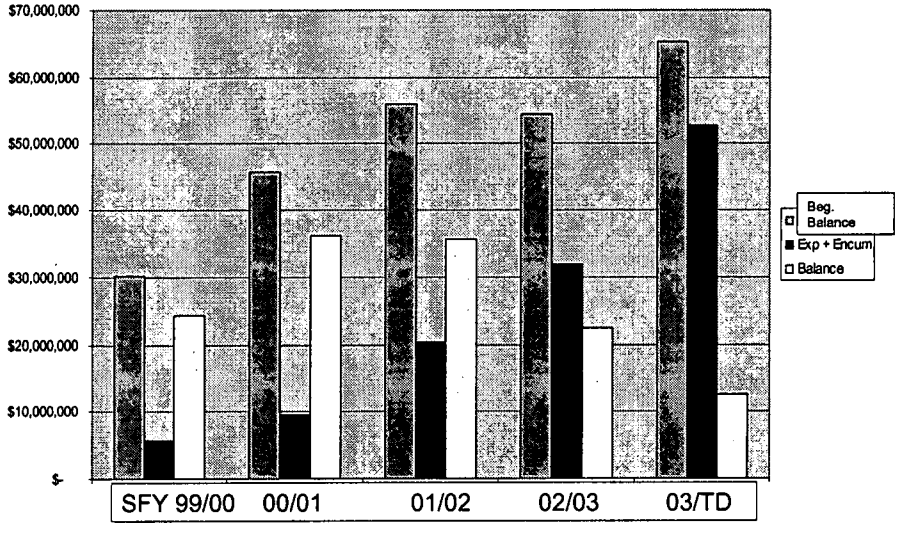
Balance on 7/1/03		**$40,452,387**
Revenue		$20,541,392
Compensatory Mitigation Payments	$17,342,162	
Nutrient Offset Payments	$1,685,752	
Interest	$1,513,478	
Expenditures (FY03-04)		$14,150,989
Balance on 6/30/04		**$46,842,790**
Current Contractual Encumbrances		**$17,648,302**
Balance of Unencumered Funds		**$29,194,488**

Wetlands Trust Fund
Riparian Buffer Restoration Account 2982

Balance 7/1/03		**$5,513,590**
Revenue		$5,494,285
Compensatory	$5,235,823	
Interest	$258,462	
Expenditures		$325,017
Balances 6/30/04		**$10,682,858**
Current Contractual Encumbrances		**$678,282**
Balance of Unencumbered Funds		**$10,004,576**

Beginning Balance-Obligations-Balance

Funds (2980-2981) To Date



Summary

- Last year was significant in terms of activity
- We have increased production
- Rely heavily of private sector for the work
- Comprehensive report next year to include a increased DOT responsibilities

www.nceep.net

Ecosystem Enhancement PROGRAM

The North Carolina Ecosystem Enhancement Program Annual Report On In-lieu Fee Programs

Executive Summary: July 1, 2003 – June 30, 2004

Introduction

The past fiscal year was significant for the NC Wetlands Restoration Program (NCWRP). During that time, the NCWRP combined forces with the compensatory mitigation resources of the NC Department of Transportation to form the Ecosystem Enhancement Program (EEP). This year's annual report to the Environmental Review Commission (ERC) presents the EEP's progress in meeting the goals and requirements of the NCWRP's enabling legislation but does not present details on the EEP. It is the Department of Environment and Natural Resource's intent to provide the ERC with an annual report in late 2005 that presents a comprehensive characterization of the EEP in its entirety, not just those components related to the NCWRP legislation.

Watershed Planning

The EEP continues to place restoration project implementation in watersheds with demonstrated need of attention. To ensure that program projects will generate the greatest environmental benefit, EEP develops plans at the river basin scale and at the local scale to target restoration activities. During fiscal year 2003 – 2004 (FY 03-04) the EEP completed Watershed Restoration Plans for the Lumber, Tar-Pamlico, and Catawba river basins in accordance with the NC Division of Water Quality's basinwide planning schedule. In addition, development of Watershed Restoration Plans for the French Broad, New and Cape Fear river basins were initiated. The EEP also has 20 detailed planning initiatives (Local Watershed Plans) underway all across the state to identify what specific actions are necessary to restore and protect small local watersheds. These studies allow the program to more precisely locate the most environmentally beneficial and cost effective restoration projects.

Project Implementation

At the end of FY 03-04, 70 projects were at or beyond the initial design phase. Twenty-five projects have been completed, resulting in the restoration, enhancement or preservation of 462.7 acres of wetlands, 66,832 linear feet of streams and 156.5 acres of riparian buffer. The remaining projects are currently in the design phase and will be constructed during FY 04-05. Collectively, these 70 projects will result in the restoration, enhancement and preservation of 960.2 acres of wetlands, 208,730 linear feet of streams and 342.4 acres of riparian buffer.

These projects are located throughout North Carolina in 11 different river basins and 34 counties. Seventy-three percent of these projects are located within Targeted Local Watersheds that have been identified by the EEP's planning process as watersheds in need of restoration activities.

Trust Funds

By mandate of the NCWRP enabling legislation, the EEP manages three accounts within the Wetlands Trust Fund: Account 2980 – Wetland Restoration; Account 2981 - Compensatory Mitigation; and Account 2982 – Riparian Buffer.

During the last fiscal year, the EEP has continued to accelerate expenditures of

funds toward the identification and implementation of restoration projects. Expenditures and encumbrances from funds 2980 and 2981 were in excess of $54 million for the fiscal year, the largest expenditure reported since the establishment of the NCWRP.

During FY 03-04, the EEP received 98 payments for compensatory mitigation associated with Section 404/401 permits, permitted riparian buffer impacts and nitrogen offset payments. Sixty-two of the payments (63 percent) were received from the private sector, 24 payments (25 percent) were received from NCDOT and 12 payments (12 percent) were received from other state, federal and local government agencies.

Project Costs

The EEP continues to track the costs of stream and wetland restoration projects and compares them to the fees established in rule 15ANCAC 02R .0402. Data for completed projects indicate that the average cost of stream restoration per linear foot is $182 for projects in urban settings and $112 for projects in rural settings. Though these results differ from the recently revised fee schedule of $200 per foot, the discrepancies lie in the program's ability to encourage donations of property. Because the established in-lieu fees must account for costs associated with land acquisition and many of the program's projects will be in the urban setting to maintain proximity to the impacts that are being offset, the EEP believes that the current fee schedule for stream restoration is appropriate.

No additional cost information related to wetland restoration through the in-lieu fee program became available during this past fiscal year. Data from projects external to the program and additional requirements for pre-monitoring of restoration sites suggests that the existing fee of $24,000 per acre may be too low. EEP staff intend to collect applicable cost data and evaluate whether a revision to the fee for riparian wetlands is necessary.

Highway Use Tax Based on Efficiency/ Vehicle Registration Based on Vehicle Miles Traveled

Preliminary Report on ERC Study

December 7, 2004

Background

- S.L. 2004-161, Sec. 19.10 requires that the Commission study three issues:
  - Whether the State should modify the current highway use tax so that all or a portion of the highway use tax paid on a private passenger vehicle is based on the fuel efficiency rating of the vehicle.
  - Whether the State should modify the current vehicle registration fee so that all or portion of the annual vehicle registration renewal fee for a passenger vehicle is based on the vehicle miles traveled by the vehicle.
  - Whether the modifications should be made on a revenue-neutral basis or should be made so as to generate additional revenue to be used to fund initiatives designed to improve air quality and the efficiency of the transportation system in the State.

Today's presentation

- Describes the process by which staff plans to gather information for ERC consideration
- Receive ERC concurrence on the approach, or guidance on preferred directions

Basic approach

- Identify affected/interested State agencies and other parties
- Identify the options
  - Identify pros and cons of each option
- Identify considerations for implementation
- Present this information to the ERC for its consideration/decision

Affected/interested State agencies and other parties

- DENR
- DOT/DMV
- Revenue
- Energy
- Car dealers
- AAA
- Environmental groups
- Others?

Identify the options

- Meeting with stakeholders, talking with out-of-state peers, searching the web for previous efforts

(continued on other side)

    - Include benefits and costs
        - Environmental, energy conservation, transportation efficiency
    - Which options are feasible for near-term implementation
    - How significant must the modifications be to influence motorist behavior
- Discussions among NC stakeholders to identify pros and cons of each option

Identify considerations for implementation

- "Assume" that any of the options might be implemented
- What would be the challenges for implementation
    - Identify hurdles to success and efficiency
    - Primarily focused on State agencies with implementation roles
    - Examples
        - How to determine the fuel efficiency rating for a specific vehicle
            - Prefer automated approach rather than a clerk manually searching tables and making judgement calls
            - How to determine historical ratings
        - How to determine the vehicle miles traveled
            - Emissions inspections record mileage electronically
            - Safety-only counties record mileage manually
            - In neither case is the data currently QA'd
        - What are the unintended consequences
            - Highway use fee structure itself might be revenue neutral, but improved fuel efficiency would decrease fuel tax receipts
            - If highway use fee is too high, it could delay fleet turnover
- How would any increase in revenue be used?

Schedule

- Initial meetings have already been held
- Between now and the Holidays
    - Research on available options and first draft of report
- Jan 2005
    - Finalize report
    - Present to ERC

Presented by:

- Donnie Redmond, Division of Air Quality
- 919-733-1481
- donnie.redmond@ncmail.net

State Facilities Water Savings Projects

Environmental Review Commission

December 7, 2004

Larry Shirley
Director
State Energy Office

12-7-04

State Energy Office ENERGY

State Government Water Usage

- **2004 Water-Sewer expenditures = $28.5 million**
- **Estimated daily usage 15.6 MGD**
- **46 gallons per day per occupant**

12-7-04

State Energy Office ENERGY

State Water-Sewer Rates

- **100+ different local & municipal water companies**
- **Widely varying statewide rates, water & sewer, irrigation**
- **Sewer cost typically multiplier of water rates:**
  sewer cost = 1.5 to 2.5 times water cost
- **Commercial water-sewer rates vary $3.00 - $28.00 per Kgal.**

Source: League of Municipalities

12-7-04

State Energy Office ENERGY

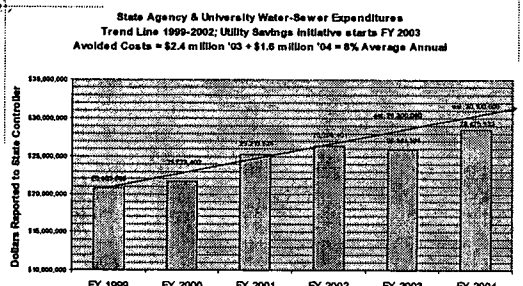
New Cost Increase: Stormwater Fees

- **Approximately seven municipalities charge stormwater fees**
- **Virtual "property tax" based upon square feet of impermeable space: parking lots, buildings**
- **Added to water bills: increases total water cost**
- **Possible savings via rainwater catchment- grey water and irrigation systems**

12-7-04

State Energy Office ENERGY

State Government Water-Sewer Usage: Bucking the Trend



12-7-04

State Energy Office ENERGY

Utility Savings Initiative Conservation Awareness Training

- **Joint statewide training 2002-2004 DENR/Water System Protection Team DENR/CC&PS**
- **2002 Drought: HB 1215 10% reduction in water use; Exec Order 26 non-essential ban; long term water plans**
- **Conservation Awareness Teams established in partnership with Sustainability/NC Project Green teams per Executive Order 156-1999**

12-7-04

State Energy Office ENERGY

Water Conservation Measures

- Water conservation measures:
  - Leak reporting
  - "Don't be a drip- turn it off!" stickers
  - Facilities personnel training
    - Cooling Tower efficiency
    - Boiler condensate return
  - Shower and faucet flow reducers
  - Waterless urinals (UNC)

12-7-04

State Energy Office ENERGY

Successes in State Government

- Water Billing refunds
  - DHHS $60,000 refund
  - NC A&T $75,000 refund
- Only pay sewer on water that ends up in the sewer
  - Zoo saving $200,000 per year with sewer meter
- Irrigation meters: Install water meters for irrigation only, or drill irrigation wells and/or use drought-tolerant plants and grass

12-7-04

State Energy Office ENERGY

Successes in State Government

Cooling Tower Sewer Cost Credit

- Approximately 50% water evaporates in a cooling tower- doesn't go to sewer
- Requires agreement with municipal water company
- Dept. of Correction metered one tower saving $7,200 annually, cost approximately $1,000

12-7-04

State Energy Office ENERGY

Successes in State Government

- **DHHS John Umstead Hospital, Butner**
- **Piped cooling water from 4 water-cooled ice machines from drain to cooling tower: reused cooling water**
- **Saved 429,000 gallons and $2,016 annually**

12-7-04

State Energy Office ENERGY

New for 2004

Performance Contracting

"Energy Savings Contracts for Governmental Units"

- **General Statute G.S. 143-64.17 (2002)**
- **Amended 2003**
- **Previously K-12 and Community Colleges**
- **No Capital Costs/Guaranteed Savings**
- **$50 million to start, 12 year max. contracts**
- **List of 15 Qualified Energy Service Companies**

12-7-04

State Energy Office ENERGY

Performance Contracting Activity Local Government, K-12, Community Colleges

- **1998 - $ 4.1 million in contracts**
- **1999 - $ 1.6 million " "**
- **2000 - $ 0.8 million " "**
- **2001 - $ 5.9 million " "**
- **2002 - $10.6 million " "**
- **2003 - $13.2 million " "**

Total $ 36.2 million

12-7-04

State Energy Office ENERGY

Performance Contracting Activity State Government and Universities

- UNC-Greensboro
- Museum of Art
- Downtown Complex and Central Chiller Loop
- Values range $2.5 million to $10 million
- $20 million total proposed contracts
- $250+ million in potential performance contracts
- Not all proposals included water measures

12-7-04

State Energy Office ENERGY

Potential State Water Savings

- Total State Water-Sewer Bill $28.5 million
- 11% of Total State Utility Bill of $256 million

(electric, gas, fuels, water-sewer)

- $5.8 million of potential water savings under performance contracting

12-7-04

State Energy Office ENERGY

Recommendations

- Amend Performance Contracting statute GS 143-64.17 to specifically include water savings measures
- Increase current total contract cap of $50 million to $75 million, or remove altogether
- Include water measures in GS 143-64.10-16, Energy and Water Conservation in Public Facilities

12-7-04

State Energy Office ENERGY
